

Black Point Quarry Project
Municipality of the District of Guysborough, NS

Environmental Impact Statement

TABLE OF CONTENTS
and
TABLE OF CONCORDANCE

Vulcan Materials Company

February 2015

TABLE OF CONTENTS PART 1 (Sections 1-5)

1.0	PROJECT INTRODUCTION	5
1.1	Report Organization	5
1.2	Project Overview.....	6
1.3	Project Location.....	9
1.4	Geographical Setting.....	13
1.5	Ecological Overview.....	15
1.6	Participants in the Environmental Assessment	16
	1.6.1 Proponent.....	16
	1.6.2 Corporate Information.....	16
	1.6.3 Safety Health and Environmental Policy.....	18
	1.6.4 Environmental Consultants	19
	1.6.5 Aboriginal Groups	20
	1.6.6 Community and Environmental Organisations	21
1.7	Project Schedule.....	23
1.8	Purpose of the Project.....	23
1.9	Benefits of the Project.....	24
2.0	REGULATORY FRAMEWORK	26
2.1	Federal.....	26
	2.1.1 Canadian Environmental Assessment Act (CEAA 2012)	26
	2.1.2 Canadian Environmental Protection Act 1999.....	26
	2.1.3 Fisheries Act.....	27
	2.1.4 Migratory Birds Convention Act, 1994	27
	2.1.5 Species at Risk Act.....	27
	2.1.6 Canada Shipping Act, 2001	28
	2.1.7 Oceans Act.....	28
	2.1.8 Navigation Protection Act	28
2.2	Provincial	28
	2.2.1 Environmental Assessment.....	28
	2.2.2 Harmonization.....	29
	2.2.3 Resource Management Initiatives	29
	2.2.4 Permits and Authorizations	30
2.3	Municipal	32
2.4	Policies and Guidelines.....	32
2.5	First Nations.....	34
3.0	PROJECT DESCRIPTION	35
3.1	OVERVIEW OF PROJECT COMPONENTS AND SITE LAYOUT.....	35
	3.1.1 Access Road	37
	3.1.2 Open Pit Quarry.....	37
	3.1.3 Processing Plant.....	50
	3.1.4 Stockpiles, Overburden and Crusher Fines.....	65
	3.1.5 Administrative Buildings.....	65
	3.1.6 Transmission Line Tie In.....	65
	3.1.7 Marine Terminal	66
	3.1.8 Waste Water Treatment System (Other Utilities).....	71
3.2	CONSTRUCTION PHASE.....	71
	3.2.1 Construction Activities.....	71

3.2.2	<i>Geotechnical Investigations and ARD</i>	72
3.2.3	<i>Site Preparation, Cut and Fill, Blasting</i>	73
3.2.4	<i>Access Road and Transmission Tie-in</i>	77
3.2.5	<i>Processing Plant and Laydown Areas</i>	77
3.2.6	<i>Marine Terminal</i>	78
3.2.7	<i>Construction Water Use and Water Management</i>	79
3.2.8	<i>Construction Related Noise</i>	79
3.2.9	<i>Construction Related Traffic</i>	79
3.2.10	<i>Construction Schedule</i>	80
3.3	OPERATIONS PHASE	80
3.3.1	<i>Quarry Operation</i>	80
3.3.2	<i>Processing Plant Operation</i>	84
3.3.3	<i>Operational Water Requirements</i>	84
3.3.4	<i>Offloading to Ships</i>	85
3.3.5	<i>Liquid Fuel Delivery and Storage</i>	85
3.3.6	<i>Hazardous Materials Management</i>	86
3.3.7	<i>Wastewater Management</i>	86
3.3.8	<i>Other Waste</i>	88
3.3.9	<i>Operation Related Noise and Light</i>	88
3.3.10	<i>Air Emissions</i>	90
3.3.11	<i>Marine Vessel Operations</i>	92
3.3.12	<i>Emissions to Atmosphere from Marine Operations</i>	95
3.4	DECOMMISSIONING PHASE	97
3.4.1	<i>Transfer of Ownership and Control</i>	97
3.4.2	<i>Rehabilitation Plan</i>	98
3.4.3	<i>Site Description at Closure</i>	99
3.4.4	<i>Reclamation Objectives</i>	99
3.4.5	<i>Reclamation Goals</i>	100
3.4.6	<i>Removal of Equipment and Infrastructure</i>	100
3.4.7	<i>Removal of the Marine Terminal</i>	101
3.4.8	<i>Site Rehabilitation</i>	101
3.4.9	<i>Reclamation Phasing Timeline</i>	102
3.5	ACCIDENTS AND MALFUNCTIONS	104
3.5.1	<i>Fuel and Hazardous Materials Spills</i>	104
3.5.2	<i>Erosion and Sediment Control Failure</i>	106
3.5.3	<i>Vehicle and Vessel Collision</i>	107
3.5.4	<i>Fire</i>	107
3.5.5	<i>Health, Safety and Environmental Management</i>	108
4.0	ALTERNATIVES TO THE PROJECT	112
4.1	<i>Do Nothing Alternative</i>	112
4.2	<i>Assessment Methodology</i>	112
4.3	<i>Alternative Quarry Locations</i>	113
4.4	<i>Rock Extraction Method</i>	114
4.5	<i>Development and Transportation</i>	114
4.6	<i>Marine Terminal Locations</i>	115
4.7	<i>Marine Terminal Construction Methods</i>	117
4.8	<i>Stockpile Locations</i>	119
4.9	<i>Waste Management Facilities</i>	119
4.10	<i>Electrical Supply</i>	121

4.11	The Preferred Approach	122
5.0	ENVIRONMENTAL EFFECTS ASSESSMENT METHODOLOGY	127
5.1	Overview	127
5.2	Application of the Precautionary Approach.....	127
5.3	Valued Components Selection.....	128
5.4	Likely Project-Environment Interactions.....	129
5.5	Project Boundaries	135
	5.5.1 Temporal Boundaries	135
	5.5.2 Spatial Boundaries	135
	5.5.3 Technical Boundaries.....	138
	5.5.4 Administrative Boundaries	138
5.6	Impact Prediction.....	138
5.7	Environmental Effects Assessment	139
5.8	Mitigation and Residual Effects	139
5.9	Residual Effects and the Determination of Significance.....	142
5.10	Cumulative Environmental Effects	143
5.11	Follow Up and Monitoring	144
5.12	Effects of the Environment on the Project.....	144
5.13	Description of the Retained VCs.....	145

TABLES PART 1 (Sections 1-5)

Table 1.1:	Black Point Quarry Property Identification Numbers.....	9
Table 1.2:	Proposed Boundary Coordinates	11

TABLE OF CONTENTS PART 2 (Section 6)

6.0	EXISTING CONDITIONS	9
6.1	Geophysical Environment.....	9
6.1.1	<i>Physiography, Geomorphology and Topography</i>	<i>9</i>
6.1.2	<i>Soils/Sediment.....</i>	<i>12</i>
6.1.3	<i>Surficial Geology.....</i>	<i>14</i>
6.1.4	<i>Regional Geology</i>	<i>16</i>
6.1.5	<i>Local Geology.....</i>	<i>19</i>
6.1.6	<i>Acid Rock Drainage (ARD) Potential.....</i>	<i>20</i>
6.1.7	<i>Seismic Activity.....</i>	<i>20</i>
6.1.8	<i>Isostatic Uplift and Subsidence.....</i>	<i>25</i>
6.1.9	<i>Landslip Potential.....</i>	<i>25</i>
6.2	Water Resources	26
6.2.1	Surface Water.....	26
6.2.1.1	<i>Watersheds, Water Balance and Peak Flows.....</i>	<i>26</i>
6.2.1.2	<i>Site Watercourses</i>	<i>29</i>
6.2.1.3	<i>Flow Measurements.....</i>	<i>32</i>
6.2.1.4	<i>Water Quality.....</i>	<i>32</i>
6.2.1.5	<i>Surface Water Use.....</i>	<i>33</i>
6.2.2	Water Supply Potential.....	33
6.2.3	Ground Water.....	33
6.3	Atmospheric Resources.....	45
6.3.1	General Climate and Weather Patterns	45
6.3.1.1	<i>Temperature and Precipitation Normals and Extremes.....</i>	<i>48</i>
6.3.2	Wind Normals and Extremes	49
6.3.3	Adverse Weather	53
6.3.4	Regional Ambient Air Quality	54
6.3.4.1	<i>Overview</i>	<i>54</i>
6.3.5	Ambient Air Quality Standards.....	55
6.3.6	Regional Air Quality Baseline.....	56
6.3.7	Ambient Noise (Terrestrial and Marine)	57
6.3.8	Ambient Light.....	59
6.4	Terrestrial Environment	59
6.4.1	Terrestrial Habitat and Vegetation.....	60
6.4.1.1	<i>Habitat Survey Results.....</i>	<i>61</i>
6.4.1.2	<i>Plant and Lichen Species of Conservation Concern (SOCC).....</i>	<i>65</i>
6.4.1.3	<i>Indications of Past Disturbance.....</i>	<i>66</i>
6.4.2	Wetlands.....	66
6.4.2.1	<i>Study Methods</i>	<i>66</i>
6.4.2.2	<i>Wetland Survey Results.....</i>	<i>67</i>
6.4.3	Terrestrial Wildlife	76
	<i>Important Terrestrial Fauna Habitats</i>	<i>76</i>
	<i>Vertebrates.....</i>	<i>80</i>
	<i>Invertebrates.....</i>	<i>91</i>
6.5	Freshwater Environment.....	92
6.5.1	Methodology	92
6.5.1.1	<i>Field Investigations.....</i>	<i>92</i>
6.5.1.2	<i>Habitat Assessment</i>	<i>94</i>
6.5.1.3	<i>Fish Collection.....</i>	<i>94</i>
6.5.1.4	<i>Water Quality.....</i>	<i>94</i>
6.5.2	Waterbodies and Watercourses	96

6.5.2.1	Fogherty Lake	96
6.5.2.2	Watercourses	96
6.5.3	Fish and Fish Habitat.....	97
6.5.4	Water Quality	98
6.5.4.1	Field Parameters	98
6.5.4.2	Conventional Parameters.....	98
6.5.4.3	Nutrients	98
6.5.4.4	Metals.....	99
6.6	Marine Environment	99
6.6.1	Physical Oceanography	99
6.6.1.1	Overview	99
6.6.1.2	Bathymetry	101
6.6.1.3	Hydrography.....	103
6.6.2	Marine Biology.....	112
6.6.2.1	Methodology.....	112
6.6.2.2	Results	118
	Marine Environment	118
6.6.2.3	Benthic Habitat and Communities.....	119
6.6.2.4	Marine Sediment Quality.....	119
6.6.2.5	Fish Community	119
6.6.2.6	Species at Risk.....	121
6.6.3	Ecological Summary.....	121
6.7	Species at Risk and Species of Conservation Concern.....	122
6.7.1	Terrestrial SAR and SOCC	123
6.7.1.1	Vascular Plant SAR and SOCC	123
6.7.1.1.1	Vascular Plant SAR and SOCC Potentially Occurring on the Black Point Site.....	124
6.7.1.1.2	Vascular Plant SAR and SOCC Confirmed to Occur on the Black Point Site.....	126
6.7.1.2	Lichen (Non-vascular Flora) SAR and SOCC.....	127
6.7.1.2.1	Lichen SAR and SOCC Potentially Occurring on the Black Point Site	127
6.7.1.2.2	Lichen SAR and SOCC Confirmed to Occur on the Black Point Site	129
6.7.1.3	Avifauna SAR and SOCC	131
6.7.1.3.1	Avifauna SAR and SOCC Potentially Occurring on the Black Point Site.....	131
6.7.1.3.2	Avifauna SAR and SOCC Confirmed to Occur on the Black Point Site.....	136
6.7.1.4	Mammal SARR and SOCC	139
6.7.1.4.1	Mammal SARR and SOCC Potentially Occurring on the Black Point Site	139
6.7.1.4.2	Mammal SOCC Confirmed to Occur on the Black Point Site	141
6.7.1.5	Herpetile SOCC.....	142
6.7.1.5.1	Herpetile Priority Species Potentially Occurring on the Black Point Site	142
6.7.1.6	Invertebrate SOCC - Odonates and Lepidopterans.....	143
6.7.1.6.1	Invertebrate Priority Species Potentially occurring on the Black Point Site	143
6.7.1.6.2	Invertebrate SOCC Confirmed to Occur on the Black Point Site.....	148
6.7.2	Freshwater SAR and SOCC.....	148
6.7.2.1	Freshwater Fish SAR and SOCC.....	148
6.7.2.1.1	Freshwater Fish SOCC Potentially Occurring on the Black Point Site	148
6.7.2.2	Freshwater Invertebrate SOCC.....	149
6.7.2.2.1	Freshwater Mussel SOCC Potentially Occurring on the Black Point Site.....	149
6.7.3	Marine SAR and SOCC	151
6.7.3.1	Marine Fish SOCC	151
6.7.3.1.1	Marine Fish SOCC Potentially Occurring on the Black Point Site	151
6.7.3.2	Marine Mammal SOCC.....	156
6.7.3.2.1	Marine Mammal SOCC Potentially Occurring at/near the Black Point Site	156
6.7.3.3	Marine Reptile SOCC.....	157
6.7.3.3.1	Marine Reptile SOCC Potentially Occurring on the Black Point Site.....	158
6.8	Socio-Economic Conditions	159

6.8.1	Nova Scotia Economic Outlook	159
6.8.2	Local Socio-Economic Conditions	159
6.8.2.1	Social Environment	159
6.8.2.2	Infrastructure and Services	163
6.8.2.3	Cultural Heritage	165
6.8.2.4	Economic Environment	165
6.8.3	First Nations Communities	169
6.8.3.1	Paqtnkek First Nation	171
6.8.3.2	Pictou Landing First Nation	171
6.8.3.3	Potolotek	171
6.8.3.4	Millbrook Band	172
6.8.3.5	Sipekne'katik First Nation	172
6.9	Land and Resource Use	173
6.9.1	Existing Land Use	173
6.9.2	Land Ownership and Tenure	173
6.9.3	First Nation Land and Resource Use	174
6.9.4	Protected Areas, Nature Reserves and Parks	175
6.9.5	Tourism and Recreation	175
6.9.6	Forestry and Agriculture	179
6.9.7	Mining	179
6.9.8	Water Use including Groundwater	179
6.10	Fisheries and Aquaculture	179
6.10.1	Regulatory Framework	179
6.10.2	Commercial Fishing in Nova Scotia	180
6.10.3	Overview of the Guysborough County Commercial Fishery	180
6.10.4	First Nations Fisheries	181
6.10.5	Species Harvested in the Project Area	183
6.10.6	Recreational Fisheries	191
6.10.7	Aquaculture	192
6.11	Shipping and Navigation	192
6.11.1	Overview of Commercial Shipping	192
6.11.2	Accessing Chedabucto Bay	194
6.11.3	Vessel Activity in Chedabucto Bay	196
6.11.4	Ballast Water Exchange and Pollution Prevention	196
6.12	Archeological Resources	198
6.12.1	Provincial	198
6.12.2	Black Point	198
6.12.3	Project Site	199

TABLE OF CONTENTS PART 3 (Section 7)

7.0 ENVIRONMENTAL EFFECTS ASSESSMENT.....	1
7.1 AIR QUALITY AND CLIMATE CHANGE	1
7.1.1 Overview	1
7.1.2 Boundaries.....	1
7.1.2.1 Temporal Boundaries	1
7.1.2.2 Spatial Boundaries	2
7.1.2.3 Administrative Boundaries	2
7.1.2.4 Technical Boundaries.....	2
7.1.3 Threshold for Determination of Significance.....	3
7.1.4 Effects of the Project on Air Quality.....	4
7.1.5 Mitigation & Monitoring.....	7
7.1.5.1 Mitigation.....	7
7.1.5.2 Monitoring.....	9
7.1.1 Residual Effects and Significance.....	12
7.2 NOISE AND VIBRATION	15
7.2.1 Overview	15
7.2.2 Boundaries.....	15
7.2.2.1 Temporal Boundaries	15
7.2.2.2 Spatial Boundaries	15
7.2.2.3 Administrative Boundaries	16
7.2.2.4 Technical Boundaries.....	16
7.2.3 Threshold for Determination of Significance.....	16
7.2.4 Effects of the Project on Noise.....	16
7.2.4.1 Project Construction Noise and Vibration Impacts.....	16
7.2.4.2 Project Operational Noise Impacts.....	17
7.2.4.3 Daytime and Evening Noise Impacts on Residences	19
7.2.4.4 Night-time Noise Impacts on Residences	19
7.2.4.5 Noise Impacts at Project Boundary.....	19
7.2.4.6 Blasting Noise and Vibration Impacts	20
7.2.5 Mitigation & Monitoring.....	20
7.2.5.1 Mitigation.....	20
7.2.5.2 Monitoring.....	21
7.3 AMBIENT LIGHT.....	25
7.3.1 Boundaries.....	25
7.3.1.1 Temporal Boundaries	25
7.3.1.2 Spatial Boundaries	25
7.3.1.3 Technical Boundaries.....	25
7.3.1.4 Administrative Boundaries	25
7.3.2 Threshold for Determination of Significance.....	26
7.3.3 Effects of the Project of Ambient Light.....	26
7.3.3.1 Construction	26
7.3.3.2 Operation.....	27
7.3.3.3 Decommissioning.....	29
7.3.4 Mitigation and Monitoring	29
7.3.4.1 General Mitigation	29
7.3.5 Site Specific Mitigation.....	30
7.3.5.1 Monitoring.....	30

	7.3.6 Residual Effects and Significance.....	31
7.4	GEOLOGY, SOIL AND SEDIMENT QUALITY	34
	7.4.1 Overview	34
	7.4.2 Boundaries.....	34
	7.4.2.1 Temporal Boundaries	34
	7.4.2.2 Spatial Boundaries	34
	7.4.2.3 Administrative Boundaries	34
	7.4.2.4 Technical Boundaries.....	34
	7.4.3 Threshold for Determination of Significance.....	35
	7.4.4 Effects of the Project on Geology, Soil and Sediment Quality.....	35
	7.4.5 Mitigation & Monitoring.....	36
	7.4.5.1 Mitigation	36
	7.4.5.2 Monitoring.....	37
	7.4.6 Residual Effects & Significance	37
7.5	GROUNDWATER RESOURCES	40
	7.5.1 Groundwater Resources	40
	7.5.2 Summary of Conceptual Hydrogeologic Model.....	40
	7.5.3 Boundaries.....	41
	7.5.3.1 Temporal Boundaries	41
	7.5.3.2 Spatial Boundaries	41
	7.5.3.3 Administrative Boundaries	42
	7.5.3.4 Technical Boundaries.....	42
	7.5.4 Threshold for Determination of Significance.....	42
	7.5.5 Effects on Groundwater	43
	7.5.6 Mitigation & Monitoring.....	44
	7.5.6.1 Mitigation	44
	7.5.6.2 Monitoring.....	45
	7.5.7 Residual Effects and Significance.....	46
7.6	MARINE AND SURFACE WATER RESOURCES.....	48
	7.6.1 Overview	48
	7.6.2 Boundaries.....	48
	7.6.2.1 Temporal Boundaries	48
	7.6.2.2 Spatial Boundaries	48
	7.6.2.3 Administrative Boundaries	48
	7.6.2.4 Technical Boundaries.....	49
	7.6.3 Threshold for Determination of Significance.....	49
	7.6.4 Effects on Surface Water Resources	50
	7.6.5 Mitigation & Monitoring.....	52
	7.6.6 Retention Ponds	53
	7.6.7 Fuel and Chemical Storage.....	54
	7.6.8 Monitoring.....	54
	7.6.9 Residual Effects & Significance	54
7.7	TERRESTRIAL ECOSYSTEMS, HABITAT AND VEGETATION	58
	7.7.1 Boundaries.....	58
	7.7.2 Threshold for Determination of Significance.....	58
	7.7.3 Effects on Terrestrial Habitat and Vegetation.....	58
	7.7.3.1 Construction	58
	7.7.3.2 Operation.....	60
	7.7.3.3 Decommissioning.....	60

7.7.4	Mitigation & Monitoring	61
7.7.5	Residual Effects & Significance	62
7.8	WETLANDS	65
7.8.1	Boundaries	65
7.8.2	Threshold for Determination of Significance	65
7.8.3	Effects on Wetlands	65
7.8.3.1	Construction	67
7.8.3.2	Operation	69
7.8.3.3	Decommissioning	70
7.8.4	Mitigation and Monitoring	70
7.8.5	Residual Effects & Significance	71
7.9	TERRESTRIAL WILDLIFE	74
7.9.1	Boundaries	74
7.9.2	Threshold for Determination of Significance	74
7.9.3	Effects on Birds and Other Terrestrial Fauna	75
7.9.3.1	Construction	75
7.9.3.2	Operation	77
7.9.3.3	Decommissioning	79
7.9.4	Mitigation & Monitoring	79
7.9.5	Residual Effects & Significance	82
7.10	FRESHWATER SPECIES AND HABITATS	87
7.10.1	Effects Mechanics	87
7.10.2	Boundaries	88
7.10.2.1	Temporal Boundaries	88
7.10.2.2	Spatial Boundaries	88
7.10.2.3	Relevant Legislation	88
7.10.2.4	Technical Boundaries	88
7.10.3	Threshold for Determination of Significance	88
7.10.4	Effects on Freshwater Environment	89
7.10.5	Mitigation and Monitoring	93
7.10.5.1	Mitigation	93
7.10.5.2	Monitoring	94
7.10.6	Methodology for Determination of Significance	94
7.10.7	Residual Effects and Significance	94
7.11	MARINE SPECIES AND HABITATS	98
7.11.1	Overview	98
7.11.2	Boundaries	98
7.11.2.1	Temporal Boundaries	98
7.11.2.2	Spatial Boundaries	99
7.11.2.3	Administrative Boundaries	99
7.11.2.4	Technical Boundaries	99
7.11.3	Threshold for Determination of Significance	99
7.11.4	Effects on Marine Environment	100
7.11.5	Mitigation and Monitoring	106
7.11.6	Offset Strategies	108
7.11.7	Methodology for Determination of Significance	109
7.11.8	Residual Effects and Significance	109
7.12	SAR and SOCC	112
7.12.1	Boundaries	112

7.12.2	Threshold for Determination of Significance	112
7.12.3	Effects on Terrestrial Flora SAR/SOCC	112
7.12.4	Effects on Terrestrial Fauna SAR/SOCC.....	119
7.12.4.1	Mammals.....	119
7.12.4.2	Birds	121
7.12.4.3	Herpetiles	122
7.12.4.4	Invertebrates	122
7.12.5	Effects on Freshwater Flora and Fauna SAR/SOCC	122
7.12.6	Effects on Marine Fauna SAR/SOCC.....	122
7.12.7	Mitigation & Monitoring.....	122
7.12.7.1	Terrestrial SAR/ SOCC	123
7.12.7.2	Terrestrial Fauna SAR/SOCC	123
7.12.7.3	Freshwater SAR/SOCC	125
7.12.7.4	Marine SAR/SOCC.....	125
7.12.8	Summary and Residual Effects	125
7.13	LOCAL ECONOMY, LAND AND RESOURCE USE	131
7.13.1	Overview	131
7.13.2	Boundaries.....	131
7.13.2.1	Temporal Boundaries.....	131
7.13.2.2	Spatial Boundaries	131
7.13.2.3	Administrative Boundaries	132
7.13.2.4	Technical Boundaries.....	132
7.13.3	Threshold for Determination of Significance	132
7.13.4	Effects on Local Economy, Land and Resource Use.....	132
7.13.5	Mitigation and Monitoring.....	134
7.13.5.1	Mitigation.....	134
7.13.5.2	Monitoring.....	135
7.13.6	Residual Effects and Significance.....	135
7.14	TOURISM AND RECREATION	138
7.14.1	Overview	138
7.14.2	Boundaries.....	138
7.14.2.1	Temporal Boundaries.....	138
7.14.2.2	Spatial Boundaries	138
7.14.2.3	Administrative Boundaries	138
7.14.2.4	Technical Boundaries.....	138
7.14.3	Threshold for Determination of Significance	138
7.14.4	Project Effects on Tourism and Recreation.....	139
7.14.5	Mitigation & Monitoring.....	140
7.14.6	Residual Effects & Significance	140
7.15	COMMERCIAL FISHERIES	143
7.15.1	Overview	143
7.15.2	Boundaries.....	143
7.15.2.1	Temporal Boundaries.....	143
7.15.2.2	Spatial Boundaries	143
7.15.2.3	Administrative Boundaries	144
7.15.2.4	Technical Boundaries.....	144
7.15.3	Threshold for Determination of Significance	144
7.15.4	Effects of the Project on Commercial Fisheries.....	144
7.15.5	Mitigation & Monitoring.....	146

7.15.5.1	Mitigation.....	146
7.15.5.2	Monitoring.....	147
7.15.6	Residual Effects & Significance	148
7.16	ARCHAEOLOGICAL AND HERITAGE RESOURCES	151
7.16.1	Boundaries.....	151
7.16.1.1	Temporal Boundaries.....	151
7.16.1.2	Spatial Boundaries	151
7.16.1.3	Technical Boundaries.....	151
7.16.1.4	Administrative Boundaries	152
7.16.2	Threshold for Determination of Significance	152
7.16.3	Effects Archaeological and Heritage Resources.....	152
7.16.3.1	Construction	152
7.16.3.2	Operation.....	152
7.16.3.3	Decommissioning.....	152
7.16.4	Mitigation and Monitoring.....	152
7.16.4.1	Mitigation.....	152
7.16.4.2	Monitoring.....	153
7.16.5	Residual Effects and Significance.....	153
7.17	ABORIGINAL LAND AND RESOURCE USE	155
7.17.1	Boundaries.....	157
7.17.2	Threshold for Determination of Significance	157
7.17.3	Effects on Aboriginal Land and Resource Use	157
7.17.4	Residual Effects and Significance.....	161
7.18	CHANGES TO COMPONENTS WITHIN FEDERAL JURISDICTION.....	162
7.18.1	Environmental Effects Within Federal Jurisdiction	162
7.18.2	Power and Duty by Federal Authority.....	163
7.18.3	Changes Expected on Federal or Transboundary Lands	164
7.18.4	Effects of Changes to the Environment.....	165
7.19	ACCIDENT AND MALFUNCTION SCENARIOS.....	171
7.19.1	Hazard Identification	171
7.19.2	Structural Failures.....	173
7.19.3	Accidents.....	176
7.19.4	Other.....	183
7.19.5	Risk Assessment.....	184
7.19.6	Conclusion.....	187

TABLE OF CONTENTS PART 4 (Sections 8-15)

8.0	EFFECTS OF THE ENVIRONMENT ON THE PROJECT	3
8.1	Potential Effects of Drought or Flooding	3
8.2	Potential Effects of Extreme Temperatures	4
8.3	Potential Effects from Storms	5
8.4	Potential Effects of Extreme Marine Conditions	7
8.5	Seismic Activity	8
8.6	Implications of Climate Change Trends	8
8.7	Conclusion	13
9.0	CUMULATIVE ENVIRONMENTAL EFFECTS	13
9.1	Project Identification	13
	<i>9.1.1 Planned and Reasonably Certain</i>	<i>14</i>
	<i>9.1.2 Announced and Uncertain</i>	<i>14</i>
9.2	Cumulative Assessment Methodology	15
9.3	Spatial and Temporal Boundaries	15
9.4	Cumulative Effects Assessment	15
	<i>9.4.1 Projects Retained</i>	<i>15</i>
	<i>9.4.2 Interacting or Overlapping VCs</i>	<i>16</i>
	<i>9.4.3 Mitigation Measures</i>	<i>16</i>
	<i>9.4.4 Residual Cumulative Effects and Significance</i>	<i>17</i>
10.0	PROPOSED COMPLIANCE AND EFFECTS MONITORING PROGRAMS	17
11.0	CONSULTATION AND ENGAGEMENT	43
11.1	Consultation Strategy and Objectives	43
11.2	Public and Agency Consultation	43
11.3	Website	44
11.4	Stakeholder Database and Mailing List	44
11.5	Public Information Sessions/Open Houses	46
11.6	Interviews	47
11.7	Newsletters	47
11.8	Community Liaison Committee	48
11.9	Government and Agency Consultation	49
11.10	Other Group Meetings	49
11.11	Engagement of Aboriginal Communities	56
11.12	Strategy and Objectives	56
11.13	Engagement Strategy and Activities	57
11.14	Identified Issues and Concerns	59
11.15	Memorandum of Understanding (MOU)	59
11.16	Engagement Following EIS Submission	60
11.17	Issues Identified by Other Stakeholders	60
11.18	Consultation Following EIS Submission	69
12.0	ENVIRONMENTAL IMPACT STATEMENT CONCLUSIONS	70
12.1	Effects of the Project on the Environment	70
12.2	Effects of the Environment on the Project	71
12.3	Cumulative Effects	71
12.4	Conclusions of the Proponent	72

APPENDICES

Volume 2

Appendix A: Hydrogeological Technical Study

Appendix B: Erdene Acid Rock Drainage (ARD) Report

Appendix C: Surface Water Assessment Technical Report

Appendix D: Noise and Vibration Technical Report

Appendix E: AMEC 2010 and 2014 Ecological Surveys

Volume 3

Appendix F: Wetland Baseline Survey Report

Appendix G: AECOM 2011 Winter Bird Survey

Appendix H: 2014 Fall Moose Survey

Appendix I: Freshwater Habitat Assessment Supporting Documentation

Appendix J: Marine Habitat Assessment Supporting Documentation

Appendix K: Mi'kmaq Ecological Knowledge Study

Appendix L: 2011 and 2014 Archaeological Resource Assessments

Appendix M: Consultation and Engagement References

Appendix N: Species at Risk Supporting Documentation

Appendix O: Air Quality Technical Report

Table of Concordance

Between the
CEAA Guidelines (June 2014) for the Black Point Quarry Project
and the
Black Point Quarry Project Environmental Impact Statement

Black Point Quarry Project
Guysborough County, NS

February, 2015

Table of Concordance: CEAA EIS Guidelines and Black Point Quarry Project EIS Report		
CEAA EIS Guidelines		Black Point Quarry Project EIS Report
Section	Title	Title
1.0	Introduction	1.0 Project Introduction
2.0	Guiding Principles	N/A
2.1	Environmental Assessment As A Planning Tool	N/A
2.2	Public Participation	11.0 Consultation and Engagement
2.3	Aboriginal Consultation	11.11 Engagment of Aboriginal Communities
3.0	Preperation and Presentation Of The EIS	N/A
3.1	Agency Guidance	11.9 Government and Agency Consultation
3.2	Study Strategy and Methodology	5.0 Environmental Effects Assessment Methodology
3.3	Intergration of EA, Aboriginal and Public Consultation Information	11.0 Consultation and Engagement
3.4	Use of Information	N/A
3.4.1	Scientific Advice	11.9 Government and Agency Consultation
3.4.2	Community Knowledge and Aboriginal Traditional Knowledge	11.11 Engagment of Aboriginal Communities; App. K MEKS Study
3.4.3	Existing Information	6.0 Existing Conditions
3.4.4	Confidential Information	11.9 Government and Agency Consultation
3.5	Presentation and Organization of the EIS	1.1 Report Organisation
4.0	Summary of Environmental Impact Statement	Summary Report
5.0	Introduction and Project Overview	1.0 Project Introduction; 13 Project Overview
5.1	Geographical Setting	1.4 Geographical Setting
5.2	Regulatory Framework and the Role of the Government	2.0 Regulatory Framework
5.3	Participants in the Environmental Assessment	1.6 Participants In the Assessment
5.4	The Proponent	1.6.1 The Proponent
5.5	Purpose of the Project	1.8 Purpose of The Project
5.6	Project Components	3.1 Overview Of Project Components and Site Layout
5.7	Project Activities	3.2 Construction Phase; 3.3 Operations Phase; 3.4 Decommissioning Phase
6.0	Scope of the Project	5.1 Overview
7.0	Scope of Assessment	5.0 Environmental Effects Assessment Methodology
7.1	Factors To Be Considered	2.0 Regulatory Framework; 5.0 Environmental Effects Assessment Methodology; 7.18 Changes to the Enviornment Within Federal Jurisdiction
7.1.1	Valued Components	5.3 Valued Components Selection to 5.13 Description of Retained VCs
7.1.2	Effects of Potential Accidents or Malfunctions	3.5 Accidents and Malfunctions; 7.19 Accident and Malfunction Scenarios
7.1.3	Effects of the Environment On The Project	8.0 Effects Of The Environment On The Project
7.2	Scope of the Factors	5.0 Environmental Effects Assessment Methodology; 7.18 Changes to the Enviornment Within Federal Jurisdiction
7.2.1	Spatial Boundaries	5.5.2 Spatial Boundaries
7.2.2	Temporal Boundaries	5.5.1 Temporal Boundaries
8.0	Alternative Means of Carrying Out The Project	4.0 Alternatives To The Project
9.0	Baseline Conditions	6.0 Existing Conditons
9.1	Existing Environment	6.0 Existing Conditions
9.1.1	Methodology	6.0 Existing Conditions
9.1.2	Biophysical Environment	6.1 to 6.7 Existing Conditions
9.1.3	Human Environment	6.8 to 6.12 Existing Conditions
9.2	Potential Or Established Aboriginal and Treaty Rights and Related Interests	6.8.3 First Nation Communitéis; 6.10.4 First Nation Fisheries; 11.11 Engagement Of The Aboriginal Communities
10.0	Effects Assessment	N/A
10.1	Environmental Effects	7.0 Environmental Effects Assessment

CEAA EIS Guidelines		Black Point Quarry Project EIS Report
Section	Title	Title
10.1.1	Methodology	5.0 Environmental Effects Assessment Methodology; 7.0 Environmental Effects Assessment
10.1.2	Changes to the Environment	7.18 Changes to the Environment Within Federal Jurisdiction
10.1.3	Effects of Changes to the Environment	7.18 Changes to the Environment Within Federal Jurisdiction
10.2	Adverse Impacts on Aboriginal and Treaty Rights and Related Interests	7.17 Aboriginal Land And Resource Use; 11.11 Engagement of Aboriginal Communities
10.3	Public Concerns	11.0 Consultation and Engagement Programs; 11.14 Identified Issues and Concerns; Tables 11-7, 11-8 and 11-12 Issues And Concerns; Table 10-3 Issues Raised
11.0	Mitigation	
11.1	Environmental Mitigation	7.0 Environmental Effects Assessment; Table 10.1 Proposed Mitigation and Monitoring by VC
11.1.1	Methodology	3.5.5 Health, Safety and Environmental Management; 7.0 Environmental Effects Assessment; Table 10.1 Proposed Mitigation and Monitoring by VC
11.1.2	Summary of Environmental Mitigation	Table 7.18-1 Summary of Environmental Mitigation
11.2	Measures to Address Impacts on Aboriginal Rights	7.17 Aboriginal Land and Resource Use
11.3	Measures to Address Public Concerns	11.0 Consultation and Engagement Programs; Table 10-3 Issues Raised During the Assessment and Proponent Commitments

1.0 INTRODUCTION AND ENVIRONMENTAL ASSESSMENT CONTEXT

Vulcan Materials Company (Vulcan), a U.S.-based aggregate producer and Morien Resources Corporation (Morien), a Nova Scotia-based resource development company, have jointly prepared this Environmental Impact Statement (EIS), which outlines the proposed development, operation, and decommissioning and abandonment of a hard rock quarry and marine terminal at Black Point in Guysborough County, Nova Scotia (**Figure 1**). **Black Point Aggregates Inc.**, a wholly owned subsidiary of Vulcan Materials Company, is the named Proponent of the Project. Following the environmental assessment process, Black Point Aggregates Inc. will develop and operate the quarry and marine terminal.

This Environmental Impact Statement (EIS) has been prepared to obtain approval pursuant to the federal *Canadian Environmental Assessment Act, 2012* (CEAA, 2012) and, at the same time, approval for a Class I undertaking pursuant to the provincial *Environmental Assessment Regulations* made under the *Nova Scotia Environment Act*.

The EIS has been prepared to respond to Project-specific *Guidelines for the Preparation of an Environmental Impact Statement* pursuant to CEAA, 2012 and the Nova Scotia Registration Document pursuant to the Nova Scotia Environment Act, which were developed for the Project by the Canadian Environmental Assessment Agency (CEA Agency) and Nova Scotia Environment (NSE) with input from other government departments and agencies and the public.

Project: Black Point Quarry Project

Proponent: Black Point Aggregates Inc.

2.0 PROJECT OVERVIEW

The Black Point Quarry Project property has a total surface area of 354.5 ha of which the finished quarry will occupy approximately 180 ha while the processing plant, administration and stockpile areas together will occupy approximately 28 ha. Rock reserves in the proposed quarry are estimated at more than 400 million metric tonnes (MT).

Rock will be quarried using industry standard drilling and blasting procedures from the granite reserve creating a quarry pit that will expand in depth and size over the 50+ year lifetime of the mine. As mining progresses a series of rock benches will be created in the quarry pit for safety reasons. Quarried rock will be crushed, screened, washed and stockpiled on site, then offloaded

via a deep water marine terminal into Panamax-sized bulk carrier ships for transport to markets along the eastern and Gulf coast markets of the United States

The anticipated average annual production rate will exceed 1.0 MT with a peak production rate of 7.5 MT per year, which is roughly 5.0 MT of product sales should market conditions support that sales volume. The Project is anticipated to have capital costs on the order of US\$80-\$110 million and will be a significant employer in Guysborough County throughout its expected 50+ year lifespan. No public funding is currently being sought for this Project.

2.1 Project Need and Justification

The purpose of the Black Point Quarry Project is to supply construction aggregate to markets predominantly on the eastern and Gulf coasts of the United States and possibly to markets in eastern and central Canada. Although construction aggregates have numerous end uses, their general application is in the production of building materials such as concrete and asphalt.

While materials used to produce construction aggregates are relatively abundant, these resources must be located in areas that are geographically accessible. In addition, the rights and permits to recover the resources must be obtainable, and there must be sufficient market capacity to support the planned production of the mining operation. Finally, aggregates must meet strict quality requirements related to the chemical and physical characteristics of the rock. Most rocks do not meet these geographic conditions and quality specifications and cannot qualify as viable construction aggregate resources.

In the U.S. market, the majority (80% or more) of aggregates are transported by truck from the quarry to the consumer. This form of transport is expensive and limits the typical aggregate operation to a market radius of about 80 km from the quarry. The south eastern U.S. aggregate market is a prime target for bulk vessel transported aggregate due in part to the geologic absence of suitable aggregate resources in coastal areas.

The revenue generated from the Project will provide economic benefit to the people and governments of Guysborough County and Nova Scotia through direct and indirect employment, royalties and taxes paid, dollars invested into goods and services directly by the Project Proponent, and indirect dollars that will go into local businesses and services from employees and contractors working on the Project and at the quarry.

2.2 Project Location

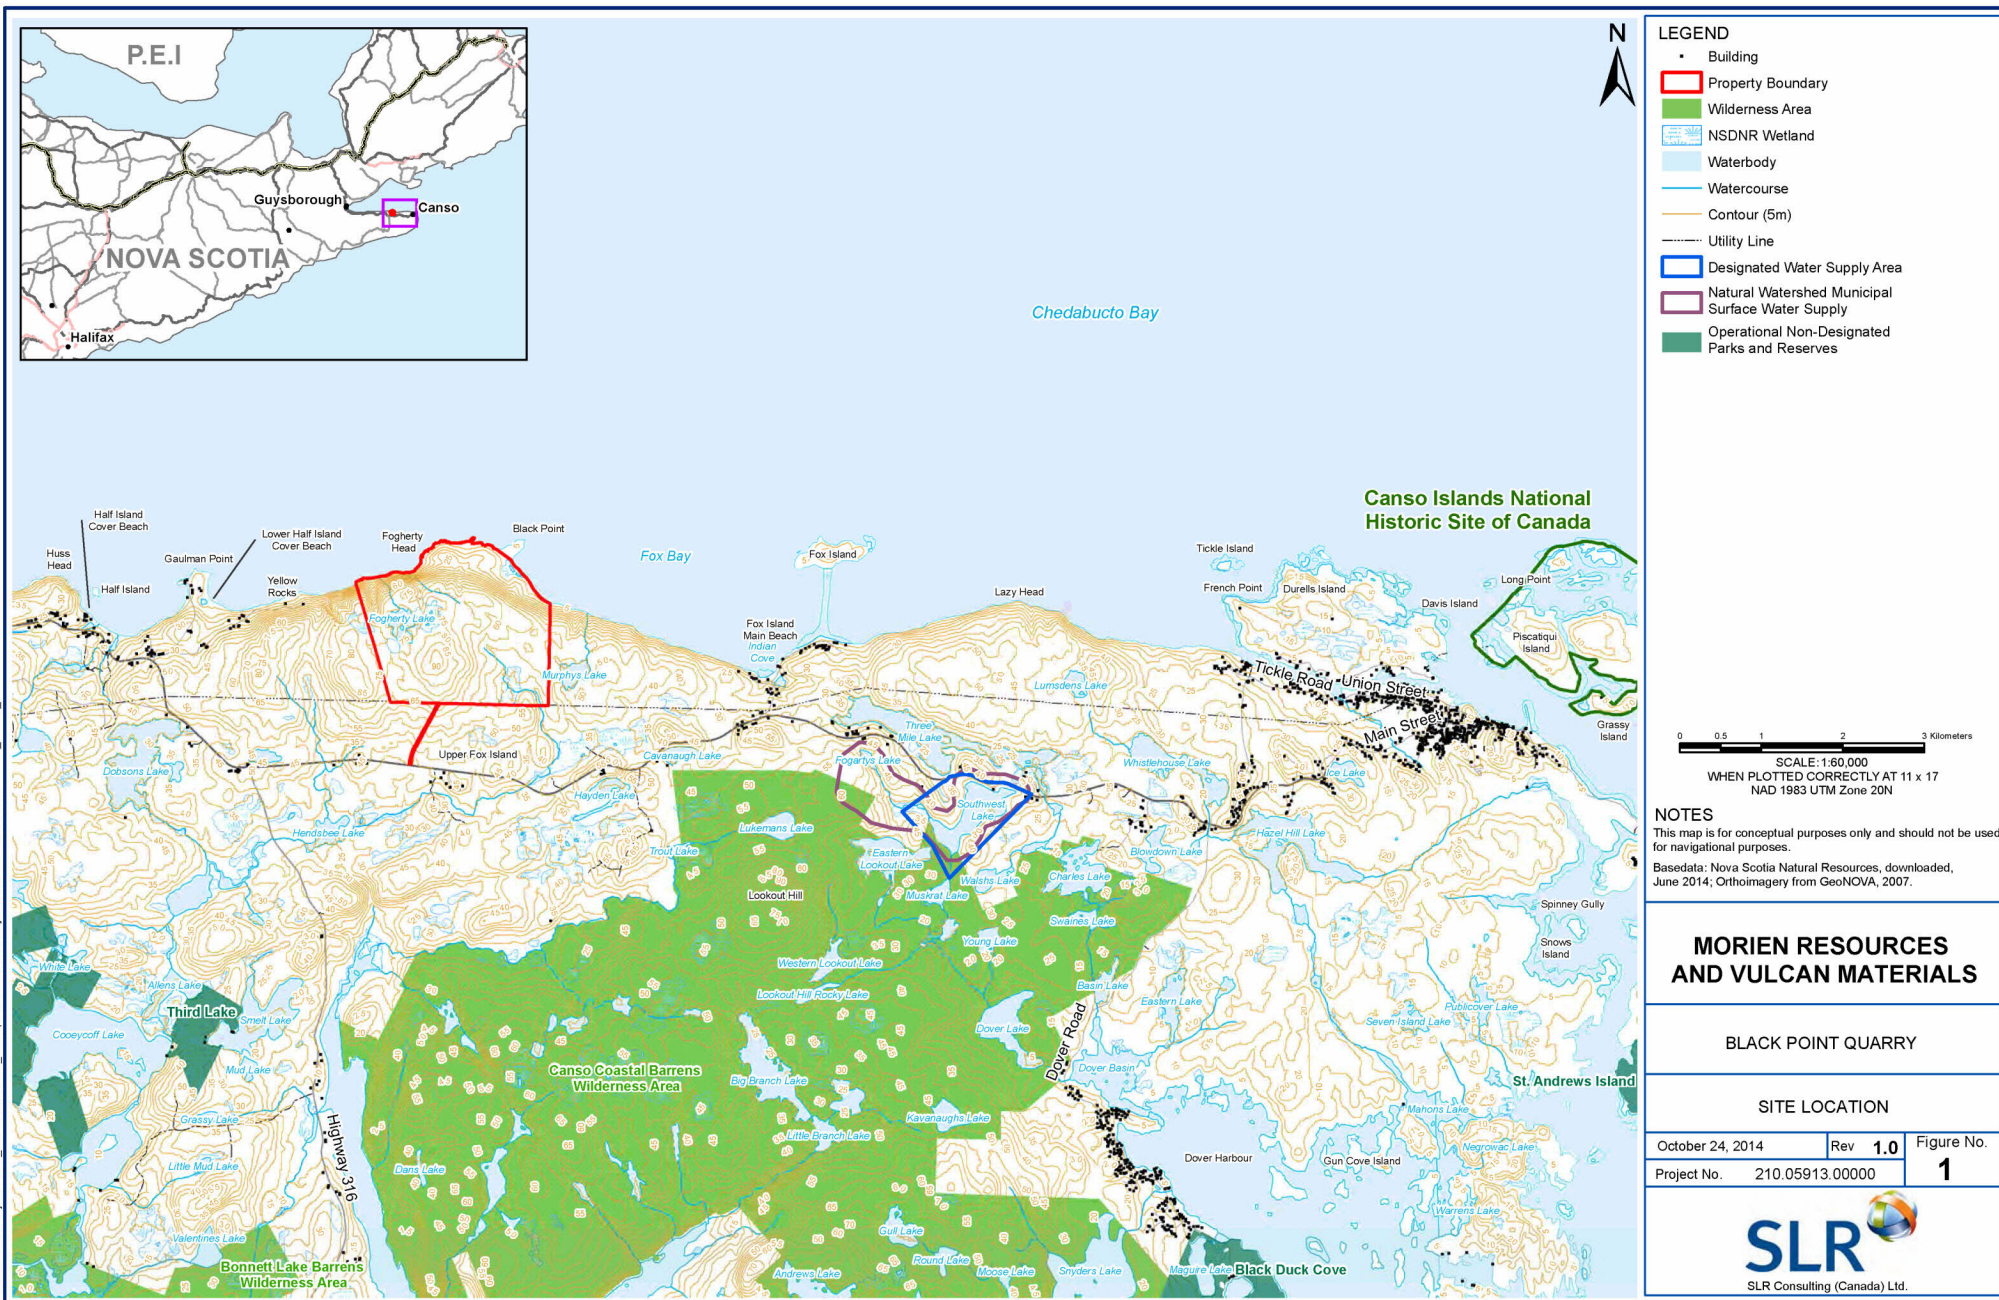

The lands to be developed are owned by the Municipality of the District of Guysborough (MODG) and will be leased to the Proponent. The approximate center of the Project site is located at:

45°21'13.25"N

61°08'56.15"W

The generalized property boundaries are shown on **Figures 1 and 2**. Table 1 provides coordinates for the four corners of the Property and the submerged Crown Land Lease, currently being reviewed by the province that will host the marine terminal.

2.3 Project Components

The primary components associated with the Project include:

1. An unpaved access road from provincial Route 16 into the quarry;
2. The quarry and primary crushing area;
3. The processing (finishing) plant consisting of secondary and tertiary processing (crushing and washing) and a stockpile laydown area;
4. Modular buildings that comprise the administration complex; and,
5. A 160 m long marine terminal and load-out facility.

The locations of the primary project components are depicted in **Figure 3**.

2.3.1 Access Road

A single private unpaved access road to the quarry, processing plant and marine terminal will be constructed prior to mining. The access road will be 10 m wide and proceed north from Route 16 to the southern property boundary, a distance of approximately 800 m. From the southern property boundary, the road will be extended easterly and northerly approximately 2.5 km to access the processing area and marine terminal.

2.3.2 Open Pit Quarry and Primary Crusher

The final quarry footprint will comprise approximately 180 ha (**Figure 3**). The quarry will be developed initially in a westerly direction before proceeding in a southerly direction and to a grade at or near elevation -30 m asl (i.e., 30 m below sea level).

Benches will generally be 15 m in height, although during the initial development phases, face heights could be less. Safety benches will be established every two benches and will have a width of approximately 7.5 m. The final slopes for the quarry will have face angles of 85 degrees with a maximum pit slope of 65 degrees. Working benches will have face angles of 70 to 75 degrees.

Freshly mined rock will be transported to and reduced in size by a primary crusher located on a bench on the east side of the quarry. The crushed material will then be transported via conveyor to the processing plant.

2.3.3 Processing Plant

The processing plant site is approximately 28 ha and will be located in the northern section of the Project site along Chedabucto Bay as shown on **Figure 3**. This area will be used for secondary and tertiary crushing, screening, washing and conveying, as well as stockpiling aggregate products, equipment, fuel and material storage, ship loading and administrative buildings.

The area will contain two ponds beginning in Phase 3 (development phases are described below), located on the western edge of the plant site against the cliff. Each pond will be sized to hold approximately 6,100 m³. One of the ponds will be dedicated to stormwater retention and the other for process water. During Phase 1, temporary ponds will be utilized as required to manage stormwater. In Phase 2, one of the permanent ponds will be constructed and dedicated to stormwater retention.

This portion of the site will also include two surge piles, various aggregate product piles (fractionated, screenings and base material) and approximately 1,000,000 tons of product ready for shipment.

Based upon the preliminary design, there will be five phases of the processing plant ranging from an initial portable circuit utilized for site development to a large fixed plant capable of producing an anticipated peak production of 7.5 MT and producing 5.0 MT of saleable product. Plant development phases are shown on **Figure 4** to **Figure 8**.

Phase 1

A small portable plant with a capacity up to 1,000 tonnes per hour (TPH) will be utilized for initial site development. The plant will consist of two portable track-mounted crushing plants that include vibrating feeders and a number of conveyors. The plant will be used to produce a coarse fill material for site development needs. Power for the plant will be provided by diesel powered generators.

Phase 2

In the second phase plant, two additional track mounted crushing modules will be added to the Phase 1 equipment. This plant will produce a fine graded fill material for final site development needs. Power for this plant will be provided by diesel powered generators built into the track mounted crushing units.

Phase 3

Major components of Phase 3 include the Phase 2 equipment described above, two additional portable track-mounted screening plants and one track mounted tertiary crushing plant with a belt feeder and conveyors.

These additional mobile units will be used to begin production to meet the initial aggregate sales demand. Power for the additional units will utilize diesel powered generators with combined capacity of 260 kW in addition to the existing generators identified in Phases 1 and 2. Production during Phase 3 is expected to be approximately 500 TPH.

Marine terminal construction (see below) is expected to begin during Phase 3.

Phase 4

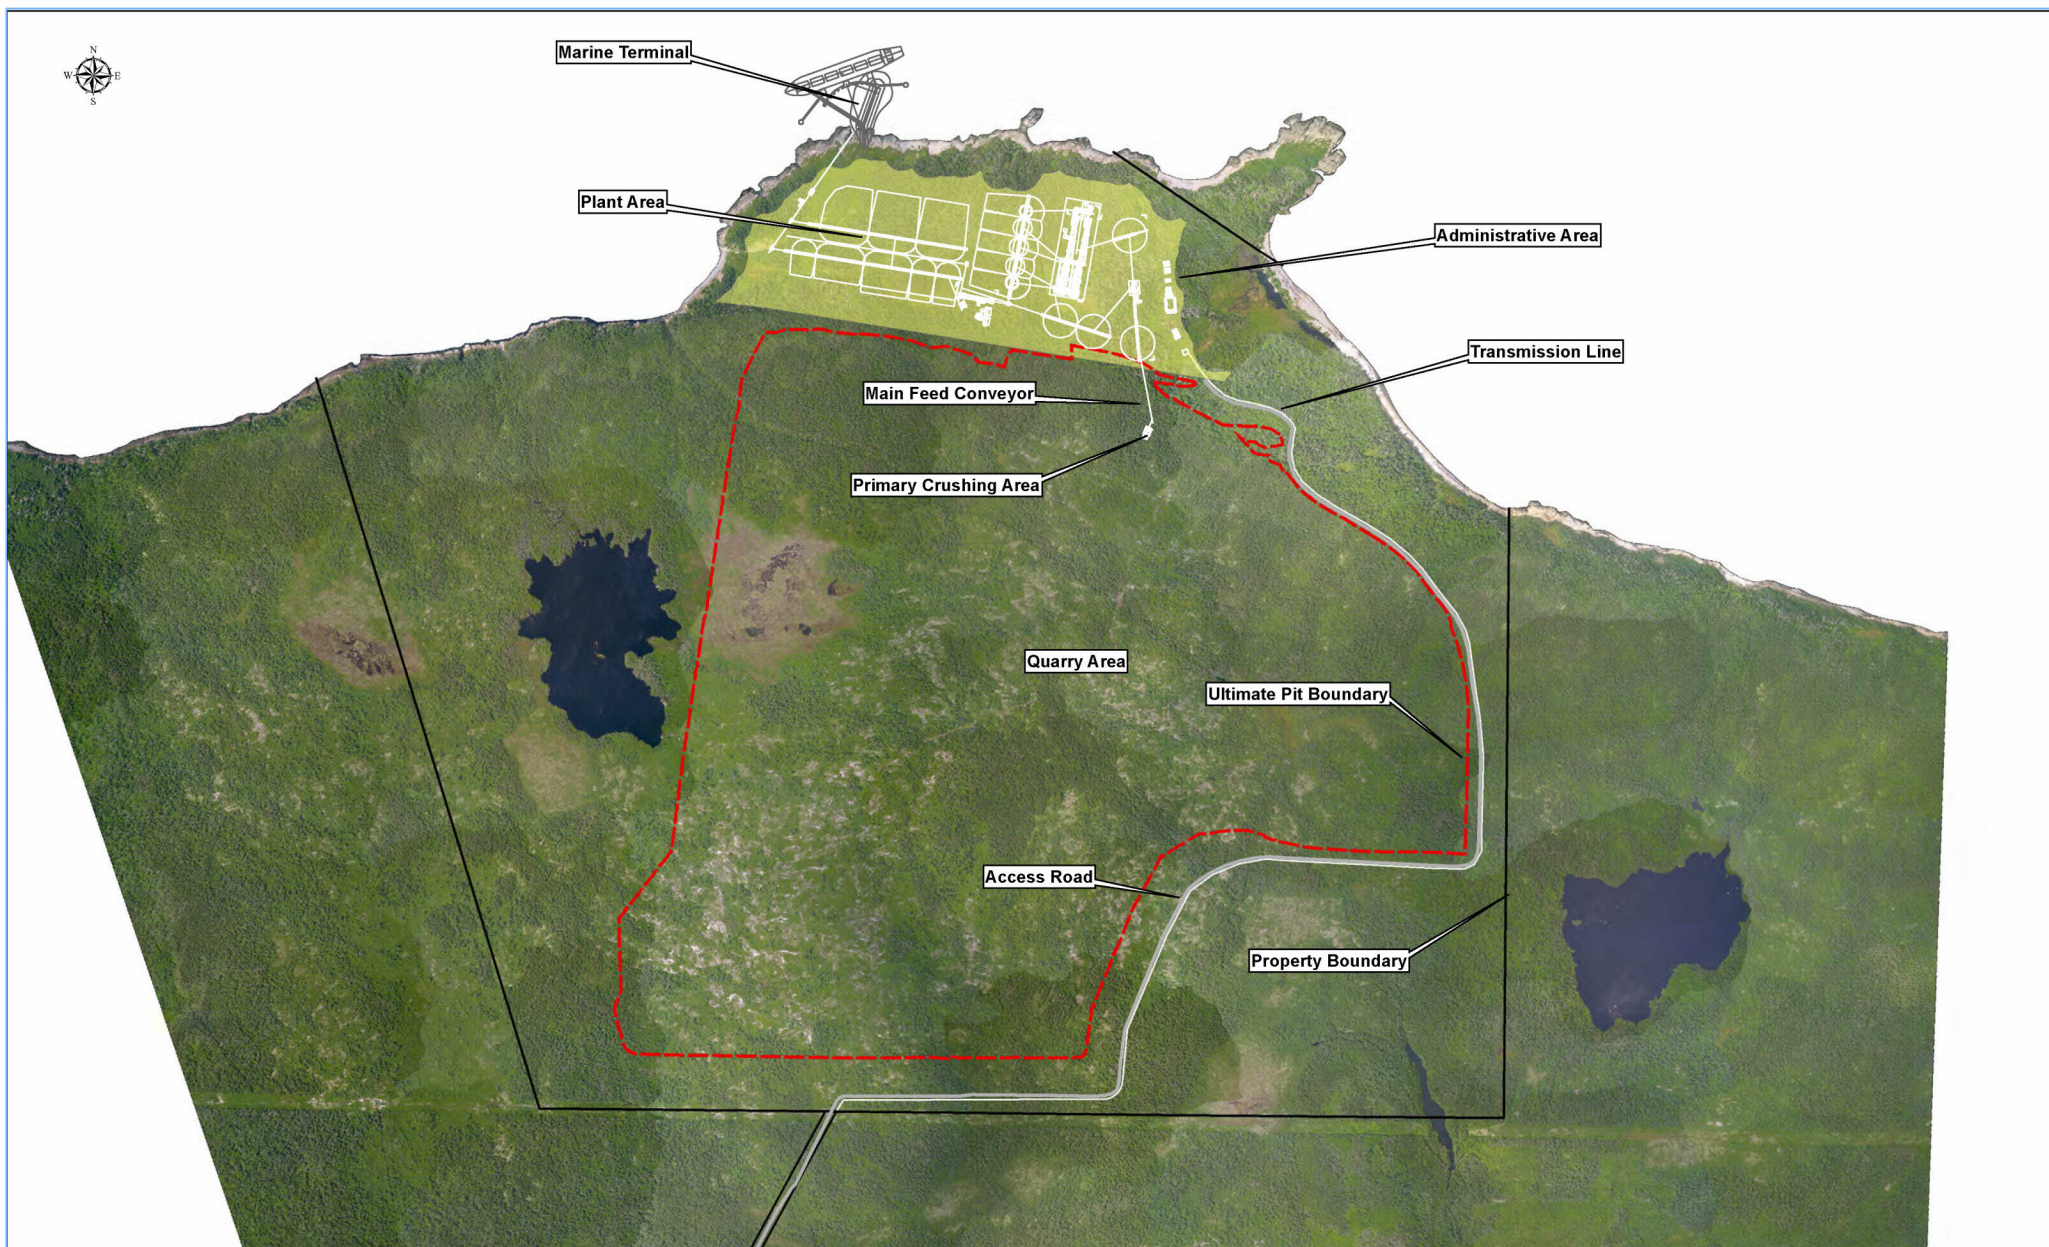

When the sales demand dictates a higher production rate, the mobile plant will be replaced by a fixed plant. The plant will have a flexible design that will allow it to be expanded as the market demand increases. The initial fixed plant will have the capability to produce up to 1,400 TPH through the tertiary plant. Electrical power for the plant will be provided via Nova Scotia Power Inc.

Phase 5

As the sales demand increases and production rates approach the limit of the initial fixed plant, the final phase will be initiated. This plant will upgrade the tertiary portion of the Phase 4 plant by installing a parallel, identical tertiary processing circuit. Production through the finishing plant will be increased to 2,800 TPH.

2.3.4 Administrative Buildings

Approximately 2.5 ha will be dedicated for an administrative area located on the eastern edge of the plant site (**Figure 8**). In this area, two buildings (modular or fixed) will be erected. One will contain offices and the administrative functions while the other will contain facilities for on-site workers such as a locker/shower room, washroom, first aid station, lunchroom, quality control laboratory and shop. This area will also include a site to store fuel and other maintenance fluids. Mobile equipment will be parked adjacent to the shop.

2.3.5 Marine Terminal

A rubble mound with conveyors and related infrastructure installed on a stone breakwater constructed of coarse rock will be built as the marine terminal. Caissons and mooring dolphins will be used for berthing the ship. Preliminary engineering drawings for the terminal are shown in **Figure 9 to Figure 12**. The major components of the terminal are:

- Three breasting caissons used for berthing the ship.
- Two mooring dolphins.
- Eleven slewing rail piers that support the slewing rail, which in turn allows the shiploader to move in an arc.
- One slewing rail caisson to support the slewing rail.
- Shiploader pivot point caisson, which provides the lateral stability of the shiploader.
- Rubble fill with an access road for maintenance.
- The shiploader arm that delivers aggregate product to the ship.

The shiploader is a telescoping system approximately 136 m long when fully extended. It will have a loading capacity approaching 5,000 TPH. The rubble mound portion of the terminal will be approximately 160 m in length. It will be constructed with a clean rock-filled base, armour stone protection on all sides and include a crushed stone surface. This structure will have a seafloor footprint of approximately 11,078 m² which includes the combined seafloor surface area occupied by the rubble fill, caissons and dolphins.

2.4 Project Activities

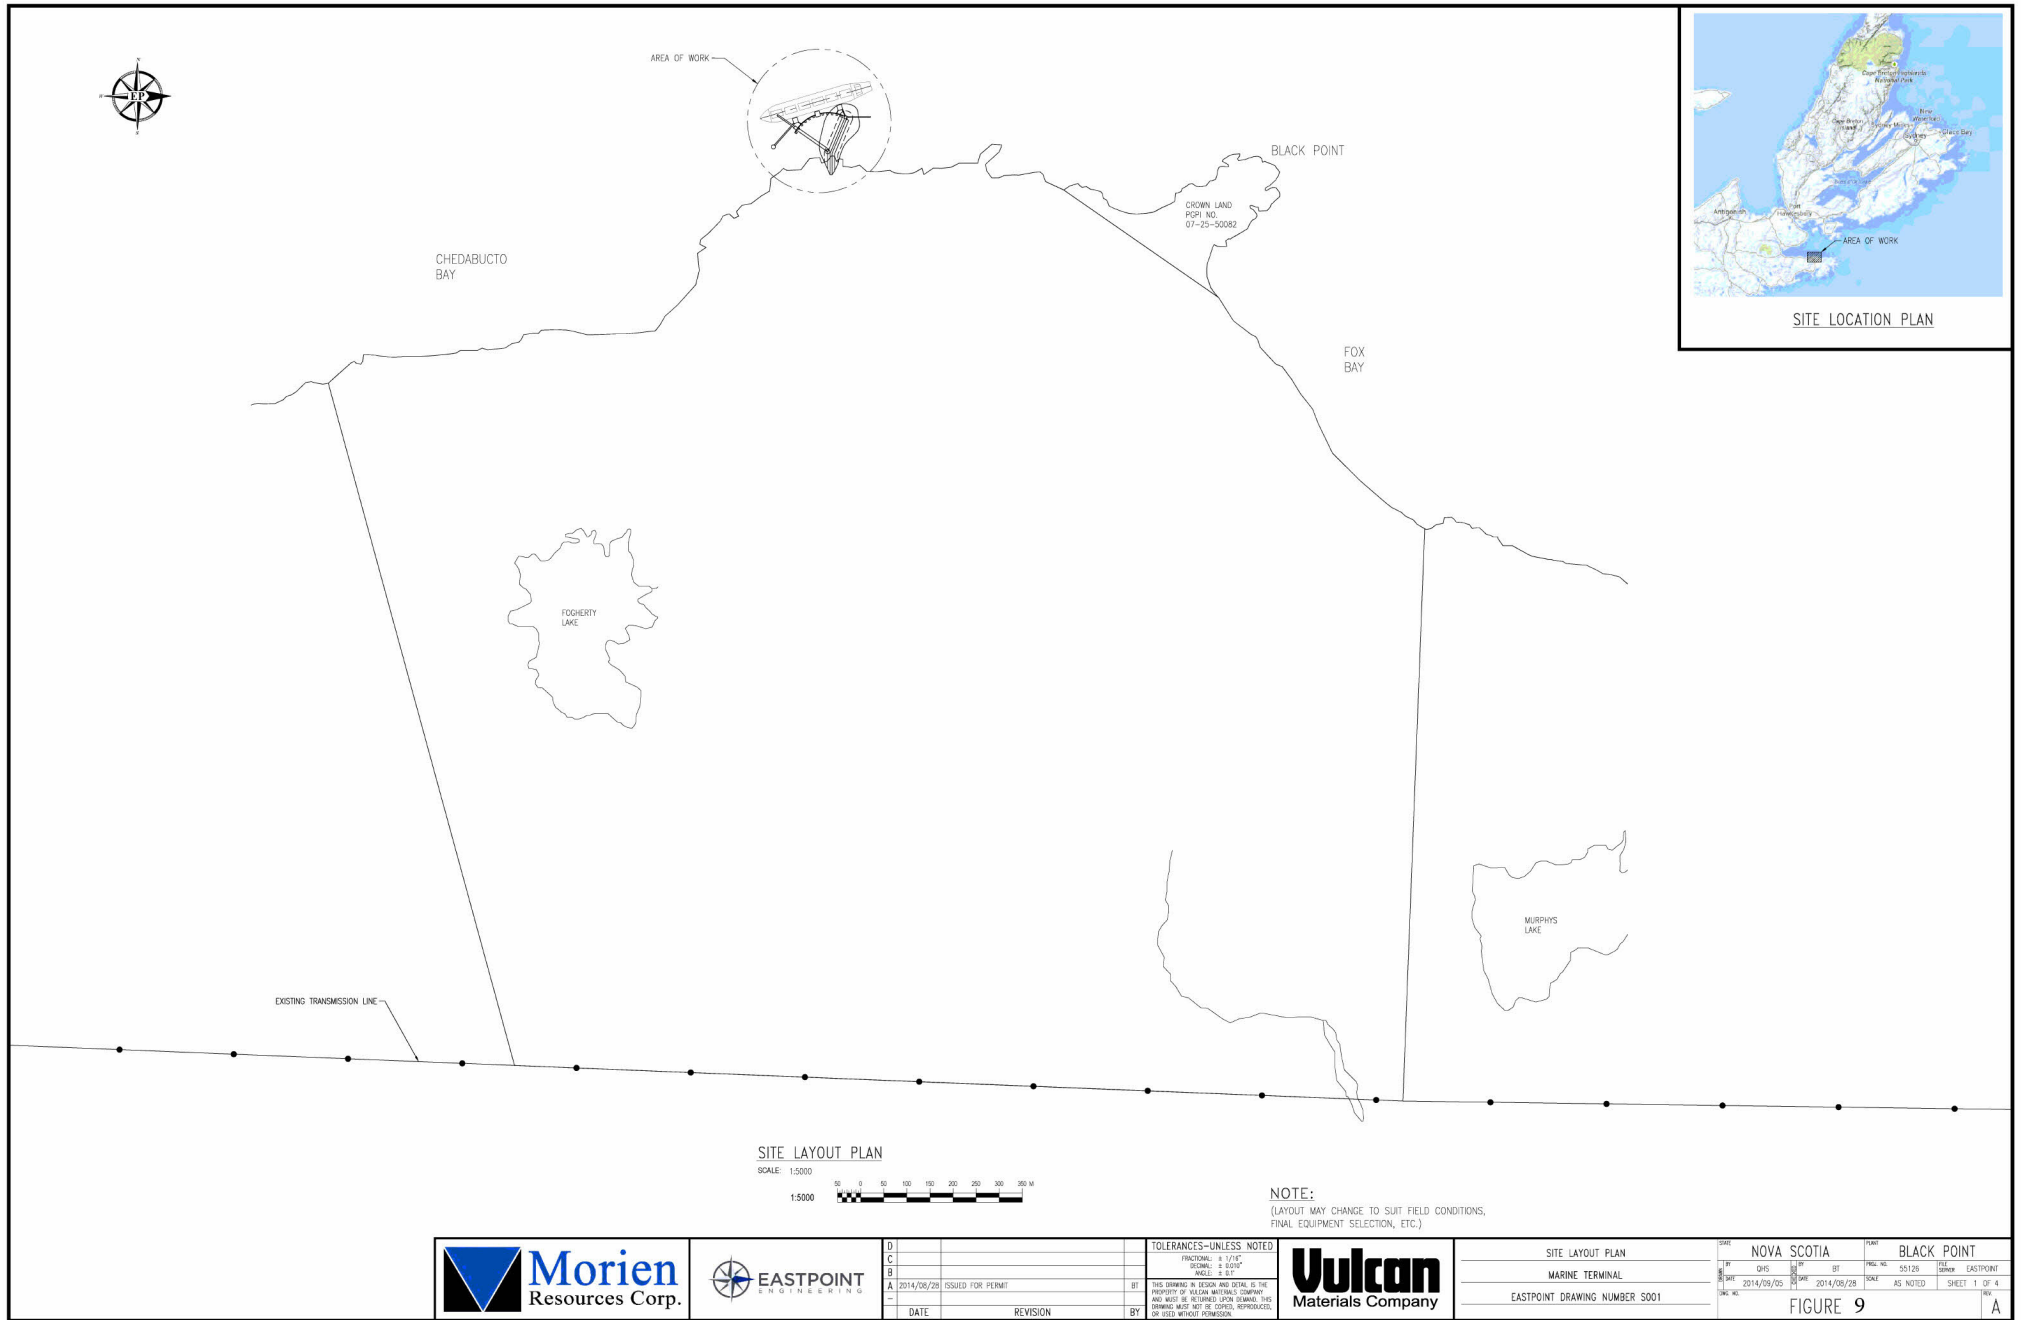

2.4.1 Site Preparation, Cut and Fill

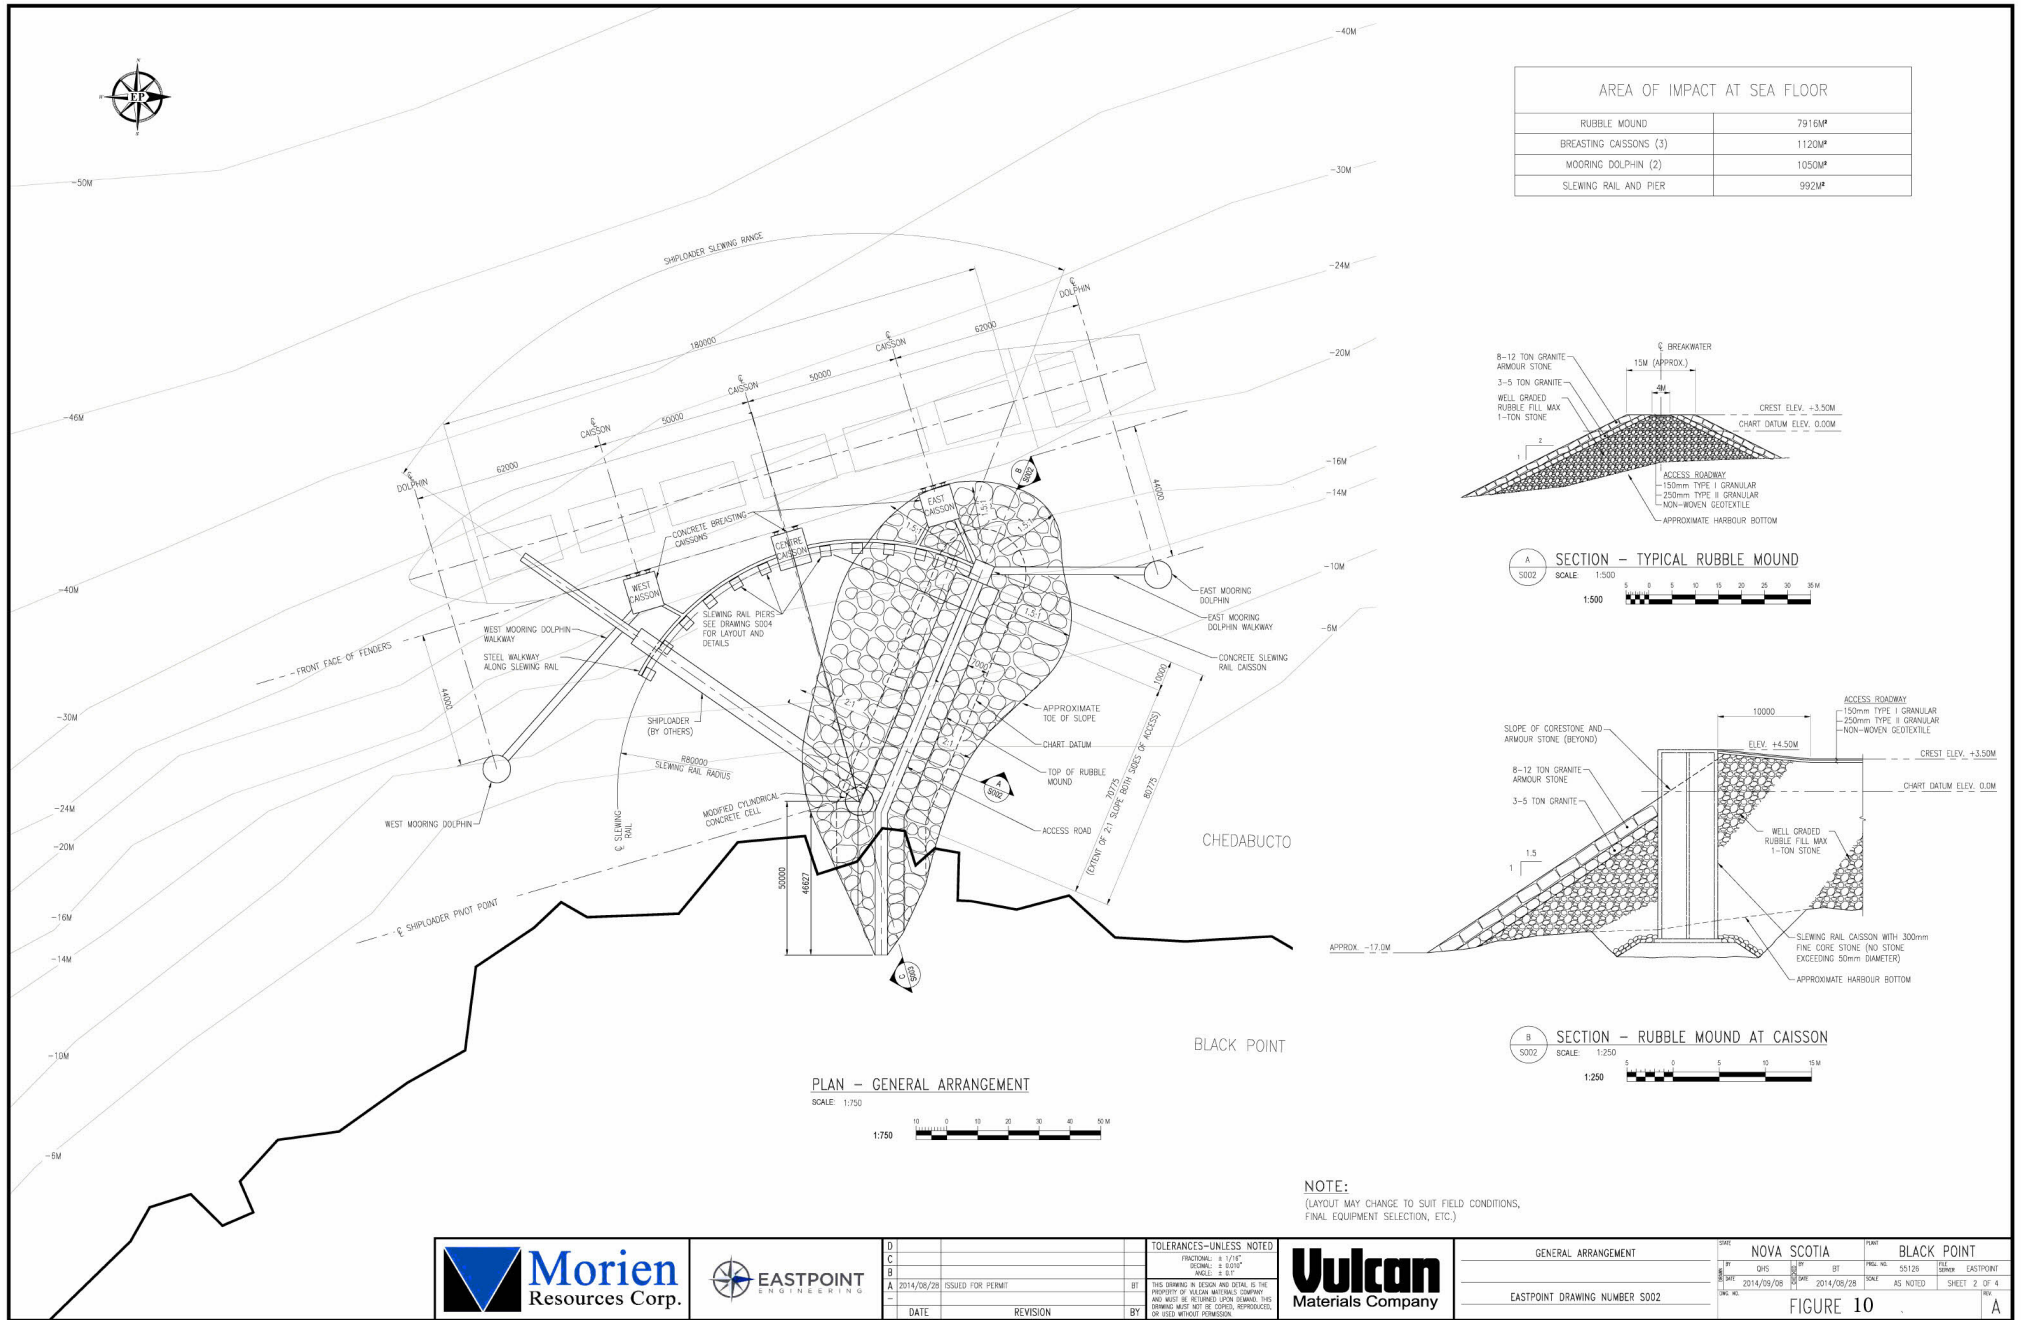

Site preparation will begin with clearing of vegetation and removal/stockpiling of organic material and overburden on the 28 ha plant site and administrative area. Following this, this area will require cut and fill to provide a level surface to construct the processing plant.

A cut or excavation of approximately 600,000 m³ and a fill of 835,000 m³ will be needed to level the area prior to construction. The plant and administrative area will be designed with 1 meter of cross slope drainage which will direct all storm water to two sedimentation ponds. The site preparation and construction phase of the plant site and administrative area is anticipated to occur over a 36 month period.

2.4.2 Marine Terminal Construction

The marine terminal will be constructed from shore using fill and rock (i.e. rip-rap) sourced from the site. Typical construction support includes cranes to lift in reinforcing steel, concrete trucks and pumps and lights for night time activity. The completion of each caisson, once sunk, will take approximately one month. The slewing rail piers will be supported by piles which will be installed from a barge. There will be approximately eleven piers which are expected to have four piles each.

The piles will be installed using pile driving hammers and churn drills and will be anchored in the bedrock. At this time, no dredging appears to be required. Silt curtains and acoustic blankets will be considered during installation, as needed. All marine construction will be completed using conventional marine construction techniques.

Prefabricated steel for the slewing rail and the shiploader will be delivered to the site via barge. Installation will be conducted utilizing cranes and work barges. The loadout conveyor (equipped with aggregate spill containment) will extend from the onshore loadout system to the shiploader. Any piles required for the loadout conveyor in the nearshore area would be located in the rubble fill.

2.4.3 Quarrying

The site will be developed as an open pit quarry using conventional surface mining methods. The mining cycle will include four basic actions:

- Loosening and stockpiling of the vegetation, overburden, and loose rock by dozer and/or track hoe equipment;
- Drilling and blasting to establish benches, haul roads, and sumps for stormwater management;
- Loading of loosened rock into haul trucks by track-mounted and/or rubber tired loading equipment; and
- Transportation of the quarried rock by haul trucks to a discharge point at the edge of the quarry for feed to the primary crusher.

It is anticipated that blasting will occur 30 days per year during the initial project phases, and increase to a maximum of about 200 days per year at full operation. A typical production shot will have less than 100 drill holes each drilled approximately 15 to 17 m deep. Shots utilized for quarry development such as haul roads and sumps will have variable depths generally from 3 to 10 meters.

Freshly mined rock will be transported to and reduced in size by a primary crusher located on a bench on the east side of the quarry. The crushed material will then be transported via conveyor to the processing plant.

2.4.4 Processing Plant Operation

Phase 1

Blasted material will be trucked to the mobile plant and dumped adjacent to the primary module. A loader will then feed the material into the plant. The coarse fill material will be stockpiled by conveyor.

Phase 2

Operation of this plant will be identical to that of the Phase 1 plant. The fine graded fill material will be stockpiled by conveyor and no washing of aggregate will occur during Phase 1 or Phase 2. All material produced will be a base or crusher run product.

Phase 3

Operation of the Phase 3 plant will be similar to that of the earlier phases. In this plant, various products will be stockpiled via conveyor and trucked to the marine terminal. The conveyor feeding the ship loader will include a loadout hopper that can be filled with a plant loader.

Phase 4

In this plant, blasted material will be trucked to the primary crusher where it will be dumped into the primary hopper. There it will be crushed and conveyed to a primary surge pile located near the “secondary” where it will be fed into the plant. As the material is processed with further crushing and screening, it will be conveyed to product piles that are located over “reclaim” tunnels, that is, tunnels equipped with conveyor systems that allow the products to be moved. Products can then be reclaimed to the wash tower for rinsing or bypassed around it. Material will then be stockpiled over the loadout reclaim tunnels that will convey product to the marine terminal.

Phase 5

As noted above, this plant will upgrade the tertiary portion of the Phase 4 plant by installing a parallel tertiary processing circuit. Production through the finishing plant will be increased to 2,800 TPH. Processing and loadout of the material will be identical to the Phase 4 plant but with a higher capacity. The parallel circuit will be identical to the original tertiary to minimize design time and costs.

2.4.5 Ship Loading

The shiploader will load aggregate into the holds of ships (up to 70,000 tonnes) and barges that will transport the material to the end markets. Aggregate loading onto the ships will be via conveyors and will approach 5,000 TPH once the full load-out system is completed. It is estimated that it will take approximately 18 to 24 hours to load the largest ships and that approximately 90-100 ships will be loaded per year once the plant reaches peak production.

2.4.6 Decommissioning

The Proponent will lease the property from the MODG for the life of the quarry, estimated to be sometime after 2070. The land will be returned to the MODG following the completion of operations, equipment decommissioning, removal of plant and marine terminal infrastructure, and the acceptance of site decommissioning and reclamation activities.

In accordance with the requirements of the provincial Pit and Quarry Guidelines (NSEL 1999), the Proponent will prepare a written plan approved by NSE to provide for partial or total abandonment and rehabilitation of the site. It is anticipated that the plan will include an initial rehabilitation plan, progressive rehabilitation measures and / or a final rehabilitation plan. The Proponent will also post interim and final security bonds for the quarry, as required by the Pit and Quarry Guidelines and the *Approval and Notification Procedure Regulations*.

The rehabilitation plan will be developed for the Project site and submitted to regulators for review as part of the provincial Part V Industrial Approval application. The plan will include short-term and long-term reclamation efforts as well as details of the proposed final reclamation plan such as topography, maximum slopes, re-vegetation plans, and potential future land uses once the quarry operation is complete.

All equipment and related infrastructure including the processing plant, machinery and equipment will be removed from the site, provided this is requested by the Municipality who may

wish to keep certain infrastructure on site. The plant site and administrative areas will be graded to allow for future commercial, industrial, recreational, or residential land use, or to allow for restoration of the area to existing conditions to provide wildlife habitat. The pit will be allowed to fill with fresh water to an elevation near sea level.

To avoid disturbance of the marine environment and for potential future use, the rubble mound, mooring dolphins, caissons, slewing rails, and buoys will likely be left in place. The shiploader arm and ancillary mechanical equipment including suspended conveyors, dust collectors and drive belts will be removed from the Project site.

2.5 Project Schedule

Table 2 provides a generalized project schedule that presents the major construction and operational milestones.

**Table 2:
Generalized Project Schedule**

Year	Activity Undertaken or Anticipated
2010-11	Baseline ecological studies initiated
	Initial engagement with the public, regulatory agencies and First Nations
2012-2013	Properties assembled by the MODG (beginning in 2007-2008)
	Environmental Assessment Initiated
2014	<ul style="list-style-type: none"> • Consultation and engagement undertaken: • Meetings and site visits with First Nations representatives • Consultation and site visits with Regulatory Agencies • Meetings with residents and local fishermen • Open Houses, presentations, and meetings of the Citizen's Liaison Committee (CLC) • Submission of the draft EIS for review by the CEA Agency and NSE
2015	Submission of the Environmental Impact Statement report
	Completion of the environmental assessment
2016	Permits and Approvals
Early 2017	Updated Market Evaluation
2017-2018	Establishment of Sales Yards Receipt of Aggregate by Vessel from Black Point
2018-2021	Construction and Equipment Testing (Limited Production)
2021	Commence Full Scale Operations
2070+	Closure and Decommissioning

3.0 SCOPE OF THE PROJECT AND THE ASSESSMENT

3.1 Scope of the Assessment

3.1.1 *Scope of the Project to be Assessed*

The Project is a proposed aggregate quarry comprising the construction, operation and decommissioning of an open pit, processing plant and marine terminal located on a property leased from the Municipality of the District of Guysborough (MODG). The scope of the Project to be assessed under CEAA, 2012 and the Nova Scotia *Environmental Assessment Regulations* includes the following components and activities:

- The stock piles, overburden storage and waste rock;
- The open pit quarry;
- Water supply needs and water management;
- Drilling and blasting activities;
- Solid and hazardous waste and sewage management treatment and systems;
- The processing of extracted materials;
- Noise and dust management;
- Access and power sources and infrastructure;
- The nature and geotechnical properties of geological materials;
- Navigation activities in Canadian waters;
- The construction, operation, maintenance, foreseeable modifications, closure, decommissioning and restoration of the sites and facilities;
- The time of year, frequency, and duration of all project activities; and
- Wharf and port infrastructure and facilities.

No facilities for the manufacture and storage of explosives will be present on site and no capital and maintenance dredging work are expected to be required at this time; these items are excluded from the Project scope.

3.1.2 *Factors to be Considered*

This EIS considers the factors listed in subsection 19(1) of CEAA, 2012 as well as section 79 of the *Species at Risk Act* and section 9.1 of the CEA Agency's Guidelines issued for this Project. This includes consideration of the environmental effects of the Project, the significance of effects, public and First Nation comments, mitigation measures, follow up monitoring programs the purpose of the Project, alternative means of undertaking the Project and the effects of the environment on the Project.

3.1.3 Scope of the Factors to be Considered

As provided in Section 5(1) of CEAA, 2012, the environmental effects that are to be considered regarding an “act or thing, a physical activity, a designated project or a project” are:

- (a) a change that may be caused to the following components of the environment that are within the legislative authority of Parliament:
 - (i) fish and fish habitat as defined in subsection 2(1) of the Fisheries Act,
 - (ii) aquatic species as defined in subsection 2(1) of the Species at Risk Act,
 - (iii) migratory birds as defined in subsection 2(1) of the Migratory Birds Convention Act, 1994, and
 - (iv) any other component of the environment that is set out in Schedule 2;
- (b) a change that may be caused to the environment that would occur
 - (i) on federal lands,
 - (ii) in a province other than the one in which the act or thing is done or where the physical activity, the designated project or the project is being carried out, or
 - (iii) outside Canada; and
- (c) with respect to aboriginal peoples, an effect occurring in Canada of any change that may be caused to the environment on
 - (i) health and socio-economic conditions,
 - (ii) physical and cultural heritage,
 - (iii) the current use of lands and resources for traditional purposes, or
 - (iv) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance

Under Section 5(1) of CEAA, 2012, additional factors must be considered when the Project requires a federal authority to exercise a power or perform a duty or function conferred on it under any Act of Parliament other than CEAA, 2012. In this case, authorizations, approvals and/or permits are required from Fisheries and Oceans Canada and Transport Canada (as a minimum) and so the following environmental effects are also taken into account:

- (a) a change, other than those referred to in paragraphs (1)(a) and (b), that may be caused to the environment and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function that would permit the carrying out, in whole or in part, of the physical activity, the designated project or the project; and
- (b) an effect, other than those referred to in paragraph (1)(c), of any change referred to in paragraph (a) on
 - (i) health and socio-economic conditions,

- (ii) *physical and cultural heritage, or*
- (iii) *any structure, site or thing that is of historical, archaeological, paleontological or architectural significance*

Given this, the scope of the assessment also includes:

- Federal powers, duties or functions that may permit the carrying out of the project or associated activities;
- The environmental and other regulatory approvals and legislation applicable to the project at the federal, provincial, regional and municipal levels;
- Government policies, resource management, planning or study initiatives pertinent to the project;
- Treaties or self-government agreements with Aboriginal groups that are pertinent to the project;
- Relevant municipal planning strategies, land use bylaws, land use zoning, community plans and development permitting processes; and
- The regional, provincial and/or national objectives, standards or guidelines that have been used to assist in the evaluation of any predicted environmental effects.

3.2 Environmental Assessment Methods

3.2.1 Overview of Approach

The goal of applying a defined environmental assessment methodology is to carefully examine the Project and related activities to ensure they will not cause “serious or irreversible harm to the environment, especially with respect to environmental functions and integrity, system tolerance and resilience, and/or the human health of current or future generations” (CEA Agency 2014).

To establish the appropriate scope of an environmental assessment, it is standard practice to limit the assessment to those environmental components that are valued or of interest for ecological, scientific, cultural, regulatory and/or economic reasons. These components are referred to as Valued Components (VCs).

Once the existing condition for each VC is known, the environmental assessment:

1. Predicts the Project-related environmental effects or impacts and evaluates the scope and scale of these effects;
2. Describes a number of mitigation measures and practices that the Proponent will use to avoid, minimize, eliminate, mitigate, or compensate for the effects;
3. Assesses the cumulative effects from other probable future projects; and
4. Determines the residual effects remaining after mitigation and assesses the significance of these effects on each VC.

3.2.2 Identification of VCs

An internal issues-scoping exercise was undertaken to identify the VCs of both general and project-specific interest. For the Black Point Quarry Project, provisional VCs were identified through:

- Discussions with federal and provincial regulatory agencies;
- A review of the EIS Guidelines prepared for this Project;
- A review of applicable provincial and federal regulation;
- Discussions with government scientific authorities;
- Previous environmental studies conducted on site;
- Comments raised through various public meetings and outreach events;
- A review of information submitted in support of nearby and similar environmental assessments; and
- The professional experience of the Project team.

Based on this methodology, the following VCs were selected for assessment:

1. Air Quality and Climate Change
2. Noise
3. Ambient Light
4. Geology, Soil & Sediment Quality
5. Groundwater Resources
6. Marine and Surface Water Resources
7. Terrestrial Ecosystems, Habitat & Vegetation
8. Wetlands
9. Terrestrial Wildlife
10. Freshwater Species and Habitat
11. Marine Species and Habitat
12. Species at Risk
13. Local Economy, Land and Resource Use
14. Tourism and Recreation
15. Commercial Fisheries
16. Archaeological and Heritage Resources
17. Aboriginal Land and Resource Use

3.2.3 Boundaries

Temporal boundaries represent the duration over which the Project activities interact with each VC. In general, the temporal boundaries are (a) the construction period, and (b) the operating life of the Project, through to decommissioning and reclamation.

Spatial boundaries are those geographic limits that help define the scale and range of the interactions between the Project and each VC. The following spatial boundaries are used for this assessment.

1. The **Project Area** is confined to all territory within the limits of the Project property boundary;
2. The **Affected Area** is the area which could potentially be affected by Project components or activities immediately beyond the PA. The Affected Area is similar to the area directly adjacent the Project property but can be larger depending on the component being considered.

The extent to which the Affected Area is within the spatial boundaries of the Project is VC-specific and dependent on biological and physical considerations. For most VCs the Affected Area is generally within two kilometers of the Project Property limit.

3. The **Study Area**: the Study Area is defined by considering all Project-environment interactions, including diffuse or longer range effects such as noise and light, which can only be modeled at this time. It may include, for example, the waters of Chedabucto Bay south of the shipping lanes where the Project-related marine activities and interactions will occur; for other VCs the SA may include the MODG where the majority of the social and economic effects can be expected.

Technical boundaries represent limits to the Project team's ability to assess a VC, pathway or receptor. A technical boundary is a theoretical or actual limitation on the ability to measure, assess, and/or monitor potential environmental effects.

Administrative boundaries are those limits that originate through regulatory, public policy or economic reasons. Where applicable, administrative boundaries are described in each VC chapter.

4.0 ALTERNATIVE MEANS OF UNDERTAKING THE PROJECT

Section 19(1)g of CEAA, 2012 requires that federal environmental assessment consider alternative means of undertaking a project and the consequent environmental effects of such alternative scenarios.

Table 3 summarizes the alternatives assessment.

Table 3:
Summary of the Alternative Means of Undertaking the Project

Project Component	Alternative Means	Technical Feasibility	Economic Feasibility	Environmental Effects	Preferred Option
Quarry Location	Black Point Site	Technically Feasible	Economically Feasible	A number of environmental effects are associated with any quarry development; no significant residual environmental effects are anticipated at the Black Point site.	Yes
	Other Nova Scotia Sites	Not Technically Feasible considering the range and specificity of the geographical and resource requirements	Not Economically Feasible based on the Proponent's analysis and given the high-bulk low-cost nature of the aggregate resource	Not assessed since no feasible alternative site was identified	No
Rock Extraction Method	Drilling and Blasting	Technically Feasible	Economically Feasible	Environmental effects are similar in both alternatives: will result in noise and dust impacts	Yes
	Ripping	Not Technically Feasible considering the hardness and density of the granite resource	Not Economically Feasible	Environmental effects are similar in both alternatives: will result in noise and dust impacts	No
Development and Transportation	Rock Face Open Pit	Technically Feasible	Economically Feasible	Environmental effects are largely similar under both mining options	Yes
	Glory Hole Open Pit	Not Technically Feasible primarily due to worker safety considerations	Economically Feasible but additional infrastructure would significantly increase production costs	Potential social (human health) effects are greater in the glory hole scenario due to increased worker exposure to accidents and malfunctions	No
	Transport via Ship from Dedicated Terminal	Technically Feasible	Economically Feasible	Environmental effects relate primarily to Local Economy, Land and Resource Use; shipping related effects are similar in both scenarios.	Yes
	Truck Transport to an Existing Terminal Followed by Transport via Ship (e.g., Auld's Cove)	Technically Feasible	Not Economically Feasible due to truck transportation costs, which would eliminate profitability	Significantly more environmental and economic impacts due to truck traffic through rural and residential areas. Increased air and noise emissions in this scenario.	No

Marine Terminal Location	Eastern Location	Technically Feasible	Economically Feasible	Environmental effects are similar under both alternatives. The VCs Marine Species and Habitat and Commercial Fisheries and Aquaculture would be affected in a similar manner at both terminal locations.	Yes
	Western Location	Not Technically Feasible due to shallow water depths	Economically Feasible	As above; this location is also slightly more sheltered from winds originating to the northeast.	No
Marine Terminal Construction	Rubble Mound Wharf	Technically Feasible and permits the secure storage of acid generating rock; more operationally efficient since it permits vehicular access to ship mooring points for maintenance	Economically Feasible; less expensive to design, build and maintain	Both approaches would affect Marine Species/Habitat and Commercial Fisheries to approximately the same degree. Rubble Mound Wharf occupies more seafloor than the Concrete Caisson Wharf but the rubble would eventually act as lobster habitat.	Yes
	Concrete Caisson Wharf	Technically Feasible but less stable in severe weather; more dangerous to maintain since boat access would be needed.	Economically Feasible	Concrete Caisson Wharf occupies less seafloor than the Rubble Mound Wharf but would shade the seafloor, negatively affecting habitat quality and use.	No
Stockpile Locations	Western End Opposite the Marine Terminal	Technically Feasible	Economically Feasible: this location is both operationally and economically more practical.	In both alternatives, several wetlands would be lost	Yes
	Eastern End near Wetland 2	Technically Feasible although it greatly increases the complexity of operation and may introduce occupational health and safety risks	Not Economically Feasible: this location requires a complete reconfiguration of processing plant and a much longer conveyor system to deliver aggregate to the marine terminal.	In addition to wetland loss, Wetland 2 is potentially exposed to runoff from the stockpiles in this alternative	No
Waste Management	Collection tank for septic wastes with transport and treatment at the Canso	Technically Feasible and practical	Economically Feasible and cost effective	Minimal impact to Groundwater Resources and Marine and Surface Water Resources.	Yes

	municipal waste water treatment facility				
	Other septic treatment systems: conventional septic tank and leach field, raised bed systems, rotating biological contactors, peat-based treatment systems, constructed wetlands, and recirculating sand filtration	Not Technically Feasible due to lack of soil cover (conventional leach field): Technically Feasible but poor operational records when applied to operations at this scale (non-conventional treatment systems).	Economically more expensive to design, purchase, operate and maintain	Varying long term impacts can be expected to Groundwater Resources and Marine and Surface Water Resources through treated effluent discharge.	No
	"Crusher fines" storage outside of the quarry	Technically Feasible	Economically Feasible but more expensive considering the increased transport distance to the storage site and the greater number of times the materials would be handled	Increased risk of accidental discharge with potential negative effects on Marine and Surface Water Resources, Terrestrial Ecosystems, Habitat & Vegetation, Wetlands, and Terrestrial Wildlife. Similar anticipated effects (i.e., minimal) on Groundwater Resources in both alternatives. Increased handling and transport increases impacts to air quality.	No
	"Crusher fines" storage within the quarry	Technically Feasible	Economically Feasible	No risk of accidental discharge to the environment (potentially affecting Marine and Surface Water Resources, Terrestrial Ecosystems, Habitat & Vegetation, Wetlands, and Terrestrial Wildlife)	Yes
Electrical Supply	Tie-in to the existing electrical transmission line	Technically Feasible	Economically Feasible; more expensive over the short term but costs are recovered over the longer term.	Environmental effects associated with habitat and vegetation loss within the right of way are minimized by using the same right of way for the access road.	Yes
	Use of multiple on-site generators	Technically Feasible	Economically Feasible but more expensive over the long term due to fuel, lubricant and transport costs, as well as maintenance and operating costs	Increased risks of fire and fuel spills given the generators' fuel requirements; increased impacts to ambient noise levels; increased GHG emissions	No

5.0 PUBLIC AND ABORIGINAL ENGAGEMENT

The Proponent implemented a comprehensive consultation program with the following objectives:

- to identify issues and concerns of interest to the affected communities, stakeholder groups and residents;
- to assist in judging the nature and intensity of Project benefits or impacts;
- to solicit local information and expert opinions; and
- to fulfil regulatory requirements.

5.1 Public Engagement

The Proponent has informed stakeholders of the Project, explained the planning and regulatory processes, advertised consultation and engagement opportunities and solicited input into the Project Description and the EIS report. Engagement tools and techniques that have been applied during the public consultation program include:

1. a Project-specific website – www.blackpointquarry.ca
2. a stakeholder database including email and mailing lists used for email outreach to interested residents and others;
3. an open house event, public information sessions and public presentations;
4. public notices regarding key milestones and Community Liaison Committee membership;
5. interviews with provincial and local media outlets;
6. a Project newsletter distributed via mail drops, newspaper inserts and email;
7. the Community Liaison Committee (CLC);
8. government agency briefings (federal, provincial and local); and
9. other stakeholder group meetings and door-to-door introductions to residents.

5.1.1 Stakeholder Consultation Activities

To date, eleven outreach communications have been provided to people and organizations on the mailing list (Table 4).

Table 4:
Stakeholder Outreach Communications

Date	Item	Distribution Method	Approximate Total Distribution
April-09-14	Open House Announcement	Ad in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses
April-14-14	Morien Press Release re: Vulcan and the Project	Newswire / Press Release	>900 Canadian news outlets
April-17-14	Open House Announcement	Canada Post Mail Drop	3,000 households; does not incl farms, business, apartments
April-22-14	Display Boards, Vulcan Presentation Booklets	Hand-outs at the Open House	200+ attendees
April-30-14	CLC Member Solicitation	Ad in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses

July-07-14	Project Fact Sheet	Canada Post Mail Drop	3,000 households; does not incl farms, business, apartments
July-30-14	Summer 2014 Newsletter	Pamphlet in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses
August-27-14	CLC Member List	Ad in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses
Dec-19-14	Frequently Asked Questions	Canada Post Mail Drop	3,000 households not including farms, business, apartments
Jan-13-15	GCIFA Endorsement	Newswire / Press Release	>900 Canadian news outlets
Feb-4-15	Winter 2015 Newsletter	Canada Post Mail Drop	3,000 households not including farms, business, apartments

The first Open House was held at the Queensport Fire Hall in Guysborough on April 22, 2014. The goal of the Open House was to inform the community about the Black Point Project and the environmental assessment process, and describe anticipated Project timelines. A second Open House has been tentatively scheduled for mid-March, 2015.

The Proponent has been asked by several media outlets to provide comment or updates on the Project. The Proponent was interviewed on ten occasions since April 2014.

The Summer 2014 Black Point Quarry Project Newsletter was distributed on July 30, 2014. The Winter 2015 newsletter was distributed on February 4, 2014. The Newsletters were emailed to the Project stakeholder mailing list and was distributed by Canada Post to residents in Guysborough County. Copies are available on the Project website.

In mid-2014, the Proponent established a Community Liaison Committee consisting of eight local representatives to help document community concerns and distribute updates regarding the Project. The CLC has met on two occasions to date, in August and in October, 2014. The next CLC meeting is tentatively scheduled for mid-March, 2015.

The Black Point Quarry Project team has been consulting with government officials and regulators (municipal, provincial, and federal) on an ongoing basis. The objective of these consultations is to provide information and updates on the Project and the environmental assessment, and also to receive input and guidance as appropriate.

Additionally, several presentations have been given to various groups interested in the Project. These community presentations are provided in Table 5.

Table 5:

Introduction to Vulcan Materials and the Project	Geology Matters Conference, NS Department of Natural Resources	November 13, 2014
Introduction to Vulcan Materials and the Project	Strait Area Chamber of Commerce	December 2, 2014

The Proponent has met with representatives of the Guysborough County Inshore Fishermen's Association (GCIFA) on three occasions since April, 2014 and has met local fishermen individually and in groups on at least four occasions.

To ensure the residents bordering the proposed Project had the opportunity to learn about the Project, pose questions, express concerns. Proponent representatives went door-to-door along Half Island Cove Road, Upper Fox Island and Fox Island Main in July, 2014. In total, 17 of 25 addresses were visited and face-to-face meetings held. Of the 8 unvisited residences, 4 occupants were not home while 4 addresses were not occupied (i.e., for sale or apparently abandoned).

5.1.2 Stakeholder Questions and Comments

Stakeholder issues have been formally compiled since January 2014 and are generally grouped by stakeholder group: local residents in the immediate Project vicinity, people in the commercial fishing industry, Aboriginal groups, and other interested stakeholders. Issues and concerns can be summarized by the following themes:

1. Questions regarding the training and skill requirements, technical operation and timing of the Project;
2. General concerns regarding environmental effects in the terrestrial environment, typically related to property values, noise, dust and water quality; and
3. Questions and concerns respecting Project effects to the commercial fishing industry, typically regarding siltation, shipping routes, fishermen displacement and the loss of fishing grounds, effects of the marine terminal and Project operation (including blasting) on the behaviour of commercial species and the possibility of invasive species imported in vessel bilge water.

Specific questions and concerns by stakeholder group are documented in Section 11 of the EIS. A log of meetings held and questions raised is presented in Appendix M Attachment 4 of the EIS.

5.2 Aboriginal Engagement

The Proponent has undertaken several measures to identify the concerns of Mi'kmaq communities, through their designated representatives, about potential environmental effects of the Project, and to promote First Nation involvement in the Project.

The Proponent has addressed early engagement with the Aboriginal community in Nova Scotia as a priority and has developed an Aboriginal Community Engagement Strategy, which commenced several years prior to the filing of the Project Description in February 2014. The premise of the engagement strategy is that, through effective engagement, the Proponent can establish an effective relationship with Aboriginal communities and organizations.

The Proponent's objectives were to:

- inform Aboriginal communities about its proposal;
- solicit information on the Aboriginal issues and concerns with respect to the proposed Project; and
- identify ways and means for Aboriginal engagement in the planning process and approaches to a mutually beneficial Project implementation.

5.2.1 Aboriginal Organizations

Based upon a preliminary assessment of the Project location and the known activity of Mi'kmaq communities in Nova Scotia, several communities and Mi'kmaq organizations were identified as potentially affected and/or having a direct interest in the Black Point Quarry Project. These communities and organizations are listed in Table 6.

**Table 6:
Key Mi'kmaq Communities and Groups**

Category	Communities/Organizations
Mi'kmaq communities	Paqtnekek First Nation
	Millbrook First Nation
	Sipekne'katik First Nation
Mi'kmaq organizations	Assembly of NS Mi'kmaq Chiefs Kwilmu'kw Maw-Klusuaqn (KMK) Negotiations Office
	KMK Benefits Committee Sipekne'katik Negotiations Office
Provincial government organizations	Nova Scotia Office of Aboriginal Affairs

5.2.2 Aboriginal Consultation Activities

The engagement activities undertaken to date are listed in Table 7. In addition, invitations to all Public meetings/Open House events were sent to representatives of the Mi'kmaq communities identified in Table 6.

Table 7:
Mi'kmaq Engagement Activities

Mi'kmaq Community Engagement Activities	Date
Face to Face Contacts with Chiefs	
Paqtnkek	Oct 12, 2010 (initial meeting with Chief)
Millbrook	Mar 21, 2011 (initial meeting with Band Manager) May 7, 2014
Sipekne'katik	Jun 18, 2014 Aug 12, 2014 (site visit)
Presentations / Meetings with Communities

Chief W. Marshall, K. Prosper	October 27, 2014

5.2.3 Aboriginal Questions and Comments

Issues and concerns identified during the Aboriginal engagement process are summarized in Table 8. Based on discussions during these engagement sessions, there is a general understanding between The Proponent and Mi'kmaq communities that the engagement process will continue to facilitate open dialogue on matters related to Mi'kmaq interest regarding environment and economic development.

Table 8:
Comments and Issues Raised by Mi'kmaq Communities

Subject Area	Comments/Concerns/ Suggestions	Study Team Responses/Actions
Opportunities (Economics, Training, Other)	Seeking engagement in accordance with Proponents Guidelines, issued by the NS Government	Initiated communication with Chiefs and KMK; made commitments in a draft MOU pertaining to development of long-term relationship and provision of Project benefits.
	Potential for collaboration and employment	Negotiation of a collaborative benefits agreement.
	Potential for training and skills development	Including training in negotiation of benefits agreement.
	Potential for support for KMK operations	MOU includes negotiation of support to facilitate development of benefits agreement.
Planning Process	MEK Study	MEKS updated and submitted for review.
	Environmental protection	Providing opportunity for direct review of the EA document (made presentation and provide means to facilitate

Subject Area	Comments/Concerns/ Suggestions	Study Team Responses/Actions
Review of EIS Guidelines/KMK meetings	Request internal review of MEKS	feedback).
		Agree. A copy of the MEKS has been provided for review and comment.
	Concerns for fish, fish habitat, and Mi'kmaq fisheries	A MEK Study has been prepared as part of the EA process. This includes a discussion of potential effects on fishing. The Proponent's engagement program with Mi'kmaq communities has addressed potential project-related effects and establishes commitments for effects management and communication.
	Identified concerns for archaeological assessment	A MEK Study and archaeological assessments have been prepared as part of the EA process. This includes a discussion of potential effects on archaeological sites. The Proponent's engagement program with Mi'kmaq communities also addresses potential project-related effects and establishes commitments for archaeological fieldwork and documentation. In addition the Proponent has committed to a separate site visit being undertaken with a qualified Mi'kmaq archaeologist prior to project implementation
	Kwilmu'kw Maw-klusuaqn Negotiation Office may coordinate Mi'kmaq representation in CLC.	The Proponent has established a CLC and invited Mi'kmaq community to be represented; the Sipekne'katik band is represented.
Consultation and Engagement	Identified expectations for impact benefits agreement.	The Proponent has commenced and will continue to engage Mi'kmaq communities in the Project's planning and development process. As such the Proponent is in the process of negotiating with the Kwilmu'kw Maw-klusuaqn Negotiation Office a comprehensive Cooperation Agreement.
	Crown responsibilities and activities regarding consultation with Mi'kmaq communities about the Project.	Maintaining direct dialogue with Mi'kmaq organizations and communities without prejudice. Maintaining arm's length discussions with Office of Aboriginal Affairs.
	Distinction between Crown Consultation and Proponent Engagement.	Proponent is ensuring Project staff is not directly involved in negotiations between NS Government and First Nations negotiators.

The Proponent is in negotiations to conclude a memorandum of understanding (MOU) with the Assembly of Nova Scotia Chiefs through the KMK Benefits office and a separate MOU is being negotiated with the Sipekne'katik First Nation. The purpose and focus of these MOUs is to guide ongoing discussions regarding collaborative benefits agreements between the Project and Mi'kmaq communities. Discussions have been ongoing since spring, 2014 and are proceeding in an open and constructive manner.

6.0 SUMMARY OF THE ENVIRONMENTAL EFFECTS ASSESSMENT

6.1 Air Quality and Climate Change

Air Quality is identified as a VC since air quality concerns associated with the generation of dust have been raised by community residents and First Nations. Air quality is also a pathway to the food chain via the transport of dust and deposition of contaminants on vegetation and surface water. Air quality within the quarry is of interest to provincial workplace health and safety regulators.

6.1.1 Potential Environmental Effects

The construction and operation of the facility will result in dust emissions (total particulate matter [TPM], total suspended particulate [TSP], particulate matter up to particle size 10 microns [PM₁₀] and particulate matter up to particle size 2.5 microns [PM_{2.5}]). The sources of dust emissions associated with the Project include:

- crushers
- screens
- material loading/unloading
- material conveyors and transfer
- wind erosion of material storage piles and exposed areas
- blasting
- overburden removal, and
- vehicle traffic (haul roads).

Fuel combustion in mobile and fixed equipment, vehicles, and ships will result in emissions of criteria air contaminants including sulphur dioxide, nitrogen oxides, volatile organic compounds, carbon monoxide, and particulate matter. Fuel combustion will be a source of Project greenhouse gas emissions, which include carbon dioxide, methane, and nitrous oxide.

In order to quantify air contaminant dispersion during quarry operations, including those from vessel emissions, a detailed air dispersion modelling study was undertaken. The air dispersion modelling results demonstrate that even under worse case scenarios, Project-related air contaminants at the nearest residences are far below the maximum acceptable concentrations established by provincial and federal regulation. In particular, the predicted 1-hour and 24-hour maximum, and the annual average concentrations for nitrogen dioxide (NO₂), sulphur dioxide (SO₂), and particulate matter (including TSP, PM₁₀ and PM_{2.5}), as well as the 1-hour and the 8-hour maximum concentrations for carbon monoxide (CO) were found to be at least 50% below their respective objectives. This in turn demonstrates that air impacts at federal lands further from the property will be negligible.

The details of the air quality assessment are provided in Section 7.1 of the EIS report.

6.2 Noise

Activities such as blasting and aggregate processing will produce noise and have the potential to alter the ambient noise conditions of the local area. Noise concerns have been raised by residents living to the east and west of the Property. Changes to ambient noise may also affect a variety of wildlife, migratory birds and Species at Risk (SAR) through driving them out of the area and/or other effects on their behaviour.

Construction of the marine terminal will likely result in temporary increases to noise in the marine environment, which may in turn affect nearby marine biota. Noise may alter the behaviour patterns of certain marine species, which may in turn affect these species at different times of their life cycles. Shipping associated with the marine terminal will add to the noise already present in the marine environment.

6.2.1 Potential Environmental Effects

Under the worst case scenario, the predicted noise levels at the nearest residences during the daytime and evening range from 47 dBA to 55 dBA, complying with the most stringent noise limit of 55 dBA. Quarry production noise is generally characterised by low-frequency “rumbling” noise that does not vary much with time. Quarry noise will be audible at a “moderate to quiet” level in nearby residential areas.

The predicted noise levels at the nearest residences during night-time range from 25 dBA to 41 dBA, complying with the night-time limit of 55 dBA. The night-time noise level would not be expected to disturb the sleep of most people in the long term.

The minimum blasting distance to the nearest residence (800 m) is respected in all directions from the Property boundary.

6.3 Ambient Light

The Project site is currently undeveloped and night time ambient light conditions are low. Changes to ambient light conditions have the potential to negatively affect wildlife, including birds, in the immediate area. Increases in night time light levels may also be perceived as a nuisance by local residents.

6.3.1 Potential Environmental Effects

Ambient light levels will increase during the construction of the processing plant, associated infrastructure and the marine terminal. Other lighting introduced to the site will come from vehicle headlights moving around the site as well as entering and exiting the site at the intersection with Route 16.

The topography blocks views of the quarry from the south and so there will be no significant light trespass on any buildings along Route 16. From the west, the topography prevents direct line of sight view to the quarry, processing plant and marine terminal, except for viewers standing directly on the coast and those who may look toward Black Point from the east side of Gaulman Point. From these vantage points, the marine terminal and stockpiles will be visible, but the quarry will be largely concealed behind a vegetated coastal buffer.

To the east, direct line of sight viewers are located on the east side of Indian Cove along Fox Island Cove Road. Black Point can also be seen from the beach at Indian Cove, located 3.5 km east of the proposed processing plant. From this direction, much of the processing plant, quarry and marine terminal is expected to be shielded from view by Black Point itself (which will remain forested), as well as a 30 m wide vegetated buffer left along the coast. It is likely the tallest components of the processing plant (conveyers, tops of stockpiles, and lighting fixtures) may be visible from these eastern viewpoints.

At night, many nocturnal animals use moonlight and starlight to forage for food and detect predators. Objects in the night sky may be used as aids to navigation for migrating birds. Patterns of light and darkness are also used to regulate circadian cycles; to control the behavior of diurnal, nocturnal and crepuscular animals¹; to determine day length; and as a directional cue

¹ Diurnal animals are most active during the day; nocturnal animals are most active at night; crepuscular animals are most active at dusk and dawn.

for navigation. Lighting needed to illuminate working areas and for navigational purposes at the marine terminal can have an adverse effect on migrating birds. Birds that enter these illuminated areas can become confused possibly resulting in collisions and mortality.

6.4 Geology, Soil and Sediment Quality

Geology, Soil and Sediment quality was identified as a VC primarily due to the anticipated disturbance of potentially acid generating rock during site levelling for the processing plant, as well as concerns expressed by fishermen with respect to the discharge of sediment-laden water from the Project site and the consequent effects on lobster and their habitat.

6.4.1 Potential Environmental Effects

The granite rock that will be quarried for aggregate is not acid generating. In contrast, Halifax Formation sedimentary rocks that underlay a small portion of the site near the coast (approximately 11.8 ha) may generate acid and/or leach metals when exposed to oxygen. This water may negatively affect the nearshore marine environment if allowed to drain to Chedabucto Bay.

Discharge or runoff of sediment-laden water during construction and operation may have harmful effects on nearby lobster habitat or lobster life stages.

6.5 Groundwater Resources

Groundwater extracted from dug and drilled wells is used for drinking water purposes by the nearest residents living to the east, west and south of the Project site. A total of 23 residences are located in the vicinity of the Project (within 2 to 3.5 km); of these, 17 employ dug wells while 6 employ drilled wells. No water wells are installed in the granite rock that will be quarried.

Groundwater quality and quantity also contributes to the health and sustainability of local ecological systems.

6.5.1 Potential Environmental Effects

The Project will remove granite from within the Property boundaries, ultimately creating a pit approximately 130 m deep. Once pit development begins, surface precipitation that originally landed on the granite and flowed laterally to help recharge nearby wetlands and lakes will be redirected into the pit, negatively affecting these ecological features.

With respect to potential Project effects on the surface water aquifers that support dug wells, no Project-related impacts are expected. This is because these aquifers are fed by surface precipitation falling within the subcatchments that host the wells and not by precipitation falling on areas that will be developed for the Project. For those who use drilled bedrock wells to obtain potable groundwater, Project-related impacts to potable groundwater supply and quality will be negligible because:

1. There is no potable groundwater wells drilled in the granite.
2. Drilled wells within the highly fractured metasedimentary rocks access a chemically different groundwater than the one present within the granite. These aquifers are not only chemically different, they are structurally different. While a certain connectivity can be expected, the

fact that the water chemistry is different indicates that the connectivity is minimal and slow to occur.

3. Even at full pit build out, a thick barrier of granite (over 400 m wide) will remain between the pit wall and nearest metasedimentary bedrock where drilled wells are located (even further away). This thick barrier helps to isolate Project-related effects within the granite from affecting the aquifer tapped by wells in the metasedimentary bedrock.
4. The nearest drilled groundwater well is located 815 m from the pit boundary, far outside of the maximum potential drawdown cone resulting from the pit (400 m); the next nearest drilled well is more than 2.5 km from the pit boundary. The sheer distance provides a significant measure of security for drilled wells in the vicinity of the Project.
5. Because the groundwater movement within the granite is expected to be limited, no groundwater dewatering will be needed to prevent groundwater inflow into the pit (inflows will be simply collected in the sump). The lack of active dewatering wells means that the cone of influence is limited to the zone caused by passive drainage into the pit.

6.6 Marine and Surface Water Resources

Surface Water Resources are considered to be a VC because they sustain aquatic ecosystems and support terrestrial ecosystems, convey stormwater, and can either recharge groundwater resources or drain excess groundwater away from an area. Marine water quality is fundamental to healthy marine ecosystems and is critical to the long term success and sustainability of the commercial fishery. No terrestrial fish habitat is present on the site due to the natural acidity of the water.

6.6.1 Potential Environmental Effects

The Project may impact upon the baseline hydrological regime by increasing or decreasing flows to, or water levels within surface water resources. This in turn may impact upon established aquatic ecosystems, or (during extreme events) additional runoff may increase the risk of flooding within the downstream environment. Additionally, the development may impact upon surface water quality through accidental spills or uncontrolled erosion, which may in turn affect established aquatic ecosystems. Downstream flow to Reynolds Brook, located 1.0 km south of the Property, is expected to be reduced by up to 18% at full quarry build out. This may have negative effects on fish populations (if present) during periods of low flow, or alternatively, may improve water quality by reducing inflows of low pH surface water.

Marine water quality may be negatively affected by sediment laden water in the form of discharge or stormwater runoff. Acid rock drainage generated from the disturbance of Halifax Formation rocks may also affect marine water quality.

6.7 Terrestrial Ecosystems, Habitat and Vegetation

Terrestrial ecosystems, habitat and vegetation express local and regional biodiversity and support ecological resilience. These features form the basis upon which local wildlife populations depend. First Nations have expressed concerns with respect to their continuing ability to harvest terrestrial resources within the Project and adjacent areas, as well as the overall effect of Project activities on ecological resources in general.

6.7.1 Potential Environmental Effects

Terrestrial ecosystems and habitat will be permanently diminished or destroyed, and vegetation will be lost during the course of building and operating the Project. Indirect impairments to ecosystems and habitat may occur through Project-related activities such as water use, accidental spills, and dust emissions.

6.8 Wetlands

Wetlands are highly productive and diverse ecosystems that perform a number of biophysical and ecological functions. They may provide habitat or refuges for a diversity of species (including SAR), attenuate storm flows, recharge groundwater and provide discharge to downstream receptors during dry periods.

6.8.1 Potential Environmental Effects

Over the 50 year life of the Project, development will directly affect a number of wetlands on the Project site, and may indirectly affect others through effects to surface and groundwater flows or from inputs from accidental hydrocarbon spills or quarry dust. Those wetlands directly affected will be permanently destroyed or diminished. These effects will not be felt at once, but rather progressively as the quarry expands over its 50 year production life.

6.9 Terrestrial Wildlife

Terrestrial wildlife species have ecological, aesthetic and recreational importance to the public and First Nations, primarily as a food source and as an economic and recreational resource. They also have inherent value as wild species and critical components of larger ecosystems.

6.9.1 Potential Environmental Effects

Project development will impair or eliminate the productive capacity of some terrestrial habitat within the Project footprint. Other indirect interactions (airborne dust, emissions, noise, vibration, light, water use) may affect species and habitat adjacent to the Project.

The main impact on landbirds will be the loss of nesting and foraging habitat. Vegetation clearing and grubbing activities may also cause destruction of nests and nestlings or eggs if conducted during the breeding season. In addition to habitat loss, construction noise (including blasting) may have deleterious effects on animals in and near the Project area.

No evidence of breeding shorebirds was reported during the field surveys. Disturbance due to construction noise (including blasting) is expected to have minor impacts on breeding, migrating and/or wintering shorebirds, depending on when the activities take place.

Waterfowl along the marine shoreline and inland ponds and lakes may be disturbed by noise from blasting and other construction activities. Seabirds nest on a number of offshore islands and other inaccessible coastal areas, notably the Country Island Complex, the nearest point of which is approximately 13 km from the Project site. Minor disturbance of foraging terns from blasting and other construction noise is possible; however, the distance from the colony makes it unlikely that Roseate Terns will forage in the waters near the Project. Large gulls and Common and Arctic Terns nesting on Fox Island and Half Island, both approximately 3 km from the Project site, could potentially be disturbed by blasting noise. However, this distance is

greater than the 1 km buffer recommended by Environment Canada for high-disturbance activities such as drilling and blasting.

Habitat removal and fragmentation will result in displacement of mammals from within the Project footprint. Clearing and construction activities are expected to slightly reduce the available area used by terrestrial mammals and interrupt local movement to and from adjacent areas of suitable habitat. Project related noise (including blasting) may cause mammals in immediately adjacent areas to flee temporarily.

The loss of ponds, wetlands and riparian areas in the Project area will result in habitat loss for local amphibians and turtles, and increased sedimentation from dust generated by construction may further impact aquatic habitats. Snakes may utilize much of the Project area, and will be impacted by habitat loss as well as increased fragmentation which may inhibit movement between areas of suitable habitat.

Some loss of odonate (dragonfly and damselfly) breeding and feeding habitat is expected from the loss of wetlands, ponds and riparian areas within the Project area. Dust from construction activities may contribute to sediment loading in watercourses, potentially altering aquatic habitats. Lepidopterans (moths and butterflies) will be most affected by the loss of larval food plants, which varies from species to species; adults are highly mobile and therefore able to avoid areas impacted by Project activities.

6.10 Freshwater Species and Habitats

Fish and fish habitat are valued for their ecological services as a renewable resource base, and for their economic, cultural, spiritual and ceremonial benefits. As noted above, the watercourses and lakes on the Property do not contain fish due to acidic conditions. Nevertheless, other freshwater species and habitat are important biological components of larger ecological systems and are valued by the public and First Nations.

6.10.1 Potential Environmental Effects

Project activities will remove some freshwater habitat and may indirectly affect other areas. Once quarrying ceases and the pit fills with water, the Project will ultimately create more freshwater fish habitat than currently exists on the site.

6.11 Marine Species and Habitats

Marine species and habitats are valued for their aesthetic, cultural, ecological and economic attributes by First Nations and the public at large. Marine SAR are of interest to scientists, regulators and public due to their inherent biological and cultural value and are protected under federal provincial legislation. The marine habitat in Chedabucto Bay supports productive and diverse fisheries. A number of fish species reside within the Bay, and additional species migrate from nearby water bodies to feed and spawn. Marine mammals associated with Chedabucto Bay typically include seals, whales and porpoise.

6.11.1 Potential Environmental Effects

The majority of the effects to marine species and habitat are associated with the construction and operation of the marine terminal since the construction of this feature will remove marine habitat. Construction of the marine terminal will permanently destroy approximately 1.1 ha of sea bottom habitat even as new habitat is created by the terminal foundations. To offset this habitat loss, habitat creation nearby is required by DFO. Transport of aggregate via seagoing

vessels will impact upon the marine environment through noise associated with vessel passage and potentially through accidental spills or other incidents at sea.

Potential environmental effects on marine sediment quality are described in Section 6.4 while potential effects on marine water quality are described in Section 6.6. Potential environmental effects to commercial fisheries are described in Section 6.15. Potential environmental impacts to marine SAR are described in Section 6.12.

6.12 Species at Risk

Species at Risk are identified as a VC due to their ecological role, scientific value and cultural attributes. Species at Risk may be regulated at the federal level, the provincial levels, or both. No critical habitat for any species at risk was identified on the Property.

6.12.1 Potential Environmental Effects

The direct loss of habitat used by terrestrial or marine SAR is the primary concern of this VC, although SAR may be indirectly affected through noise, light and general activity at the Property.

Two vascular plant species of conservation concern (SOCC) are known to occur within the Project footprint. Four lichen SOCC were identified on the Project site. For most terrestrial fauna SAR/SOCC (including the one mammal, fourteen bird, and one odonate), potential effects are predicted to be similar to those for terrestrial fauna as a whole (Section 6.7).

Mainland Moose

The mainland Nova Scotia population of Eastern Moose, which is listed as Endangered under the *Nova Scotia Endangered Species Act (NSES)*, could potentially be affected by the Project through:

- Loss of habitat (foraging, wintering, calving);
- Habitat fragmentation;
- Disruption of migratory routes;
- Mortality due to vehicle collisions;
- Increased poaching levels in area due to increased traffic;
- Noise disturbance; and
- Exposure to runoff from hazardous materials/contaminated soils.

Rusty Blackbird

To date, a total of fourteen bird SOCC have been reported from the Project site. Of these, a single species, the Rusty Blackbird is a SAR. This bird, which is also listed as Endangered under the *NSES*, could potentially be affected through:

- Loss of habitat (foraging, nesting);
- Habitat fragmentation;
- Disturbance from construction noise (including blasting); and
- Exposure to runoff from hazardous materials/contaminated soils.

No terrestrial herpetile SAR or SOCC are known or suspected to occur on the Black Point site. A single invertebrate SOCC species, a dragonfly known as the Spot-winged Glider was detected on the site in 2010. No freshwater flora or fauna SAR or SOCC are known or suspected to occur on the Black Point site.

Several marine fish, mammal, and reptile SAR and/or SOCC have the potential to occur within the marine footprint and immediate vicinity of the Black Point Project site. Potential effects on marine fauna SAR and SOCC are predicted to be similar to those for marine fauna as a whole, which are discussed in detail in Section 6.11.

6.13 Local Economy, Land and Resource Use

Positive economic effects of the Project will benefit local residents, local businesses in the service sector and government at the municipal and provincial levels. Improvements in the regional economy can positively affect the population size and demographics as workers move to the area, purchase real estate, goods and services, and raise families. Real estate values can also be affected by a vibrant regional economy.

The Project will require a temporary labour force during construction and a smaller but significant labour force over the long term operation of the Project. In addition to direct hires, the Project will generate employment and economic activity through contracting for goods and services.

Current on-site land uses (trapping, local tourism) will be replaced by quarrying and associated activities. Existing and planned land uses on adjacent properties or within the Affected Area may be impacted through changes to the visual or acoustic environments.

6.13.1 Potential Environmental Effects

The positive economic impacts are principally related to long term employment opportunities which typically result in amplified demand for goods and services, as well as improved tax revenues for municipal, provincial and federal governments.

One of the primary effects of the Project is to change the use of the Property from an undeveloped piece of land used occasionally for trapping and recreational activities (ATV passage and fishing in the nearshore), to a quarry that will be operated on a continuous basis, and where these current activities will be limited or no longer practical. Despite these land use changes, the current zoning reflects a long term municipal vision to promote economic development and so is compatible with the goals and objectives of the community.

6.14 Tourism and Recreation

Residents and tourists alike utilize the local terrestrial and marine landscapes for outdoor activities such as camping, hiking, fishing, boating, off-road motoring, and hunting. Tourism and recreational activities, as well as the infrastructure associated with these activities, such as accommodation, marinas, recreation centres and parks, make up the Tourism and Recreation VC.

6.14.1 Potential Environmental Effects

The presence of a quarry may influence perceptions regarding noise and changes in the visual character of the coastal landscape, resulting in changes to resource use patterns by tourists. The Project may result in restrictions to currently accessible beaches and headlands within the

property footprint but not to nearby beaches such as Gaulmans Point and the beach at Indian Cove. Additionally, there will be little to no impact to the visual site lines from Marine Drive as the entrance area will be groomed, and the surrounding trees are anticipated to remain during the life of the Project. In addition, the quarry will be topographically lower than Marine Drive.

The quarry development has the potential to affect the tourism and recreation through a decrease in wilderness/nature oriented recreation and tourism within the Project Area and vicinity due to marine vessel traffic and actual or perceived noise, dust and light from the quarry. This in turn may negatively affect revenue at local campgrounds, rental accommodations and other service providers. The quarry may also result in an increase in expenditures on tourism services through increased discretionary spending by people hired at the Project.

6.15 Commercial Fisheries

Marine commercial fisheries represent an important, sustainable resource of historical, cultural, social and economic value to local communities and First Nations. As noted, there are no *freshwater* commercial or recreational fisheries on the Property. At the same time, aquaculture is not currently practiced along the south shore of Chedabucto Bay.

The primary species harvested on a commercial basis in Chedabucto Bay south of the established shipping lanes are:

- Lobster;
- Shrimp;
- Herring, Mackerel and Squid
- Snow Crab;
- Tuna; and
- Scallop

Sea urchin, rock crab, marine plants and eels are reportedly not fished on a commercial basis at this time, although local fishermen do have licenses that permit the harvest of these species. Mackerel is the primary salt-water recreational species in the area, but catch and release recreational Bluefin tuna fishing is also popular.

6.15.1 Potential Environmental Effects

The presence and use of the marine terminal will result in limitations to lobster harvesting in the immediate area and, as a result, potential displacement into other areas of those who currently fish in the nearshore at the Black Point site. This limitation will occur for two reasons: (1) the construction of the marine terminal will remove approximately 1.0 ha of lobster habitat that is currently available for commercial exploitation, and (2) fishermen will likely steer clear of the active marine terminal for safety and out of concern for gear losses.

Potential sediment-laden water runoff from terrestrial construction activities and consequent negative effects to water quality may displace fish from the immediate near shore but is unlikely to result in their death.

The transit of empty and loaded aggregate transport vessels has the potential to interfere with other commercial fishing activities that occur in deeper water between the established shipping

lanes and the south shore of Chedabucto Bay. In addition to interference with on-going fishing, noise associated with this increased traffic may displace fish from the immediate area.

The added ship traffic may require fishermen who frequent deeper water to avoid preferred fishing grounds to accommodate Project-related ship traffic.

Accidental fuel spill or other discharges to the aquatic environment can alter water quality and physical habitat, which in turn can negatively affect life-cycle stages of commercially important species and their food supply. Accidental aggregate spills will not likely affect the commercial fishery since this material has already been washed to remove fine-grained sediment.

No underwater blasting will be required. Blasting on land is not expected to result in significant effects since blasting charges can be minimized to meet guidelines that are designed to be protective of aquatic species.

No impact is expected to the fixed berth mackerel, herring and squid trap fisheries since these berths are considerably removed from the Project site. A possible exception to this are the two mackerel traps located in Indian Cove approximately 4.0 km east of the marine terminal. Concerns have been raised by local fishermen that the marine terminal will divert mackerel from their normal coastal-hugging route that brings them into Indian Cove where the traps are located. Instead, the terminal may encourage the fish to remain offshore and travel directly from Black Point to Fox Island, rather than entering Indian Cove.

6.16 Archeological and Heritage Resources

Archaeological and Heritage Resources were identified in the EIS Guidelines as a potential VC as concerns have been raised regarding the possible existence of these resources during the public outreach phase of the environmental assessment.

A 2011 Archaeological Resource Assessment survey did not identify any archaeological or heritage resources, but potential post-European contact house foundations were identified on the Property near the coast during the 2014 Archaeological Resource Assessment.

6.16.1 Potential Environmental Effects

Although 30 m buffer zones will be left undisturbed along the coastline (thereby protecting some of these finds), much of the coastal zone inside this buffer will be built upon, thus potentially disturbing, destroying or covering over some of these resources.

6.17 Aboriginal Land and Resource Use

Aboriginal culture in the form of traditional land and resource use is practiced on a regular basis in many Nova Scotia Aboriginal communities. Traditional hunting, fishing, and plant harvesting practices are deeply rooted and highly valued in these communities. Consideration of Aboriginal interests is legislated by federal and provincial laws and listed in the EIS Guidelines issued for this Project.

6.17.1 Potential Environmental Effects

Based on the information compiled through the MEKS and findings during site visits conducted with Mi'kmaq Elders, harvesters, Chiefs, and organizational representatives, there is currently no direct Mi'kmaq use of the Project site for subsistence harvesting of food or furbearing

animals. Several Mi'kmaq communities are currently fishing marine species for livelihood purposes along the eastern shore. Of these, only the Waycobah shrimp trap fishery is operating in proximity to the Project. The Waycobah band holds the only Mi'kmaq shrimp trap license in the south side of Chedabucto Bay however this license is currently being fished by non-aboriginal license holders on behalf of the Band. No Mi'kmaq fishermen currently deploy lobster traps in the Project vicinity although they, like other LFA 31 license holders, have the right to fish anywhere within LFA 31. Potential Environmental Effects

As noted in the Mi'kmaq Ecological Knowledge Study completed for this Project, development effects may include:

1. potential disturbance of hitherto unidentified archaeological resources during the construction of the infrastructure as well as the quarry operation itself.
2. likely permanent loss of wildlife and plant resources which have been traditionally harvested within the immediate project footprint. This loss may result from the physical removal or displacement of specimens or restriction of access to potential harvesting areas.
3. potential harm or dispersing of wildlife due to noise resulting from increased human presence, traffic, blasting, and general mining activities.
4. potential disturbance or contamination of vegetation, wetlands and water bodies as a result of settlement of dust and other airborne pollutants associated with the Project. This can significantly depreciate the quality of local food and medicinal plants for human consumption as well as the quality of animal browse and water/wetland habitat.
5. potential degradation of the local marine and shoreline habitats surrounding the shipping terminal due to dust contamination, the potential for accidental aggregate spillage during loading, and possible contamination resulting from petroleum products associated with cargo vessels. However, based on the current information (section 6.17) it is concluded that the Project will not likely have a direct significant impact on Mi'kmaq livelihood fishing: the shipping route near the marine terminal has been modified to avoid preferred shrimping grounds.

6.18 Accidents and Malfunctions

The assessment of potential environmental effects resulting from accidents and malfunctions employs risk based approach that involves:

1. Identification of hazards associated with the Project infrastructure and activities to be undertaken on-site or off-site.
2. Identification of potential environmental effects or the anticipated consequences of the identified hazards by completing a qualitative risk assessment aimed and providing some perspective on the hazards and their consequences by rating the likelihood of the adverse environmental effects. This rating represents the overall assessment of significance for the potential adverse environmental effects of accidents and malfunctions.

Those hazards with the greatest potential to result in environmental effects are:

- **Structural Failures:** These include quarry pit slope failure, aggregate stockpile slope failure, processing plant/marine terminal infrastructure failure and sediment pond failure;

- **Accidents:** These include an explosives accident, marine spills, transportation accidents (including vehicle and marine collisions), hydrocarbon spills on land or in the water; and,
- **Other Malfunctions:** These include unspecified health and safety incidents, wildlife encounters and forest fires.

Each potential accident and malfunction was assessed according to likelihood of the event and given a risk rating from “negligible” to “high”. Environmental effects are assigned a magnitude rating from “low” to “extreme”. The combination of the likelihood of an event and the magnitude of its environmental effects is determined by plotting these ratings on the matrix. Increased risk is associated with accidents and malfunctions having a greater *likelihood* of occurrence and greater *magnitude* of effects. Accidents and malfunctions with an overall combined rating of greater than or equal to 4 are not considered to be significant events or consequences. The results are summarized in Table 9. The results indicate that all accidents and malfunctions described above have ratings ranging from 5 to 8. These events and their environmental effects are therefore considered not significant.

**Table 9:
Summary of Accidents and Malfunctions Assessment**

Malfunction/Accident	Key VCs Potentially Affected	Risk Rating	Magnitude Rating	Overall Rating 1 = Maximum 9 = Minimum
Quarry Pit Slope Failure	Human Health and Safety	Negligible	High	7
Stockpile Slope Failure	Human Health and Safety Surface Water Resources Terrestrial Habitat and Vegetation	Negligible	Moderate	8
Sedimentation Pond Failure	Marine and Surface Water Resources Terrestrial Habitat and Vegetation Marine Species and Habitat Species at Risk	Very Low	Low	8
Processing Plant Infrastructure Failure	Marine and Surface Water Resources Marine Species and Habitat Species at Risk	Very Low	Moderate	7
Marine Terminal Infrastructure Failure	Marine and Surface Water Resources Marine Species and Habitat Species at Risk	Very Low	Moderate	7
Terrestrial Spill	Human Health and Safety Geology, Soil & Sediment Groundwater Resources Wetlands	Low	Moderate	7
Vessel Accident/Collisions	Human Health and Safety Marine Species and Habitat Species at Risk Local Economy Commercial Fisheries	Very Low	Very High	5
Explosives Accident	Human Health and Safety Marine and Surface Water Resources Terrestrial Habitat and Vegetation Terrestrial Wildlife Marine Species and Habitat	Negligible	Moderate	8

Malfunction/Accident	Key VCs Potentially Affected	Risk Rating	Magnitude Rating	Overall Rating 1 = Maximum 9 = Minimum
	Species at Risk			
Marine Spill	Human Health and Safety Marine and Surface Water Resources Marine Species and Habitat Species at Risk Local Economy Commercial Fisheries	Very Low	Very High	6
Illegal Ballast Discharge	Marine and Surface Water Resources Marine Species and Habitat Species at Risk Local Economy Commercial Fisheries	Low	High	5
Transportation Accident	Human Health and Safety Terrestrial Habitat and Vegetation Terrestrial Wildlife	Low	Moderate	8
Forest / Site Fire	Human Health and Safety Air Quality Terrestrial Habitat and Vegetation Terrestrial Wildlife Tourism and Recreation Aboriginal Land and Resources Use	Negligible	High	7

6.19 Effects of the Environment on the Project

The natural environment has the potential to adversely interact with the Project through meteorological, climatological and seismological events. These events may include:

- Drought or extreme precipitation events leading to flooding;
- Extreme (high/low) temperatures;
- Rapid or increasing number of freeze/thaw events;
- Severe wind storms including hurricanes;
- Extreme marine conditions (high waves plus extreme winds);
- Ice storms and hail events;
- Late season sea ice; and
- Earthquakes.

The Project is located on a relatively exposed southern coastline exposed to northerly winds and considerable wave action. Initial designs have considered prevailing historical conditions, including extreme events, as well the anticipated effects of climate change on key weather variables. As the Project moves into the detailed design stage, additional consideration will be given to the effects of the environment on the Project.

In addition to design factors, potential adverse effects on the Project due to the environment will be mitigated through the monitoring and/or contingency planning. Therefore, the effects of the environment on the Project are anticipated to be not significant.

6.20 Cumulative Effects

Cumulative environmental effects are residual Project effects combined with the environmental effects of past, present, and future projects. For this assessment, the descriptions of the existing environment and of the current condition of each VC already include the effects of current projects occurring within or outside of the Project Area. The cumulative effects assessment thus focuses on the effects of other future projects and activities.

With respect to identifying potential cumulative effects:

1. there must be a measurable environmental effect of the project being proposed;
2. the environmental effect must be demonstrated to interact cumulatively with the environmental effects from other projects or activities; and
3. it must be known that the other projects or activities have been, or will be, carried out and are not hypothetical. That is, there must be some *probability* the cumulative environmental effect will occur rather than simply a *possibility*.

Based on these parameters, four projects were identified as potentially contributing cumulative effects to the Black Point Quarry Project:

Chedabucto Aggregates Quarry Expansion (Halfway Cove, Guysborough Co.)

Chedabucto Aggregates Limited in September 2014 indicated they will register the Chedabucto Aggregates Quarry Expansion for environmental assessment. The project is located approximately 13 km southeast of Guysborough. The proposed expansion is scheduled for 2015; production levels and operations are not expected to increase as a result of the proposed expansion.

Goldboro Liquefied Natural Gas Project (Goldboro, Guysborough Co.)

Pieridae Energy proposes to construct a natural gas liquefaction plant and marine terminal in Goldboro, Guysborough County. On March 21, 2014 the project was approved with conditions and the project is currently in the Front End Engineering and Design phase.

Maher Melford Container Terminal (Melford, Guysborough Co.)

Melford International Terminal is proposing to develop a 315-acre container terminal and intermodal rail facility in Melford on the Strait of Canso. In late 2014 the Nova Scotia Minister of the Environment authorized an extension for the commencement of project work: the Proponent must, on or before October 23, 2016, commence work on the project unless granted an extension by the Minister.

Bear Head Liquefied Natural Gas Project (Port Hawkesbury, Cape Breton)

The Bear Head project near Port Hawkesbury received EA approval in 2004. Construction on the LNG facility began in 2005, but later ceased. In July 2014, the company Liquefied Natural Gas Ltd. announced it has purchased the project. In November 2014, Liquefied Natural Gas Ltd. announced plans to double the capacity of the proposed liquefaction and export terminal from 4 mtpa to 8 mtpa. A final investment decision on the Bear Head project is expected in late 2015 to 2016 and the facility could be in commercial operation in late 2018 to 2019.

In order to identify potential overlapping projects and systematically assess the likely cumulative effects for each VC, the Project team:

1. Researched the status of future planned or anticipated projects that could overlap in time or space with the Project; and
2. Defined the spatial and temporal boundaries that would be used to assess the degree and significance of the overlap (i.e., the cumulative effect) for each VC.

All VCs were examined for the potential to contribute to cumulative effects. Once future projects were identified, the infrastructure and activities associated with these projects were reviewed to determine the likelihood that potential effects on VCs at these projects would overlap in space with the VCs assessed for the Black Point Project. If an effect was likely, then these effects were further examined as to their potential to overlap in time (temporal overlap) with Black Point effects.

Chedabucto Aggregates quarry is located approximately 17 km west of Black Point. Given the distance from the Project Area and the limited scale of quarrying activities associated with the expansion, no overlap in space between the environmental effects produced at Chedabucto Aggregates and the Black Point Project is expected. Therefore, no cumulative effects are anticipated.

The Goldboro LNG project is located on Nova Scotia's eastern shore, approximately 45 km southwest the Black Point Project. The project is associated with a number of residual environmental effects but most of these effects are not considered to be significant. The project's GHG emissions could be regionally significant when combined with other large, regional GHG emitters, but the Black Point Project is not a significant GHG producer. Vessel traffic to the Goldboro marine terminal will remain many kilometres from Chedabucto Bay. Under these circumstances, there is no overlap in space between the effects produced at Goldboro and those expected at Black Point. Given this, no cumulative effects are anticipated.

Given their relative proximity and location with respect to the Black Point Project site, certain aspects of the Bear Head LNG and the Maher Melford Container Terminal projects are expected to overlap in space and time with VCs retained for the Black Point Project. These VCs include:

- Shipping and Navigation
- Local Economy, Land and Resource Use

With respect to Shipping and Navigation, the vessels used to transport aggregate will not be operated by Proponent crews and so mitigation of potential vessel collisions is, to a large extent, outside of the control of the Proponent. Nevertheless, the Proponent will review the safety and environmental records of shipping contractors prior to engaging them, with the aim of employing only the most reputable firms.

Marine traffic within Chedabucto Bay managed by the Canadian Coast Guard and the Proponent will communicate with the MCTS to the extent requested or required during adverse weather conditions. To the extent applicable, the Proponent will also

- Comply with the Eastern Canada Vessel Traffic Services Zone Regulations of the *Canada Shipping Act*;

- Comply with navigational and operational requirements of Atlantic Pilotage Authority and Coast Guard; and
- As needed, provide marine vessel volumes and schedules to marine management operators responsible for traffic movement; and

With respect to Local Economy, Land and Resource Use the Proponent is committed to meeting with local schools, trade unions and other organizations to describe labour and skill requirements, and to employ a procurement policy that favors local labour markets and suppliers.

Taking into account the basic mitigation measures described above, the residual adverse cumulative effects expected with respect to Shipping and Navigation are predicted to be insignificant. Cumulative effects to the Local Economy, Land and Resource Use are expected to be positive and potentially significant over the medium to long term.

6.21 Changes and Effects of Changes Under Federal Jurisdiction

As noted in Section 3.1.3, this section summarizes changes to components of the environment within federal jurisdiction; changes to the environment that would occur on federal or transboundary lands; changes to the environment that are directly linked or necessarily incidental to federal decisions; effects of changes to the environment on Aboriginal peoples; and the effects of changes to the environment that are directly linked or necessarily incidental to federal decisions.

Changes to Components Within Federal Jurisdiction

- Changes are expected to freshwater fish habitat in Reynolds Brook where reductions in flow of up to 18% may be expected in the brook section above Hendsbee Lake. Water quality improvements may also occur due to the reduced inflows of low pH water.
- Changes are expected to marine fish and fish habitat, including marine plants due to the construction of the marine terminal and the transit of marine vessels to and from the terminal.
- Changes to migratory bird behaviour and risk of mortality may occur due to light and noise associated with the Project.

Changes to the Environment Occurring on Federal or Transboundary lands;

The marine components of the Project, especially aggregate shipping, have the potential to result in changes to the environment on federal submerged lands and federal waters. No changes are anticipated on federally owned or federally managed terrestrial lands.

Changes to the Environment that are Directly Linked or Necessarily Incidental to Federal Decisions

A *Navigation Protection Act* approval and *Fisheries Act* authorisation will be required to construct the marine terminal. As a result of these approvals, changes in the marine environment may include effects on marine fish and fish habitat and commercial lobster and shrimp fishing.

Effects of Changes to the Environment on Aboriginal Peoples

The site is not currently visited for resource harvesting and there are currently no FSC fisheries at the Project site. Changes to the environment will not negatively affect health and socio-economic conditions (positive economic benefits may be realised), physical and cultural heritage, the current use of lands and resources for traditional purposes, or any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.

Effects of Changes to the Environment Directly Linked or Necessarily Incidental to Federal Decisions

As noted a *Navigation Protection Act* approval and *Fisheries Act* authorisation will be required to construct the marine terminal. The marine terminal is not expected to result in adverse effects to health, physical and cultural heritage, or any structure, site or thing that is of historical, archaeological, paleontological or architectural significance. In contrast, effects on socio-economic conditions may result from the terminal's effect on the commercial fisheries through:

- Change in risk of fish injury or death; and
- Change in fish or other habitat quality and use;

These potential changes are expected to be temporary and confined to the area around the marine terminal and to the designated shipping routes between the terminal and the main shipping lanes in Chedabucto Bay. With the implementation of the proposed Fisheries Offset Plan, these effects are not expected to significantly alter the socio-economic conditions for commercial or Aboriginal fishermen.

7.0 MITIGATION AND MONITORING MEASURES

The Proponent has committed to a number of mitigation measures to limit or eliminate adverse environmental effects and monitoring programs to verify predictions made in the environmental assessment. Table 10 summarizes the mitigation measures on a VC by VC basis, and lists the proposed follow and monitoring programs.

**Table 10:
Proposed Mitigation Measures and Monitoring Programs**

VC	Mitigation	Monitoring
Air Quality and Climate Change (7.1)	<ul style="list-style-type: none"> • Regular maintenance of all equipment and emission control devices. • The use of wet suppression and/or dust collection systems on crushers, screens, and conveyor transfer points. Some parts of the process due to high moisture content of the stone will not need water sprays or additional dust control. • The application of water to the access and haul roads and aggregate stockpiles as needed. • Use of qualified blasting contractors with blast design plans that incorporate dust emission controls. • Construction of the haul roads using material with low silt content. • Use of a binder substance within the dust suppression application (e.g. calcium chloride) during drier periods of the year to aid in keeping the roads moist for longer periods of time, when necessary.. • Use adaptive management to adjust dust control measures and/or operating conditions to account for changing conditions that affect dust control. Some of the control measures that will be implemented based on management determination of need include: <ul style="list-style-type: none"> ○ Increase in watering frequency of haul roads and stock piles. ○ Application of dust suppressants to the haul and access roads. ○ Reduction in allowable speed on haul and access roads. ○ Restriction or suspension of operation of part or all of the processing plant until dust can be controlled. ○ Suspension or modification of overburden handling activities. ○ Addition or modification of dust suppression systems to address specific points where dust is being generated, including spray nozzle additions and/or modifications. ○ Modify operation and dust controls during high wind events (>30 km/h) to control dust, if it cannot be controlled suspend operation until it can. • Utilize multi-passenger vehicles to transport crew when possible. • Use high quality, ultra-low sulphur diesel fuels or standard unleaded gasoline for mobile equipment at the operation. (Note: Ships will not be refuelled at the site; vessel fuel type is not within the Proponent's control). • Reduce idling and shut off equipment when parked unless it is required to operate due to safety considerations, inspection requirements or maintenance activity. 	<ul style="list-style-type: none"> • Daily dust and weather monitoring as described in the Environmental Management Plan. • Regular individual worker / workplace health and safety testing. • Agency-requested ambient air quality testing or monitoring as required. • Implementation of a complaints log / response protocol at the site office.

VC	Mitigation	Monitoring
Noise and Vibration (7.2)	<ul style="list-style-type: none"> • Turn off equipment that is idling and not in use. • Utilize drill rig that has dust suppression incorporated into its design. • Apply water to shot rock pile as needed to reduce emissions from loading and conveyance of material to the process. • Ships must comply with International Marine Organization limits on NO_x, VOC, and SO₂ but enforcement is the responsibility of Transport Canada. • Optimize load times to limit auxiliary engine idling on ships at dock. • Procure equipment that meets best practices in terms of noise emissions. • Place as much distance as possible between the plant or equipment and residences. • Maximize shielding from quarry walls, buildings and stockpiles as noise barriers. • Use natural landforms as noise barriers. • Include in tenders, subcontractor agreements and work method statements clauses that assure the minimization of noise and compliance with directions from management to minimize noise. • Regularly train workers and contractors to use equipment in ways that minimize noise. • Ensure that site managers periodically check the site, nearby residences and other sensitive receptors for noise problems. • Procure equipment that meets US EPA Category IV air emission standards for off-road diesel equipment which tend to generate less noise than older equipment. • Equipment that operates in the quarry pit should stay in the pit to the extent possible so that the pit walls attenuate the noise levels. • Locate product stockpiles and other structures to the extent possible to attenuate the noise from the processing equipment. • Restrict operating hours for the quarry and processing plants to 16-hours per day so that noise levels are reduced during night time. • Restrict blasting to daytime hours and weekdays • Keep truck drivers informed of designated vehicle routes, parking locations, acceptable delivery hours and other relevant practices (e.g. minimizing the use of engine brakes and engine idling). • Minimize the use of reversing alarms by designing the site layout to avoid reversing. • Provide information/advance notification to neighbors before and during construction through media such as letterbox drops or meetings; • Upon request, residents will be alerted to upcoming production shots (blasts) via automated telephone notifications ("robo-calls"). <p><u>Night-time Mitigation Measures</u></p> <ul style="list-style-type: none"> • Minimize the need for reversing alarms. 	<ul style="list-style-type: none"> • As required by the NSE Pit and Quarry Guidelines, all blasts will be monitored to establish concussion and vibration levels. This is consistent with the Proponent's standard operating practices at all quarries. • As required by NSE, sound level monitoring will be undertaken at the property boundary or elsewhere as directed during daytime, evening and night-time to verify compliance with the Pit and Quarry guidelines. • As part of the workplace health and safety program, noise monitors will be attached to workers on a regular basis to measure and monitor noise exposure over an eight hour shift.

VC	Mitigation	Monitoring
	<ul style="list-style-type: none"> • Avoid metal-to-metal contact on equipment. • Ensure that periods of respite are provided in the case of unavoidable maximum noise level events. 	
Ambient Light (7.3)	<ul style="list-style-type: none"> • Use full cut off luminaires where no light is emitted above the horizontal plane, where practical and where they don't comprise worker safety. • Use only the lights needed to meet local lighting objectives. • Where practical Minimize glare by keeping the main beam angle less than 70 degrees. • Use floodlights with asymmetric beams where possible. • Direct the site lighting away from residential properties. • Where possible position lights as far away from site boundaries as practical. • Where possible, keep lighting at low heights to reduce the chance of illuminating migrating birds. • Pole mounted lighting will be pointed downward and shielded from the top and sides. • To the extent possible, low intensity lighting will be used rather than high intensity lighting. • Lights placed on the outside of the quarry work areas will be kept as low as possible and correctly aimed to prevent lighting non-essential areas. • Lights for the marine terminal will be chosen and aimed to prevent where possible light shining directly into the water. • Marine terminal lighting will be controlled so that minimal lighting will be used when the terminal is not in operation. • If lighting is required at the perimeter of the site it will be aimed inward to prevent off site light trespass. • Temporary lighting used during construction will be focussed on the intended work area and will be shielded to minimize spillage. • To reduce night time ambient lighting effects, operations will be routinely monitored so that lighting can be switched off by work area when it is not needed. • Consideration will be given to using light sources such as directional LEDs to give a better spread of lighting and reduce the overall intensity of the lighting systems. • Consideration will be given to selecting lights that have a lesser effect on the wildlife to help reduce lighting effects on nocturnal species. 	<ul style="list-style-type: none"> • Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. • The Environmental Management Plan will include instructions on implementing the protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) for responding to avian strandings related to activities in the marine environment. • Nightly site inspections will reveal opportunities for light reduction
Geology, Soil & Sediment Quality (7.4)	<ul style="list-style-type: none"> • Standard mitigation measures to manage acid generating rock, including the control and containment of drainage and the management of excavated rock as per NSE regulation. • Sloping of the processing plant area to the south to collect surface water within the sedimentation ponds, prevent discharge to the ocean. • Environmental Management Plan that describes standard ARD control measures. The 	<ul style="list-style-type: none"> • The acid generating potential of bedrock will be assessed at the beginning of construction as per the <i>Nova Scotia Sulphide Bearing Material Disposal Regulations</i>. • Discharge will be monitored through a Surface Water Monitoring Program elaborated within the Environmental Management Plan.

VC	Mitigation	Monitoring
	Environmental Management Plan will incorporate an Erosion and Sediment Control Plan to ensure drainage is properly managed and control structures inspected and a Stormwater Management Plan that describes the construction and operation drainage swales and stormwater management ponds.	
Groundwater Resources (7.5)	<ul style="list-style-type: none"> • Since no impacts to groundwater users are expected, no mitigation is proposed • To mitigate reductions in groundwater flows that supply nearby wetlands, implement a Wetland Compensation Plan for wetlands damaged due to the Project. 	<p>The groundwater wells will be monitored as part of the Groundwater Monitoring Program elaborated within the Environmental Management Plan.</p>
Marine and Surface Water Resources (7.6)	<ul style="list-style-type: none"> • Sedimentation ponds will be used near the processing plant while the quarry pit will employ sumps to collect water inflows. • Topographic controls (sloping the ground to the south) will ensure that overflow, should it occur, will collect against the south cliff and in the pit, rather than be permitted to discharge directly to the ocean. • Double walled and or/fully bermed fuel and chemical storage reservoirs will be used. • The Environmental Management Plan will include a discrete Erosion and Sediment Control Plan to ensure drainage is properly managed and control structures inspected and a Stormwater Management Plan that describes the construction and operation drainage swales and stormwater management ponds. • The EMP will also include an Emergency Response and Spill Contingency Plan combined with incident prevention and emergency response training to minimize the risk of accidental spills and to rapidly react to any incident that may occur. The Emergency Response and Spill Contingency Plan will include spill dispersion modelling in the marine environment to aid in rapid and effect emergency response. • The Proponent will contract with a local emergency response consultant to ensure that additional resources and expertise are available in the event of an accidental spill in the marine environment. • To mitigate reductions in surface water flows that supply nearby wetlands, implement a Wetland Compensation Plan for wetlands damaged due to the Project. 	<ul style="list-style-type: none"> • Discharge will be monitored through a Surface Water Monitoring Program elaborated within the Environmental Management Plan. • The success of the Wetland Compensation Plan will be monitored over time as determined in collaboration with NSE; other water features not directly included in the Plan will be inspected to detect hydrological changes potentially caused by the Project – these inspections will be outlined in the Plan.
Terrestrial Ecosystems, Habitat and Vegetation (7.7)	<ul style="list-style-type: none"> • A general set of environmental mitigation measures will be defined in the Environmental Management Plan which will include an Erosion and Sediment Control Plan, a Stormwater Management Plan and an Emergency Response and Spill Contingency Plan. • Minimize the Project footprint. • Mark Project boundaries to prevent accidental impacts outside the work area. • Remove/ and salvage topsoil; store separately and reuse for site restoration. 	<ul style="list-style-type: none"> • The Environmental Management Plan will establish monitoring/inspection plans to ensure protective mitigation measures are implemented and effective. • Daily inspection and record keeping will be described in the EMP.

VC	Mitigation	Monitoring
	<ul style="list-style-type: none"> • Dust-prevention and abatement measures outlined above will also protect local flora and habitats. • Stabilize and rehabilitate areas of disturbance. • Use local native vegetation in restoration; consideration will be given to the preferential use of vegetation types of interest to the Mi'kmaq. • Vegetation management will be conducted by mechanical cutting (e.g., mower, brush cutter); • Mitigation measures for the protection of watercourses (see Section 7.6 and 7.10) will help to protect terrestrial and freshwater aquatic vegetation and habitats. 	
Wetlands (7.8)	<ul style="list-style-type: none"> • Mitigation developed for surface water quality will also protect wetlands (Sections 7.6). • Mitigation against the potential effects of spills, malfunctions and accidents are described in Section 7.18. • Wetlands will be avoided to the extent feasible during Project planning. • Where wetlands cannot be avoided, the Project footprint in the wetland area will be minimized. • A wetland alteration permit will be obtained from NSE prior to construction. • Where a permanent loss of wetland function is identified, a Wetland Compensation Plan will be developed, subject to approval by NSE. • Maintain a 30 m buffer around all undisturbed wetlands. • Where the access road cuts across diffuse natural drainage paths culverts or drainage swales of sufficient size will be installed to maintain water flow at pre-construction levels. • To the extent feasible, clean site runoff will be managed so that the amount of water entering adjacent wetlands is similar to pre-construction levels. • Runoff collected along the roads will not be allowed to enter directly into wetlands, but shall be directed into vegetation buffers around wetlands. • Integration of existing/remnant wetlands into the quarry's stormwater management system will be considered in the Stormwater Management Plan and in the Environmental Management Plan. • Implement Erosion and Sediment Control Plan. • Uncontaminated drainage will be directed away from areas under construction. • Vegetation management in or near wetlands will be conducted by cutting (i.e., no use of herbicides). • Dust-prevention and abatement measures outlined above will also protect wetlands. 	<ul style="list-style-type: none"> • Efficacy of the erosion and sediment control measures will be monitored as outlined in the Environmental Management Plan. • Monitoring of new or enhanced wetlands will be undertaken as per the Wetland Compensation Plan. • Other water features not directly included in the Plan will be inspected to detect hydrological changes potentially caused by the Project – these inspections will be outlined in the Plan.
Terrestrial Wildlife (7.9)	<ul style="list-style-type: none"> • Minimize the Project footprint. • Implement dust-prevention and dust abatement measures described above. • Implement a Wetland Compensation Plan. • Instruct workers to maintain good housekeeping practices and not leave out any food or garbage to avoid attracting wildlife. 	<ul style="list-style-type: none"> • Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. • The Environmental Management Plan will include provisions describing specific management actions for at risk species (e.g.,

VC	Mitigation	Monitoring
	<ul style="list-style-type: none"> • To minimize impacts on nesting landbirds, clearing will take place outside of the breeding season for most bird species (April 1 to September 1). If some clearing is necessary during the breeding season the Proponent will assess if the work can be undertaken without contravention of the <i>Migratory Birds Convention Act</i> and a contingency plan developed in consultation with CWS in order to maintain compliance with the Act. • If an Osprey, Bald Eagle or Northern Goshawk nest is found, even outside of the breeding season, a buffer zone will be placed around the nest and clearing will only occur outside of the buffer zone. • To discourage ground-nesting or burrow-nesting species, no large piles or patches of bare soil will be left uncovered or un-vegetated during the breeding season. • Should any ground- or burrow-nesting species initiate breeding activities on stockpiles or exposed areas, the Proponent will establish a 20 m buffer around the nest location and contact EC-CWS for further advice. • Noise suppression equipment such as mufflers on mobile equipment and fixed/portable engines will be maintained in original OEM working condition • The duration of noise disturbance will be minimized. • Lighting will be restricted to areas where it is necessary. • To minimize interference of nesting activities, workers will be asked to refrain from entering undisturbed habitat areas where no work is done. • In the event that impacts on migratory birds are detected during construction, further mitigation will be developed in consultation with NSDNR and EC. • Standard mitigation measures for noise (including blasting), as outlined in Section 7.2, will minimize impacts on terrestrial fauna. • As recommended by EC, ships en route will maintain a minimum distance of at least 300 m from any colony or island occupied by seabirds and waterbirds. • To minimize the risk to migrant birds, the minimum amount of pilot warning and obstruction avoidance lighting will be used on tall structures. • Lighting for the safety of the employees should be shielded to shine down and only to where it is needed, without compromising safety. • Street and parking lot lighting should also be shielded so that little escapes into the sky and it falls where it is required. • The protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) will be used for stranded seabirds. • White lights will be preferred for use on towers or high structures at night, as recommended by the US Fish and Wildlife Service (2003). Solid red or flashing red lights will be avoided as they appear 	Mainland Moose, ground- or burrow-nesting species)

VC	Mitigation	Monitoring
	<p>to attract nocturnal migrants more than white flashing lights.</p> <ul style="list-style-type: none"> • The operation of exterior decorative lights such as spotlights and floodlights, whose function are to highlight features of buildings or to illuminate an entire building, will be avoided unless safety is a factor. • High intensity lights, including floodlights, will be turned off at night outside of working hours, if possible, especially during the spring and fall migration period. • Where feasible, tinted or frosted glass windows will be used in buildings to reduce bird mortality from collisions. 	
Freshwater Species and Habitat (7.10)	<ul style="list-style-type: none"> • As described in the Erosion and Sediment Control Plan, erosion control measures will be implemented to ensure that discharge water quality meets all relevant regulatory standards prior to discharge to receiving environment. • As described in the Stormwater Management Plan, stormwater will be collected in the pit and in ponds near the processing plant to ensure that uncontrolled runoff will not occur. • Overburden stockpiles, fuel and chemical storage facilities, and construction equipment will be located a minimum of 30 m from any pre-development water body. • Flagging tape will be used to delineate temporary work areas and control construction access near retained wetlands and water bodies to protect natural substrates and vegetation contributing to habitat and bank stability; • An Emergency Response Spill Contingency Plan will be prepared to prevent and manage the effects of any malfunctions and accidents. 	<ul style="list-style-type: none"> • Fish habitat assessment and determination of presence/absence is proposed for Reynolds Brook above Hendsbee Lake. If fish are present, then a modest monitoring program is proposed for such time as quarry development begins to divert water away from its natural drainage to the south. This is not expected to occur before year 10 of quarry development. <p>During construction and operation monitoring will focus on:</p> <ul style="list-style-type: none"> • Condition and location of erosion and sediment control structures; • Water quality testing of stormwater discharge as outlined in the Surface Water Monitoring Program; <p>Ensuring overburden stockpiles, fuel and chemical storage facilities,</p> <ul style="list-style-type: none"> • and construction equipment are a minimum of 30m from any natural water body.
Marine Species and Habitat (7.11)	<ul style="list-style-type: none"> • An Environmental Management Plan will describe the following preventative and mitigation measures: <ul style="list-style-type: none"> ○ Application of appropriate timing windows for all in-water work. ○ Implementation of terrestrial erosion and sediment control measures. ○ Use of surface water monitoring to ensure that quality meets all relevant regulatory standards prior to discharge to receiving environment. • Install overburden stockpiles, fuel and chemical storage facilities a minimum of 30 m from Chedabucto Bay. • Implement an Emergency Response and Spill Contingency Plan for Accidents and Malfunctions. • If effects from blasting vibrations exceed the DFO thresholds, then a site specific standard to protect fish and an appropriately scaled fish and fish habitat offset plan will be implemented. 	<ul style="list-style-type: none"> • Fisheries Offset Program and associated monitoring for effectiveness. • Concussion and ground vibration monitoring during each blast to ensure limits established by DFO for the marine environment are respected.

VC	Mitigation	Monitoring
	<ul style="list-style-type: none"> Control ballast water release via “<i>Ballast Water Control and Management Regulations</i>” and the requirements as per the International Convention for the control and Management of Ship’s Ballast Water and Sediments. Equip the ship loader with aggregate spill containment features. Implement a Fisheries Offset Program to recreate fish habitat that has suffered “serious harm”. 	
Species at Risk (SAR) and of Conservation Concern (SOCC) (7.12)	<ul style="list-style-type: none"> Mitigation for potential effects on SAR and SOCC are similar to recommendations for terrestrial or marine fauna as a whole. Standard mitigation measures such as minimization of Project footprint, dust control, emissions control, and monitoring of air quality targets as detailed in Sections 7.7 and 7.1 will be sufficient to protect many SAR and SOCC, if present. Standard handling and storage procedures for hazardous material, as well as procedures for handling and disposal of contaminated soils (outlined in Section 7.18), will adequately mitigate the potential for exposure of Moose and bird SAR/SOCC to any hazardous materials or contaminated soils. Strict reporting policies for any suspected hunting activities will help to minimize any potential Moose poaching in the Project area. Imposing a 50 km/hr speed limit will reduce the potential for vehicle-moose collisions. It will also decrease encounters between humans and Moose. Exposed soils and soil stockpiles will be adequately covered or vegetated to deter Common Nighthawks from nesting on them. Should Common Nighthawks initiate breeding, the Proponent will establish a 20 m buffer around the location once identified, and contact CWS for further advice. 	<ul style="list-style-type: none"> Mainland Moose surveys (presence/absence and use) will be performed annually for up to three years after construction is initiated. Regular inspections for Common Nighthawk nests.
Local Economy, Land and Resource Use (7.13)	<ul style="list-style-type: none"> Recreational users will be notified of restricted access by signage at the entrance to the construction site. Vessels will not be refuelled at the marine terminal and fuel used at the quarry will be kept in double hulled reservoirs or will be placed within secondary containment and will be protected against collision. This helps to minimize the risk of accidents at the terminal. Navigational safety mitigation measures and emergency response planning measures are presented in Section 7.18.3. As part of the Environmental Management Plan, implement an Emergency Response and Spill Contingency Plan in advance of any accident or malfunction causing a spill in the marine environment. The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed. 	<ul style="list-style-type: none"> None proposed
Tourism and	<ul style="list-style-type: none"> Recreational users will be notified of restricted access by signage at the entrance to the 	<ul style="list-style-type: none"> None proposed

VC	Mitigation	Monitoring
Recreation (7.14)	<p>construction site.</p> <ul style="list-style-type: none"> • Vessels will not be refuelled at the marine terminal and fuel used at the quarry will be kept in double hulled reservoirs protected against collision. This helps to minimize the risk of accidents at the terminal. • Navigational safety mitigation measures and emergency response planning measures are presented in Section 7.18.3. • As part of the Environmental Management Plan, implement an Emergency Response and Spill Contingency Plan in advance of any accident or malfunction causing a spill in the marine environment. • The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed. 	
Commercial Fisheries (7.15)	<ul style="list-style-type: none"> • Minimize the impact of construction in the marine environment during and after lobster fishing season to the extent possible. For example: standard construction best management practices and mitigation measures to control onshore sediment release to the marine environment will be implemented (Section 7.6 and Section 7.11). • The quarry site office will be manned 24 hrs/day so that fishermen can telephone to receive information regarding vessel arrival and departures. The phone number can also be used to report loss or damage to gear caused by Project-related vessel traffic. • Construction and regular use of the marine terminal will require a safety exclusion zone around the terminal. Loss of these fishing grounds will be mitigated through the creation of new lobster habitat as described in the Fisheries Offset Program to be established in collaboration with local fishermen and DFO. • Routine communication with potentially affected Mi'kmaq will occur through the CLC to which they have been invited to sit as members or through other means as established by both parties. 	<ul style="list-style-type: none"> • Monitoring terminal operations and fishing access in response to concerns expressed by local fishing community, as needed; • Monitoring of the effectiveness of the marine Fisheries Offset Program for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met.
Archaeological/Heritage Resources (7.16)	<ul style="list-style-type: none"> • Prior to construction, implement a Cultural Resource Management Plan to guide site personnel in the event that archaeological and heritage resources are identified during construction. The Plan specifies a notification procedure if remains are found, and will describe specific preservation measures as needed. • These mitigation measures would be approved by the Minister of the Department of Communities, Culture and Heritage before site construction could begin. • Exploratory excavation will likely be required in those areas that may be disturbed during Project construction. 	<ul style="list-style-type: none"> • Follow up pre-construction excavation to investigate heritage resources that will be lost during project construction • Monitor construction activities near known or suspected cultural resources.
Mi'kmaq Land and Resource Use	<ul style="list-style-type: none"> • While there is currently no Mi'kmaq harvesting on the site or in waters immediately adjacent, it is intended that the non-hazardous portions of the Project site and adjacent waters will be accessible 	<ul style="list-style-type: none"> • Monitoring of progress and implementation of MOU and any other agreements reached with other First Nation communities.

VC	Mitigation	Monitoring
(7.17)	<p>to Mi'kmaq for harvesting for flora and fauna for food, social and ceremonial purposes, to the extent this is not precluded by safety consideration</p> <ul style="list-style-type: none"> Any future potential Project impacts (environmental, social and economic) on these harvesting activities will be a matter of the formal and regular meetings with the Mi'kmaq community representatives. In the event that archaeological remains are excavated, recommended guidelines as directed by the Nova Scotia Communities, Culture, and Heritage Coordinator of Special Places will be employed. Should evidence of aboriginal archeological remains be uncovered all activity will cease until Mi'kmaq archaeological experts have had an opportunity to examine the site and determine appropriate action. 	<ul style="list-style-type: none"> Mi'kmaq resource harvesting activities will be reviewed with Mi'kmaq representatives at the Community Liaison Committee meetings.

8.0 PROPOSED SIGNIFICANCE DETERMINATION

Thresholds are used to define a level beyond which a residual environmental effect (i.e., an effect that remains after the application of mitigation measures) would be considered significant or unacceptable. These thresholds are based on applicable regulation, if available, or on standards, resource management objectives, or the preservation of ecological sustainability. VC-specific significance thresholds defined for the Black Point Project are given in Table 11, which also demonstrates that no significant residual environmental effects are expected.

Table 11:
Residual Adverse Effects, Significance Thresholds and Significance

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
Air Quality and Climate Change		
Fugitive dust emissions from site preparation, quarrying, crushing, stockpiling, vehicle traffic and off loading	An exceedance of the Nova Scotia or CCME ambient air quality standards at a residential or commercial location outside the property boundary, where the exceedance is due to emissions from the operation and the event occurs more than twice in the period of time that the standard is based	Not Significant
Emissions of fuel combustion products from site vehicles and generators	As above	Not Significant
Noise (Terrestrial)		
Ambient noise perceived by residents living around the site during construction (road building, vehicle traffic, blasting, crushing, marine terminal construction)	An exceedance of the maximum noise or vibration limits listed in the <i>Pit and Quarry Guidelines</i> at or beyond the property boundary, where the exceedance is due to noise from the operation and the event occurs more than twice in the period of time that the standard is based.	Not Significant
Ambient noise perceived by residents living around the site during operation (blasting, loading, crushing, screening, offloading)	As above	Not Significant
Ambient Light		
Increased ambient light from the Project construction and operation, including operation of the marine terminal	Direct light trespass that according to the affected resident regularly interferes with the use and enjoyment of nearby residential properties on a permanent basis.	Not Significant
Attraction or disturbance of nocturnal wildlife and/or migrating birds	Evidence of unacceptable levels of bird mortality associated with Project lighting (mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds).	Not Significant
Geology, Soil and Sediment Quality		
Surface water discharge to the marine environment	An accidental release of low pH, acid rock drainage to the marine environment.	Not Significant
As above	An accidental release of total suspended solids in	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
	excess of the maximum values listed in the CCME (1999) Water Quality Guidelines for the Protection of Aquatic Life (Marine) and/or the Nova Scotia Pit and Quarry Guidelines (NSEL 1999).	
Groundwater Resources		
Reduction in groundwater recharge to offsite surface water features; changes to groundwater quality	A decrease in groundwater supply to Adjacent Areas by 20% and/or an impairment in water quality such that groundwater discharge to surface waterbodies no longer meets Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 1999 as updated).	Not Significant
Marine and Surface Water Resources		
Changes to surface water quality	Discharge from the site exceeds the liquid effluent discharge standards in the <i>Pit and Quarry Guidelines</i> (NSEL 1999) or criteria listed in the CCME <i>Canadian Water Quality Guidelines for the Protection of Aquatic Life</i> , both freshwater and marine (CCME 1999).	Not Significant
Effects on Reynolds Brook and Murphys Lake from diversion of surface and groundwater into the pit over time	A predicted change in the mean annual runoff within any off-site watercourse, or flow into any water body which changes by 20%. A predicted change in peak flow of water discharged from the site which will measurably increase the risk of flooding to downstream watercourses	Not Significant
Terrestrial Ecosystems		
Habitat loss / plant mortality	A decline in abundance and/or a change in distribution beyond which natural recruitment would not return the population to its pre-project level within several (3-5) generations.	Not Significant
Wetlands		
Progressive habitat loss due to Project construction and operation over 50 years	An effect that is likely to cause a permanent net loss of wetland function as established during the wetland evaluation.	Not Significant following compensation
Changes to wetland hydrology and water quality resulting in habitat loss	As above.	Not Significant
Terrestrial Wildlife		
Habitat loss / fragmentation	An effect that causes a decline in abundance and/ or a change in distribution beyond which natural	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
	recruitment would not return the population to its pre-project level within several (three to five) generations	
Wildlife disturbance	As above	Not Significant
Disturbance of seabirds and waterfowl	As above	Not Significant

Freshwater Species and Habitat

Effects on Reynolds Brook from diversion of surface and groundwater into the pit over time	A permanent, irreplaceable loss of Freshwater Species and Habitat that are part of or support a commercial, recreational or Aboriginal fishery.	Not Significant
--	---	-----------------

Marine Species and Habitat

Temporary noise and vibration effects to marine biota	<ol style="list-style-type: none"> 1. Adverse and irreversible changes to critical habitats; 2. Serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or to fish species that support such a fishery; 3. Permanent impairment of the ecological functioning of the biotic community; and/or 4. Increased ecological risk to a level that long term effects to the health of aquatic biota is predicted. 	Not Significant
Permanent loss of habitat resulting from the construction and operation of the marine terminal	As above	Not Significant following Offset

Species at Risk (SAR)

Terrestrial Flora and Fauna SAR/SOCC - Clearing and site preparation will result in habitat loss and fragmentation and SOCC plant mortality	An effect that causes a decline in abundance and/ or a change in distribution beyond which natural recruitment would not return the population to its pre-project level within several generations and/or an adverse effect that causes a net loss of habitat function	Not Significant
Terrestrial Fauna SAR/SOCC - Change in behavior as a result of noise and light (including blasting).	As above	Not Significant
Marine SAR/SOCC - Loss of fish habitat due to construction of marine terminal	As above	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
Marine SAR/SOCC - Disturbance and potential change in behavior due to noise from ship traffic, pile driving and blasting	As above	Not Significant
Economy, Land and Resource Use		
Change in land use from occasional recreational/trapping to quarry, with resulting limitations on these activities	Pervasive change in land use patterns within the Study Area that adversely affects a community's use of that land and/or is inconsistent with a designated land use established through a municipal planning process.	Not Significant
Tourism and Recreation		
A decrease in wilderness/nature oriented recreation and tourism within the Project Area and vicinity due to vessel traffic and actual or perceived noise, dust and light	A permanent and widespread change in tourism or recreational activities such that people are no longer able to undertake these activities within the municipality and/or that result in a significant loss of tourism related revenue to local businesses.	Not Significant
Commercial Fisheries		
Temporary loss of lobster fishing grounds due to the marine terminal construction and operation and, as a result, displacement of fishermen into other areas	<ol style="list-style-type: none"> 1. An uncompensated loss of habitat of those fish species that are used for, or support commercial, recreational and/or Aboriginal fisheries; or 2. A sustained decrease in earnings from a fishery due to lower catch quantity and/or quality, or increased fishing costs (i.e., due to longer travel times, loss of gear, additional license fees, etc). 	Not Significant following Offset
Archaeological and Heritage Resources		
None anticipated	An uncontrolled disturbance to, or destruction of, any historical resource considered by the First Nations, provincial regulators or local residents to be of major importance.	Not Significant
Aboriginal Land and Resource Use		
Loss of future opportunities to harvest traditional terrestrial resources on portions of the property (there is currently no harvesting on the site)	Loss of fishing employment/income that could not be replaced within a reasonable time, loss of food resources not present in reasonable proximity to communities, or permanent loss of cultural relationship with the lands, flora and fauna.	Not Significant
Harm to or dispersion of local	As above	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
wildlife; Potential depreciation of the quality of local food and medicinal plants; Potential degradation of the local marine and shoreline habitats		

8.1 Conclusions of the Proponent

As progressively described within this EIS, a series of Project-environment interactions can be expected during the construction, operation and decommissioning of the Black Point Quarry Project. These interactions and their resulting effects on the environment are entirely consistent with and typical of environmental impacts of natural resource development projects in Nova Scotia and elsewhere in Canada. For many reasons the Project site is well suited for a quarry operation. The large, chemically stable granite resource is not used as a potable water supply, the nearest residential property are not situated at the property boundary but rather hundreds or thousands of meters away, the quarry face is directed across open water rather than toward residential development, the resource is located near a deep water, ice free shipping route to a major commercial market, prime fishing areas can be avoided or in the case of lobster habitat occupied by the marine terminal, can be recreated in the immediate vicinity, etc.

Given these considerations and a number of others, the Proponent concludes that the Project is not likely to result in any significant adverse residual environmental effects. In contrast, the Black Point Quarry Project is expected to result in long term direct and indirect employment opportunities, in addition to other positive economic benefits for the local, regional and provincial economies.

1.0 PROJECT INTRODUCTION

1.1 Report Organization

This Environmental Impact Statement (EIS) is organized to reflect the process by which the environmental assessment was conducted. The EIS begins with an introduction to the Project and Proponent. This is followed by a description of the regulatory framework within which the Project will be assessed, a detailed description of the construction, operation, and decommissioning of the Project, a description of alternatives that were considered during Project planning, and a description of the environmental effects methodology that was used.

These sections are followed by a description of the biophysical environment in which the Project will be constructed and operated. Information from these sections is then used to assess the effects of the Project on the biophysical and human environments and identify measures that will be taken to limit or eliminate those effects. Monitoring programs that will help determine the accuracy of the predicted residual impacts are also presented.

A separate section describes the public, First Nation and stakeholder engagement programs that have been, and will continue to be, undertaken. The report closes with a summary describing the effects of the Project on the environment, the effects of the environment on the Project and the cumulative effects from other anticipated developments in the region. In more detail:

Section 1.0 Project Introduction introduces the Project and Proponent and provides background information on the Project. Project location, scope and schedule are presented. Project activities are described in a general way.

Section 2.0 Regulatory Framework describes the primary federal and provincial laws and regulations that mandate and guide the environmental assessment process, as well as the principal laws, regulations and policies that the Project is subject to.

Section 3.0 Project Description provides a comprehensive description of the Project during all phases of development. It lists the project components and structures, outlines the layout of the various facilities and infrastructure, describes site operations and lists emissions and discharges during construction, operation and decommissioning.

Section 4.0 Alternatives to the Project describes alternative means of carrying out the Project that were considered during Project planning, and why the current version of the Project is preferred.

Section 5.0 Environmental Effects Assessment Methodology describes the assessment methodology employed for the EIS. The methodology outlines how each "Valued Component" or VC was chosen, lists probable project-environment interactions, and describes the size of the different study areas selected for the EIS.

Section 6.0 Existing Environment describes the physical, terrestrial, marine and socio-economic characteristics of the study areas. A total of thirteen subject categories are described, ranging from surface and groundwater resources, through marine and terrestrial habitat to First

Nation interests, shipping, and commercial fisheries. This section provides the background or context to Project development.

Section 7.0 Environmental Effects Assessment provides the results of the environmental effects assessment for each VC selected in Section 5.0. Mitigation measures that will be applied to limit or eliminate project effects on the human and ecological environments are also described, and any residual effects or impacts are listed.

Section 8.0 Effects of the Environment on the Project describes the possible effects of severe weather, climate change, and other events on the Project.

Section 9.0 Cumulative Effects considers other anticipated projects in the region and describes how effects from each of these other projects may combine to cause more intense or more regional effects than the Black Point Project alone.

Section 10.0 Proposed Compliance and Effects Monitoring Programs summarizes information first presented in the Effects Assessment (Section 7.0) into a single location so that all proposed follow-up monitoring programs can be reviewed together. The monitoring programs are intended to verify the nature and scope of the predicted impacts, or the lack of impacts, during Project construction and operation.

Section 11.0 Consultation and Engagement Programs lists and describes the various outreach efforts the Proponent has made to the different stakeholder communities over the course of the environmental assessment.

Section 12.0 Assessment Summary and Conclusion summarizes the findings of the EIS, and includes a discussion of residual Project-related effects on the environment, probable effects of the environment on the Project and cumulative effects.

A series of technical reports and other supporting information are contained in the appendices.

1.2 Project Overview

Vulcan Materials Company (Vulcan), a U.S.-based aggregate producer and Morien Resources Corporation (Morien), a Nova Scotia-based resource development company, have jointly prepared this Environmental Impact Statement (EIS), which outlines the proposed development, operation, and decommissioning and abandonment of a hard rock quarry and marine terminal at Black Point in Guysborough County, Nova Scotia (**Figure 1.0-1**). Black Point Aggregates Inc., a wholly owned subsidiary of Vulcan Materials Company, is the named Proponent of the Project. Following the environmental assessment process, Black Point Aggregates Inc. will develop and operate the quarry and marine terminal.

The anticipated average annual production rate will exceed 1.0 million tonnes (MT) with a peak production rate of 7.5 MT per year, should market conditions warrant this production rate. The Project is anticipated to have capital costs on the order of US\$80-\$110 million and will be a significant employer in Guysborough County throughout the expected 50+ year lifespan of the quarry. The total property is 354.5 ha; the finished quarry will occupy approximately 180 ha while the processing plant, administration and stockpile areas together will occupy approximately 28 ha.

This EIS has been prepared to obtain approval pursuant to the federal *Canadian Environmental Assessment Act, 2012* and, at the same time, approval for a Class I undertaking pursuant to the provincial *Environmental Assessment Regulations* made under the Nova Scotia *Environment Act*.

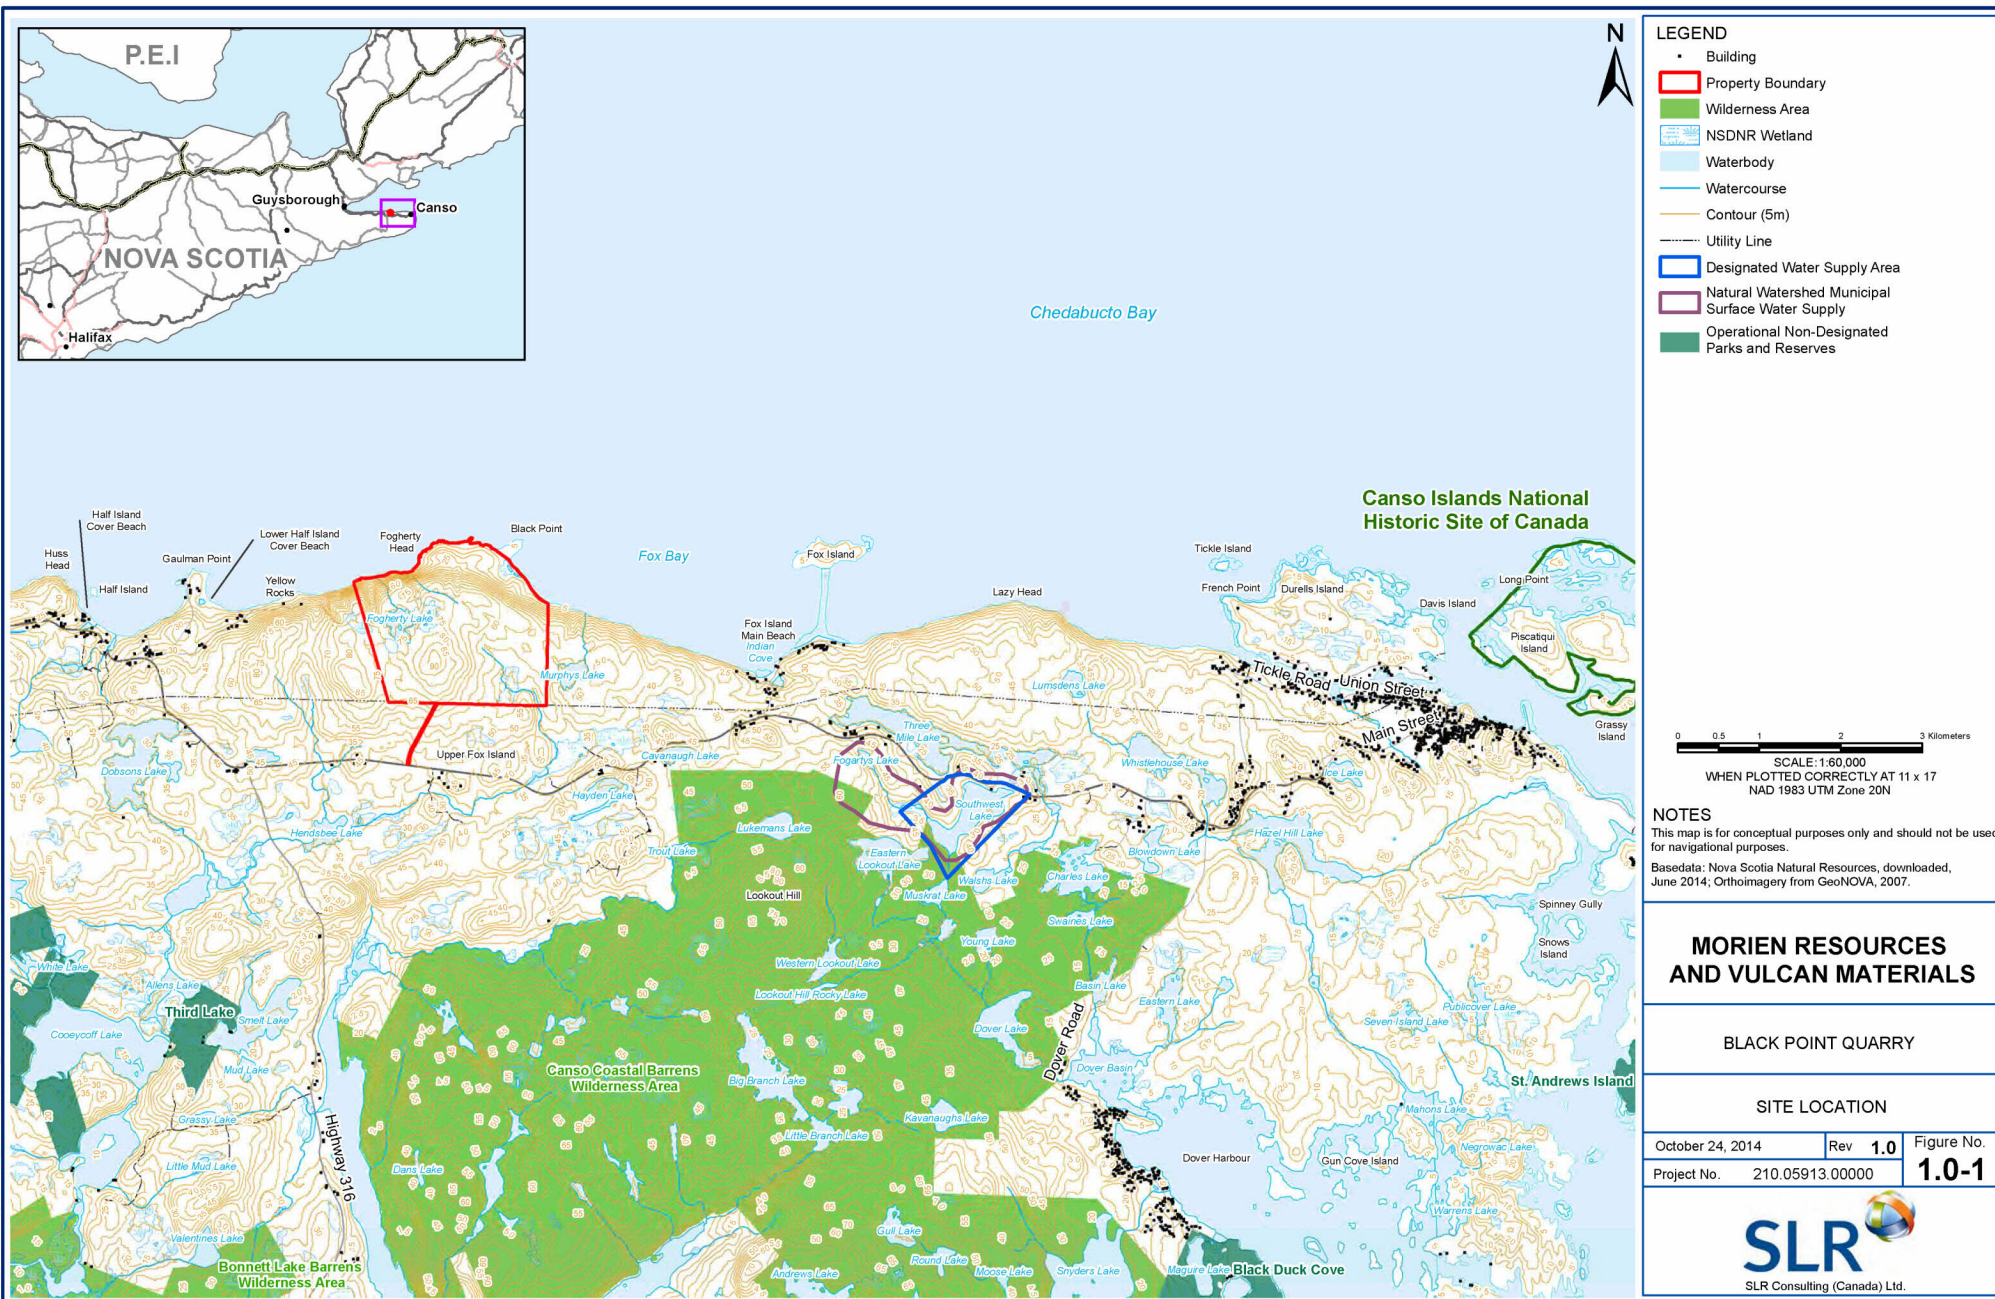

The site for the proposed Project was selected primarily due to the quantity and superior quality of granite rock, combined with thin to non-existent overburden. Rock reserves in the proposed quarry are estimated at more than 400 MT. Also, the proposed quarry is adjacent to deep water, which is sheltered and ice-free. This enables the construction and safe operation of a deep water marine terminal for aggregate shipment. Aggregate from the quarry will be transported in bulk carrier ships, as large as Panamax-sized (up to 70,000 deadweight tonnage or DWT), to ports along the eastern and Gulf coast markets of the U.S.

Electrical power for buildings and equipment (pumps, conveyors, crushers, screens, and ship loading) will be supplied through a tie-in to the existing Nova Scotia Power Inc. (NSPI) electrical transmission line that forms the southern Property boundary. A single pole, 2.5 km long high voltage transmission line (20 m wide right of way) will bring power to the site. A transformer substation will be required to reduce the voltage for the quarry.

Other utilities will include domestic water supply and sewage management or disposal system to facilitate the needs of on-site workers. Entrance to the quarry will be via an access road to be constructed from provincial Route 16 (Marine Drive).

At this time, no public funding is being sought to undertake this Project.

N:\Marketing\Project Files\ 2014\2010.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDoc\3 WRK\210_05913_Site location.mxd

1.3 Project Location

The lands to be developed are owned by the Municipality of the District of Guysborough (MODG) and will be leased to the Proponent. The property is currently undeveloped and is zoned Industrial Heavy I-2 (pers. comm. D. Torrey, 2014). Permitted uses for this zoning includes, among other activities, “rock quarry operation or open-pit mines from which rocks or minerals are extracted” (MODG 2013). The approximate center of the Project site is located at:

45°21'13.25"N

61°08'56.15"W

The municipal land designated for the Project consists of properties assembled through a land exchange with the Province and through expropriation of private lands. The property reference numbers are provided in Table 1.1.

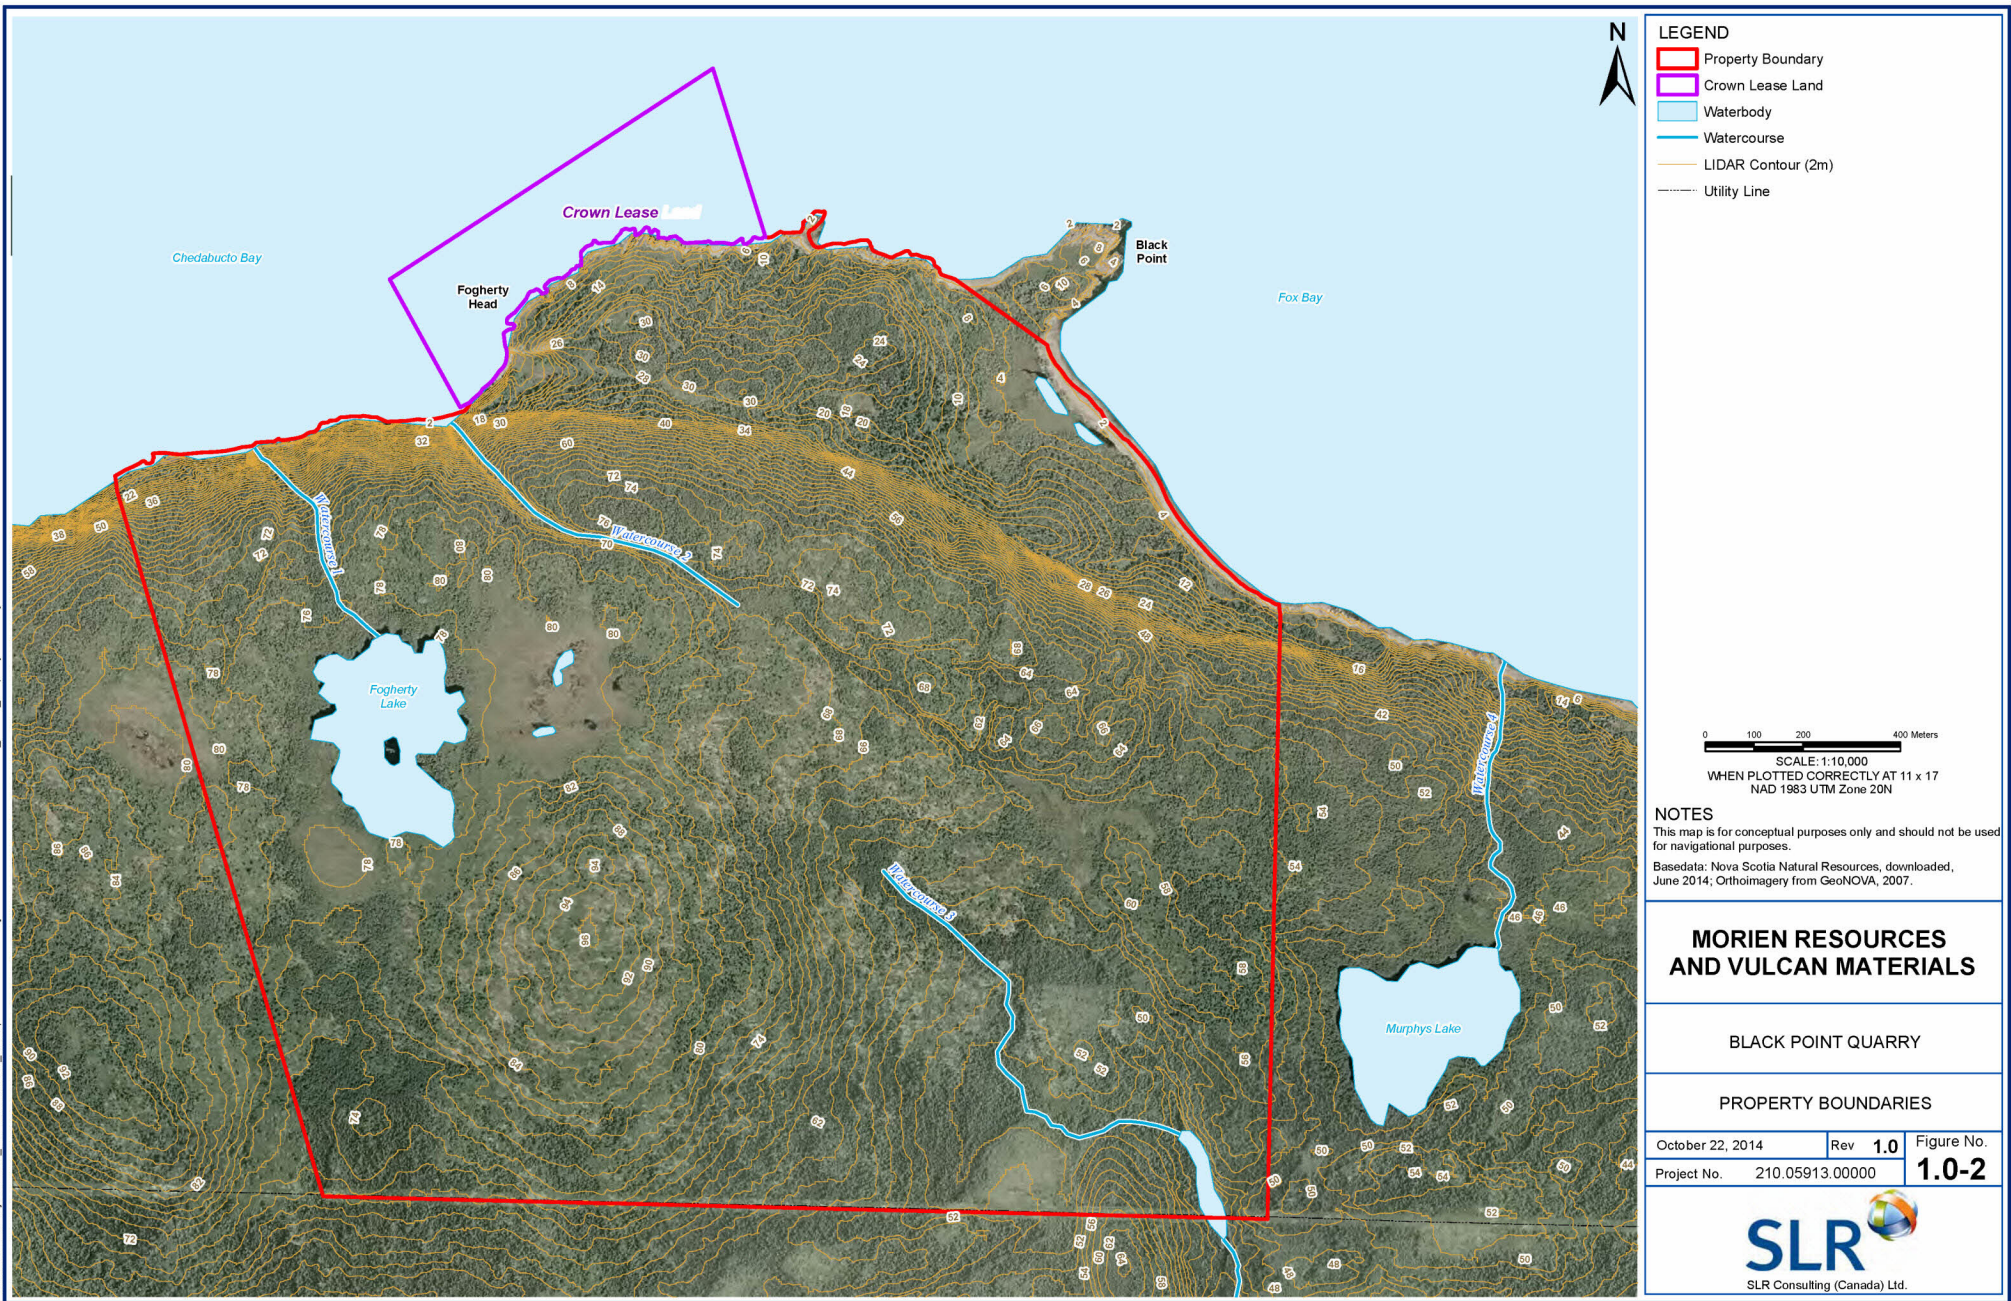

Table 1.1:
Black Point Quarry Property Identification Numbers

Assembled Through Land Exchange w/ Province	Assembled Through Expropriation
1: 35212521	7: 35044056
2: 35212497	8: 35214014
3: 35212505	9: 35214022
4: 35213990	10: 35093210
5: 35212513	
6: 35212539	

The generalized property boundaries are shown on **Figures 1.0-1** and **1.0-2**. Table 1.2 provides coordinates for the four corners of the proposed Project area and the submerged Crown Land Lease that will host the marine terminal. The submerged Crown Land Lease has not yet been granted. The land parcel that includes Black Point itself is Crown land; this parcel is not included in the Project.

The provincial Crown Land in the marine environment needed for the marine terminal has not been previously used as a marine terminal and has not been so designated by the MODG. The Proponent has worked with the MODG and has made application to the Nova Scotia Department of Natural Resources (NSDNR) to lease a portion of the seabed extending from the ordinary high water mark north approximately 300 m to allow for construction and operation of the terminal, shown on **Figure 1.0-3**.

1.4 Geographical Setting

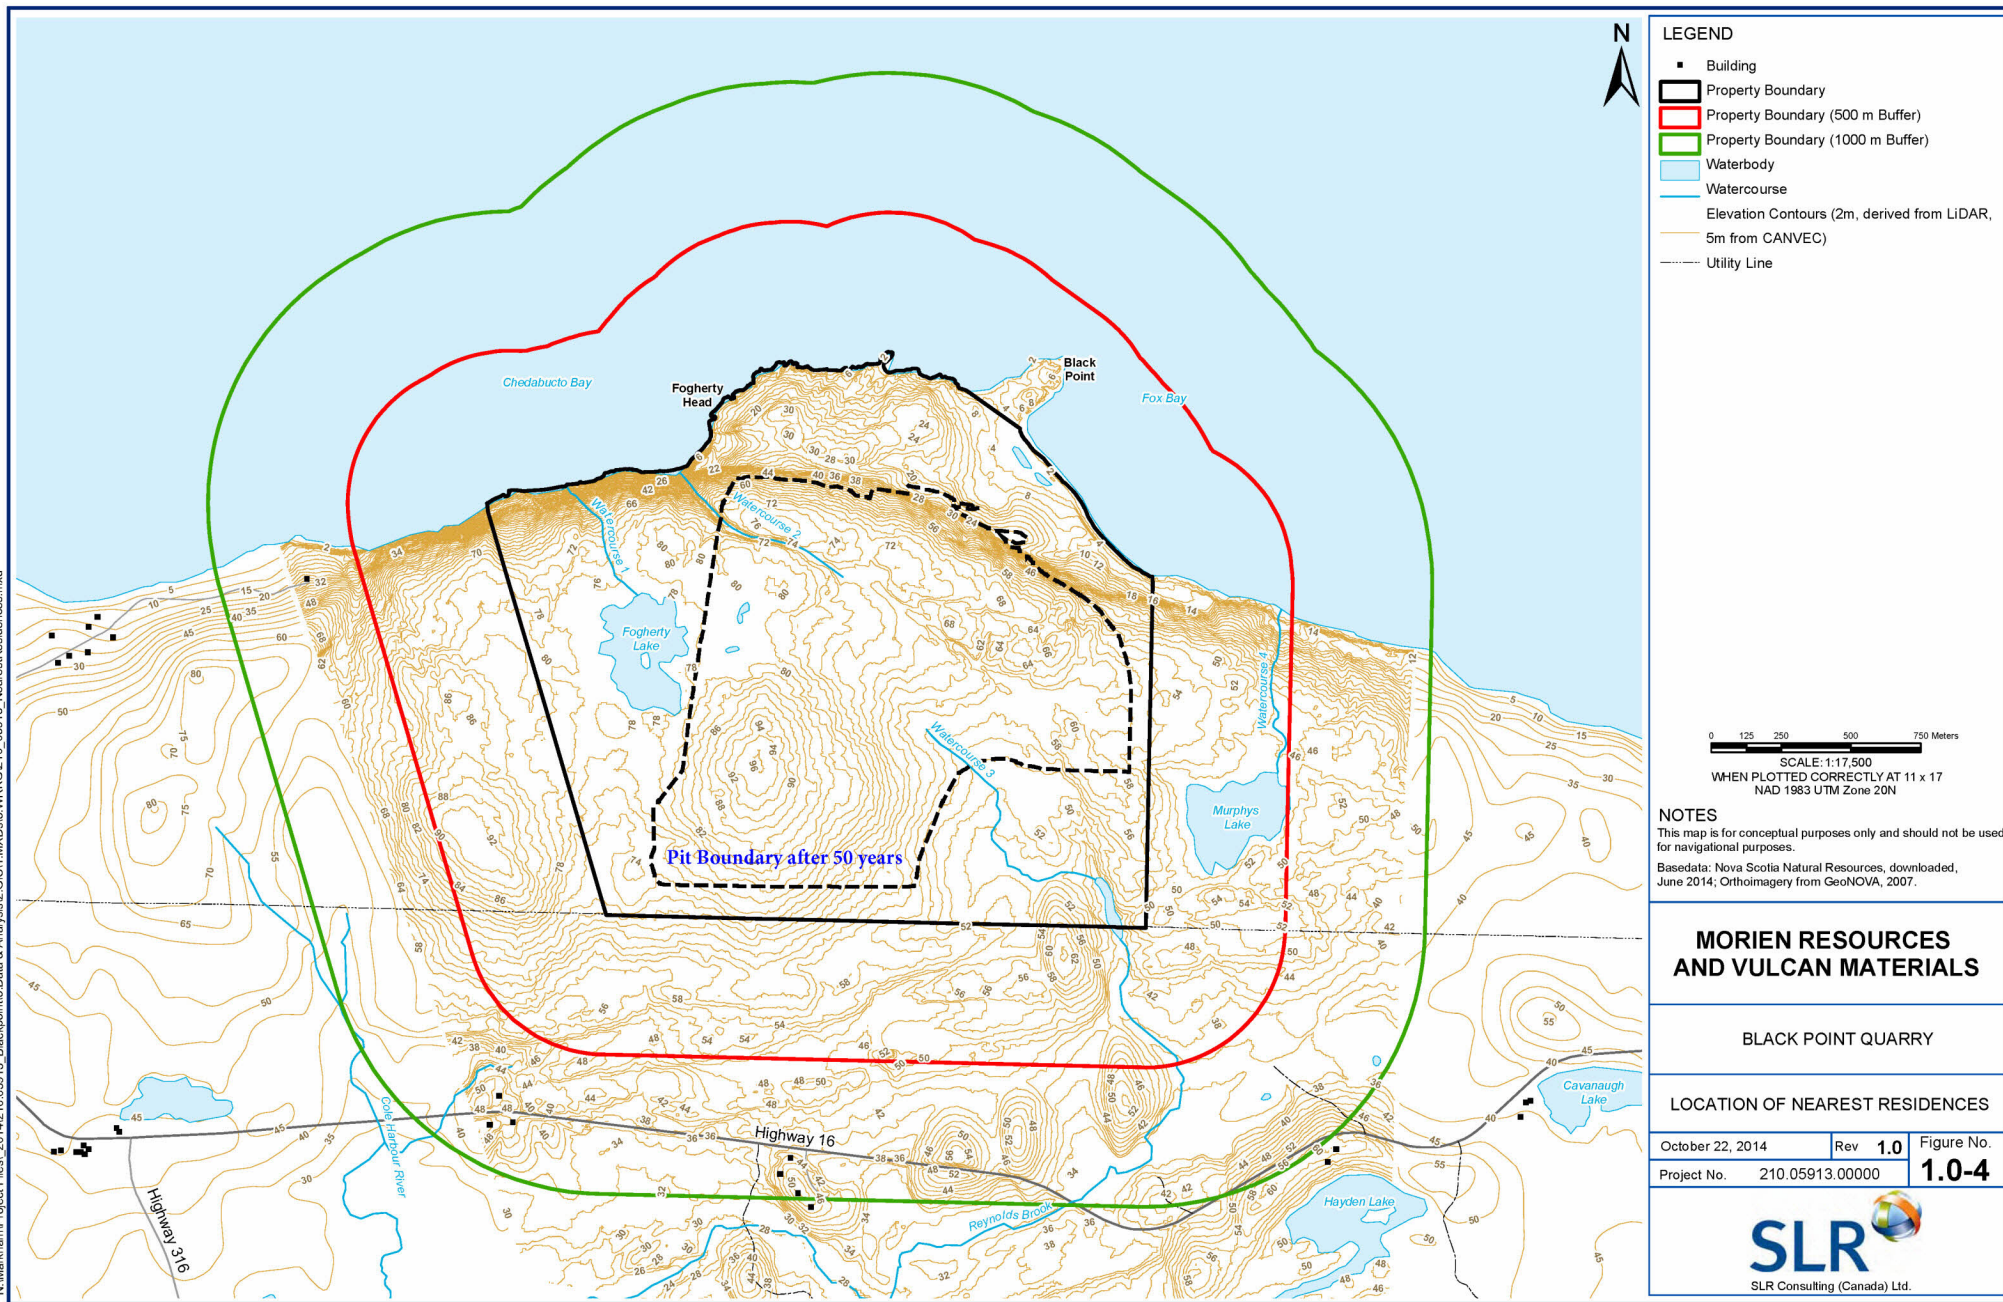

The quarry is proposed for a 354.5 ha property located on the south shore of Chedabucto Bay approximately 4.0 km east of Fox Island in Guysborough County, Nova Scotia. The Project is bound to the north by Chedabucto Bay and to the south by a 69 kV power transmission line. No terrestrial federal lands will be used to undertake this project. The nearest federal lands are the Canso Islands National Historic Site of Canada (which includes the Grassy Island Forts site) located approximately 10 km due east of Black Point (**Figure 1.0-1**).

Although the marine terminal will be constructed within the limits of a provincial seabed Crown Land Lease, aggregate shipping will occur on “federal lands” as defined in CEAA 2012 (S.2b). Federal land in this context refers that portion of the ocean claimed by Canada.

The Project site is located on an undulating granite hill with minimal soil cover and overburden. The hill, which has a maximum elevation of approximately 96 m above sea level (asl), is sloped to the north where a cliff is present. The site levels off abruptly at approximately 22 m asl where it gradually grades to the rocky coast. The regional geology consists of Ordovician age metamorphosed sediments of the Halifax and Goldenville formations, intruded by Devonian age granites (Erdene 2011). The granite is the rock that will be quarried and crushed to produce aggregate.

All blasting will occur more than 900 m away from any residential structures. There are no hospitals, retirement hospices, schools or day care centres located within 5 km of the site. Provincial Route 16 (Marine Drive) runs parallel to the southern boundary of the Project site and is located approximately 750 m south of the site. Residential development in the vicinity of the Project is relatively rare, with no residential structures within 500 m of the property line and fewer than seven within 1.0 km of the property boundary (**Figure 1.0-4**). The nearest residence (an abandoned trailer home, for sale as of September 2014) is approximately 700 m west of the property boundary along Half Island Cove Road. A cluster of three residences is located along Route 16 approximately 750 m southwest of the property boundary. In fact, the quarry will not occupy the entire property; quarrying will stop 95 m inside the eastern property boundary, 125 m inside the southern property boundary and 225 m inside the western property boundary (**Figure 1.0-4**).

N:\Markham\Project Files\ 2014\2010.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\3 WRKG210_05913_NearestResidences.mxd

1.5 Ecological Overview

The 354.5 ha property measures approximately 2.75 km from east to west and is generally less than 2.0 km wide from north to south. Much of the terrain at higher elevations consists of exposed bedrock interspersed with thin, patchy vegetation and stunted trees. Vegetation and tree cover thicken at lower elevations on the flanks of the exposed granite dome. The massive granite rock limits infiltration of rainwater and snowmelt, resulting in a number of wetlands distributed across the property at lower elevations. In these areas (e.g., around Fogherty Lake) and extending north to the coast, wetlands mixed with mature black and red spruce forest dominate the landscape.

There are three unnamed watercourses on the site, including the outflow from Fogherty Lake, the only lake on the Black Point property (**Figure 1.0-4**). The watercourses are narrow, shallow and do not contain fish. One stream is ephemeral. Fogherty Lake is approximately 6.8 ha in surface area, but is relatively shallow and is strongly acidic. Water in the lake is dark brown and visibility is limited. Nearby Murphys Lake (6.0 ha in area) located east of the Black Point Property is also acidic and is ringed by wetlands.

A number of habitat types are encountered within the Project site. Most of the area is covered by a mosaic of barren vegetation, tall shrub barren, and some coniferous forest. There are also patches of mixed forest, and wetlands such as treed bog, open bog, fen, and swamp scattered throughout the Project site. A variety of other habitat types are also present, including beaches, coastal barren headlands, coastal cliffs, regenerating forests, and lakes.

NSDNR's Restricted and Limited Land Use map shows the following features in proximity to the proposed Project (**Figure 1.0-1**).

- Three private beaches protected under the Beaches Protection Act
 - Lower Half Island Cove 1.5 km west
 - Half Island Cove 2.7 km west
 - Fox Island Main 2.55 km east
- Two Wilderness Areas
 - the Bonnet Lake Barrens Wilderness Area (6.9 km southwest)
 - the Canso Coastal Barrens Wilderness Area (1.7 km south and east);
- A Designated Water Supply Area
 - Walsh or Wilkins Lake 4.5 km south and east;
- A Natural Watershed Municipal Surface Water Supply
 - Located 3.65 km south and east; and,
- Third Lake Operational Non-Designated Parks and Reserve
 - Located 4.2 km south and west.

1.6 Participants in the Environmental Assessment

1.6.1 Proponent

**Table 1.3:

1.6.2 Corporate Information

As noted, the Proponent Black Point Aggregates Inc. is a wholly owned subsidiary of Vulcan Materials Company (Vulcan). Vulcan is a publically traded company with stock listing on the New York Stock Exchange under the symbol VMC. The corporate office for Vulcan is located in Birmingham, Alabama. Company governance is overseen by the Company's Board of Directors, which is majority controlled by non-Vulcan affiliated directors.

The President and Chief Executive Officer is Mr. J. Thomas Hill, who also serves on the Board of Directors. The company has a talented and experienced management team that oversees the company's 340+ facilities located in 20 states, Mexico and the Bahamas. Vulcan employs a local management model that organizes the operations into geography- and market-based regions. Each region has a management team responsible for providing direction and management oversight to the operations.

Vulcan has extensive corporate policies and procedures that apply to the company's operations and employees. These policies and procedures ensure consistency across the company with respect to the expectations, responsibilities and operation of various functional areas (e.g., accounting and finance, legal, human resources, etc.). The Safety, Health and Environmental Policy (SHE Policy) specifically addresses the company's commitment and direction regarding SHE issues. The SHE Policy is described in Section 1.6.3.

The Black Point Project will be subject to the same liability protection measures that are provided for other Vulcan operations. The primary liability protection measures are described below:

- Liability protection begins with minimizing the risk of an incident that could create liability. Risk is minimized by incorporating best management and proactive oversight procedures in the design, construction and operation of a project; such measures include:
 - Incorporation of safety protection measures in facility design such as equipment guarding, safe means of access to equipment, benching in quarry pit, etc; and implementation of Vulcan's safety management system to ensure that safe work procedures are followed to minimize the risk of employee injury during equipment maintenance and other work activities;
 - Implementation of Vulcan's Occupational Health and Safety Program that ensures that the employees are protected from work place exposures that could impact their health. The two areas of primary focus in a quarry setting are the control of worker exposure to noise and dust. The employee noise exposure limit applicable to the Black Point operation is 85 dB(A) for an 8-hour work shift. The work place employee exposure limit for crystalline silica exposures is 25 ug/m³ for an 8 hours work shift.
 - Implementation of environmental control measures including dust control systems, containment systems for fuel storage tanks, water treatment systems, site drainage control and implementation of storm water management controls, and other measures that reduce the risk of environmental incidents that could create liability.
 - Training and supervision to ensure employees know how to do their jobs safely, and that they have the knowledge and experience to recognize and react to risks before an incident occurs. Vulcan will provide extensive training to all Black Point employees.
 - Work place and equipment inspections to identify conditions that could result in an incident so these conditions can be modified before an incident occurs. The Black Point Project site will be routinely inspected by plant employees and supervisors to ensure that issues are identified and addressed.
- The Black Point operation will maintain an Emergency Response and Spill Contingency Plan that the employees will be trained to implement in the event of an incident. The plan will outline the steps to be taken, responsibilities of key personnel, notification procedures for alerting emergency response agencies and regulatory agencies, and other measures to be implemented in the case of an emergency or major incident. The Black Point operation will coordinate with local response agencies on response procedures. Supplementary to this Plan, any additional response documents and plans specified by Canadian or Provincial regulations will be prepared and maintained as required.
- The Corporate Risk Management department at Vulcan's head office in Birmingham, Alabama is responsible for management of liabilities associated with the various business units, including any liabilities that arise due to the Black Point operation. Vulcan is self-insured for losses related to workers' compensation up to \$2,000,000 (US) per occurrence and automotive and general/product liability up to \$3,000,000 (US) per occurrence. Vulcan has excess coverage on a per occurrence basis beyond these retention levels. Additionally,

Vulcan maintains insurance coverage for excess liabilities that could arise and that are beyond the level that Vulcan desires to cover through the self-insurance process.

1.6.3 Safety Health and Environmental Policy

As approved by the Board, Vulcan's SHE policy applies companywide, including all subsidiaries. It affirms that Vulcan will be a responsible steward with respect to the safety, health and environmental impact of the company's operations and products. Accordingly, Vulcan will:

- Strive to produce products safely and make concern for public health and the protection of the environment integral parts of Vulcan's operations.
- Endeavor to provide employees with a safe and healthy working environment.
- Reduce waste, conserve energy and recycle materials, to the extent practicable, and dispose of, or treat, waste responsibly.
- Provide education, training and leadership to employees to enable and motivate them to understand and comply with applicable law and these policies.
- Conduct reviews of safety, health and environmental practice at Vulcan facilities to verify compliance with applicable laws and regulations and to identify and correct operational practices that might impair safety, health or environmental quality at such facilities or in the neighborhoods in which we operate.
- Promote responsible stewardship of the company's products with carriers, distributors and customers.
- Promote the adoption of, and adherence to, sound safety, health and environmental practices by on-site contractors and tenants, directing where appropriate that contractors and tenants take corrective actions.
- Advocate the development of reasonable, scientifically sound and cost-effective safety, health and environmental laws and regulations that are based on realistic assessments of risk.
- Support and encourage the development of sound safety, health and environmental standards and practices in the industries in which Vulcan participates.

Vulcan is recognized as a leader in the Safety, Health and Environmental areas and maintains this leadership with a focus on continuous improvement.

As an operating facility within Vulcan Materials, the Black Point operation will be subject to Vulcan's internal policies and procedures as well as all applicable provincial and national regulations and requirements. Vulcan will ensure that the operation maintains compliance with internal and external requirements and expectations by providing training and direction to the site management team and employees, communicating expectations, and then checking through audits and inspections that all requirements and obligations are met. Vulcan understands the importance of providing a safe workplace, protecting our employees from work

place health hazards, being responsible members of the community and good neighbors, and of protecting the environment.

The company has an internal audit department that performs independent audits of the company operations, business units, and personnel for compliance with company policy and procedure. In addition, in the Safety, Health and Environmental (SHE) Audit Policy mandates periodic audits of each operation and of the operating regions.

1.6.4 Environmental Consultants

**Table 1.4:
Environmental Consultant Contact Information**

Name	SLR Consulting (Canada) Ltd.
Postal Address	115 Joseph Zatzman Drive Dartmouth, NS B3B 1N3
Contact Name	Russell Dmytriw, M.Sc., P.Geo
Telephone	902-499-1190
Fax	902-420-9703

Scott Burley	M.Sc. Biologist	AMEC	Wetlands/Terrestrial Habitats
Chris Milley	Senior Environmental Consultant	AMEC	First Nations

1.6.5 Aboriginal Groups

A review of outstanding specific land claims was undertaken during the preparation of the Mi'kmaq Ecological Knowledge Study for the Black Point Quarry Project (Mi'kma'ki All Points Services 2013). At the time there were no specific land claims pending within the Project area. This does preclude future land claims in the area.

The nearest mainland First Nation (Mi'kmaq) community is Paqtnkek First Nation located in Afton, NS. Paqtnkek First Nation is 66 km north of Queensport in Antigonish County, mid-way between the Canso Causeway and the Town of Antigonish.

In addition to Paqtnkek, some members from the Millbrook and Sipekne'katik First Nations have been involved in the resource harvesting in the lands and waters near the Project area, and as a result are familiar with the region. Two other Mi'kmaq communities, Pictou Landing and Potohtek, are also in relatively close proximity to the Project Site (i.e., <150 km away).

The Assembly of Nova Scotia Mi'kmaq Chiefs is a key Aboriginal group, which has also participated in the environmental assessment process.

1.6.6 *Community and Environmental Organisations*

A number of community and environmental groups have expressed an interest in the Project, either through direct contact with the Proponent or through submissions made to the CEA Agency and NSE during the course of the environmental assessment. The Proponent's outreach efforts to these and other groups are described in Section 11. Table 1.6 lists the community and environmental organisations associated with the Project.

**Table 1.6:
Environmental and Community Organisations**

Organization	
1	Chedabucto Education Centre/Guysborough Academy
2	Guysborough Memorial Hospital Foundation
3	Chedabucto Lifestyle Center
4	Guysborough County Adult Learning Association
5	Guysborough County Food Bank
6	Canso Lions Club

1.7 Project Schedule

Table 1.7 provides a generalized schedule that presents the major construction and operational milestones.

**Table 1.7:
Generalized Project Schedule**

Year	Activity Undertaken or Anticipated
2010-11	Baseline ecological studies initiated
	Initial engagement with the public, regulatory agencies and Mi'kmaq
2012-2013	Properties assembled by the MODG (beginning in 2007-2008)
	Environmental Assessment Initiated
2014	<ul style="list-style-type: none"> • Consultation and engagement undertaken: • Meetings and site visits with Mi'kmaq representatives • Consultation and site visits with Regulatory Agencies • Meetings with residents and local fishermen • Open Houses, presentations, and meetings of the Citizen's Liaison Committee (CLC) • Submission of the draft EIS for review by the CEA Agency and NSE
2015	Submission of the Environmental Impact Statement report
	Completion of the environmental assessment
2016	Permits and Approvals
Early 2017	Updated Market Evaluation
2017-2018	Establishment of Sales Yards Receipt of Aggregate by Vessel from Black Point
2018-2021	Construction and Equipment Testing (Limited Production)
2021	Commence Full Scale Operations
2070+	Closure and Decommissioning

1.8 Purpose of the Project

The purpose of the Black Point Quarry Project is to supply construction aggregate to markets predominantly on the eastern and Gulf coasts of the United States and possibly to markets in eastern and central Canada. Construction aggregates are composed primarily of crushed stone (the product from Black Point), natural sand and gravel. These resources are needed for the development and maintenance of modern infrastructure. Although construction aggregates have numerous end uses, their general application is in the production of building materials such as concrete and asphalt. In general concrete is about 80% aggregate and asphalt is about 94% aggregate.

While natural materials used to produce construction aggregates (stone, sand and gravel primarily) are relatively abundant, these resources must be located in areas that are geographically accessible. In addition, the rights and permits to recover the resources must be obtainable, and there must be sufficient market capacity to support the planned production of the mining operation. Finally, aggregates must meet strict quality requirements related to the chemical and physical characteristics of the rock. Most rocks do not meet these geographic conditions and quality specifications and cannot qualify as viable construction aggregate resources.

In the U.S. market, the majority (80% or more) of aggregates are transported by truck from the quarry to the consumer. This form of transport is expensive and limits the typical aggregate operation to a market radius of about 80 km from the quarry. Coastal markets within the US are increasingly using high volume modes of transportation such as rail and ship to minimize costs. The south eastern U.S. aggregate market is a prime target for bulk vessel transported aggregate due in part to the geologic absence of suitable aggregate resources in coastal areas. For example, the Martin Marietta Materials quarry at Aulds Cove, NS shipped nearly 300 vessels of crushed stone to Florida ports between 2004 and 2009 (ACS 2009).

1.9 Benefits of the Project

The benefits of the Black Point Quarry Project to Canadians and Nova Scotians are numerous. The revenue generated from the Project will provide economic benefit to the people and governments of Guysborough County and Nova Scotia through taxes paid, dollars invested into goods and services directly by the Project Proponent, and indirect dollars that will go into local businesses and services from employees and contractors working on the Project and at the quarry. Specifically, the investment will be in the US\$80-\$110MM range. The construction and site development phases of the Project will generate between 120-150 direct and indirect jobs. Once operational, there will be 50-60 full time jobs associated with the operations. Based on experience at other Vulcan quarries, the annual operating expenses are estimated to be in the range of US\$9-\$15MM which is spent on wages, fuel, electricity, operating parts and maintenance. Additionally, numerous local vendors, service providers and consultants would be engaged in activities at the quarry.

Additional benefits that the environmental assessment process has generated since the Project was proposed revolve around the increased levels of consultation the community, the Mi'kmaw, and local fishermen. The dialogue that has occurred to date has been driven by a genuine interest to harmoniously coexist with the Project's Guysborough County neighbours, but is also mandated in the assessment process and facilitated by open comment periods. Exchanges with these groups, numerous site visits, and presentations at schools and business forums have improved the quality of information presented in the EIS report and established a baseline example for future interactions over the life of the Project.

Examples of changes to the Project and critical information incorporated into the EIS through community dialogue include:

Fisheries

- Over the course of multiple consultation events, the Proponent's proposed vessel approach routes between the marine terminal and the main shipping lane in Chedabucto Bay were reviewed and critiqued by local area fishermen. This process resulted in the selection and

modification of a preferred route intended to avoid preferred fishing grounds to the extent possible¹.

- Several potential fisheries offset project locations were identified during meetings with local fishermen. These include areas immediately west of the Project and well as in Indian Cove.
- Mackerel and shrimp migration patterns in the immediate area nearshore environment to the marine terminal are best understood by the fishermen. Mitigation measures will take that input into account.
- Lobster spawning concerns and considerations relative to blasting in the nearshore terrestrial environment were issues that the fisherman wanted more information about and assurances that no impact will occur. The Proponent provided the fisherman with academic studies related to blasting in the nearshore environment and utilized the same information to generate blasting setbacks as reported in this EIS report.

The Mi'kmaw

- The constructive and open dialogue encouraged during meetings, presentations and site visits have generated a mutual awareness and understanding of the needs and intentions of the other, which will survive the duration of the environmental assessment process.
- The Mi'kmaw have been made aware of the anticipated benefits of the Project, the potential environmental impacts and proposed mitigation measures aimed at minimizing those impacts as well as the sustainable practices and environmental track record of the Proponent.
- The Proponent has learned a great deal with respect to Mi'kmaq history, culture, and land use rights in Nova Scotia. The Proponent has also been made aware of type and number of Mi'kmaq labor and vendor resources who desire training and employment, which the Project will need during construction and operation.

Local Community

- Several meetings and presentations were used to describe mining processes and quarry-specific vocations to interested students to help prepare them for Project related employment opportunities.
- Meetings were also used to describe background environmental conditions including residential water quality results, wetland function and the results of biological surveys.

The baseline environmental testing and monitoring at the site add to the scientific understanding and background data held by the Province. This background information contributes to a knowledge base that ultimately helps to increase public ecological awareness and promote conservation.

¹ The local fishermen selected a preferred route (one of two presented) then requested further modifications to the preferred route, which were incorporated to establish a final route shown on Figure 3.0-29.

2.0 REGULATORY FRAMEWORK

2.1 Federal

The Black Point Quarry Project is proposed within a framework of federal and provincial laws and municipal by-laws. These laws describe the environmental assessment process, the permits required for operation and construction, and the conditions under which the Project will be operated. The Project is also subject to a number of guidelines, policies and standards that are applied during the design, construction and operation of the Project. Governing legislation is listed in **Table 2-1** while the key laws are described in more detail below.

2.1.1 *Canadian Environmental Assessment Act (CEAA 2012)*

The *Canadian Environmental Assessment Act, 2012 (CEAA 2012)* regulates the federal government's environmental assessment process. Section 8 of *CEAA 2012* requires that the Proponent of a "designated project" provide the Canadian Environmental Assessment Agency (CEA Agency) with a Project Description so that the federal Minister of the Environment can determine whether an environmental assessment is required. Designated project types are listed in the *Regulations Designating Physical Activities*. The Black Point Quarry Project includes two activities (or project types) listed in the *Regulations* and is therefore subject to a federal environmental assessment:

16(g) the construction, operation, decommissioning and abandonment of a **new stone quarry** or sand or gravel pit with a production capacity of 3,500,000 tonnes per year or more;

24(c) the construction, operation, decommissioning and abandonment of a **new marine terminal** designed to handle ships larger than 25,000 DWT unless the terminal is located on lands that are routinely and have been historically used as a marine terminal or that are designated for such use in a land-use plan that has been the subject of public consultation.

The CEA Agency both leads and coordinates agency review of and response to the Proponent's EIS report.

2.1.2 *Canadian Environmental Protection Act 1999*

The *Canadian Environmental Protection Act 1999 (CEPA 1999)* is aimed at the prevention and management of risks posed by toxic and other harmful substances. CEPA 1999 also manages environmental and human health impacts of marine pollution, disposal at sea, certain atmospheric emissions, hazardous wastes, environmental emergencies and other sources of pollution.

With respect to marine pollution, CEPA 1999 provides the authority to issue non-regulatory objectives, guidelines and codes of practice to prevent marine pollution from land-based sources. It also prohibits the disposal of wastes at sea within Canadian jurisdiction and by Canadian ships in international waters unless a permit is obtained. Dredging is not currently anticipated at the Black Point Project; should this change, a permit allowing disposal at sea of dredged materials would be required.

2.1.3 Fisheries Act

The recently amended *Fisheries Act* protects the sustainability and productivity of recreational, commercial and Aboriginal fisheries. Among other things, the amendments re-emphasize the Proponent's responsibility to avoid harm to fish and fish habitat through the application of appropriate design and mitigation measures.

People are prohibited from harming fish in section 35(1) *No person shall carry on any work, undertaking or activity that results in serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or to fish that support such a fishery, except if the work or activity is authorized by or carried on in accordance with the regulations made under the Act.* This prohibition is supported by definitions of commercial, recreational and Aboriginal fisheries in the *Act*, as well as a definition of "serious harm to fish", which is the *death of fish or any permanent alteration to, or destruction of, fish habitat.*

In addition, Section 36(3) of the *Fisheries Act* prohibits discharge or deposit of "a deleterious substance in water frequented by fish" unless allowed by regulation.

In consequence of this regulation, DFO authorization may be required to construct the marine terminal. In contrast, no freshwater fishery is present due to the low pH of Fogherty Lake and the freshwater streams on the site, and so no DFO authorization is required for the terrestrial components of the Project.

2.1.4 Migratory Birds Convention Act, 1994

The *Migratory Birds Convention Act* (MBCA) protects migratory bird species and states that no person shall disturb, destroy or take a nest, egg, nest shelter, eider duck shelter or duck box of a migratory bird without a permit. Section 5.1 of the Migratory Birds Convention Act prohibits the deposit of substances harmful to migratory birds:

"5.1 (1) No person or vessel shall deposit a substance that is harmful to migratory birds, or permit such a substance to be deposited, in waters or an area frequented by migratory birds or in a place from which the substance may enter such waters or such an area.

(2) No person or vessel shall deposit a substance or permit a substance to be deposited in any place if the substance, in combination with one or more substances, results in a substance — in waters or an area frequented by migratory birds or in a place from which it may enter such waters or such an area — that is harmful to migratory birds."

2.1.5 Species at Risk Act

The *Species at Risk Act* (SARA) protects wildlife species from becoming extinct through prohibitions against killing, harming, harassing, capturing or taking species at risk, and against destroying their critical habitats. Management of species at risk and species of special concern (as identified by the Committee on the Status of Endangered Wildlife in Canada [COSEWIC]) is accomplished by providing for the recovery of species at risk and by ensuring through sound management that species of special concern do not become endangered or threatened. In the aquatic environment, DFO is responsible for freshwater and marine species at risk, while Environment Canada (EC) is responsible for all other species at risk.

2.1.6 Canada Shipping Act, 2001

The *Canada Shipping Act, 2001* governs safety in marine transportation, recreational boating and the protection of the marine environment. It applies to Canadian vessels operating in all waters and to all vessels operating in Canadian waters. The *Vessel Pollution and Dangerous Chemicals Regulations* for lists prohibited ship-source discharges including: oil, noxious liquid substances and dangerous chemicals, sewage, garbage and air anti-fouling systems. Regulations under the Act are also meant to prevent and respond to marine spills from vessels and require vessels to manage ballast water to reduce the potential for invasive (non-native) organisms (*Ballast Water Control and Management Regulations*).

2.1.7 Oceans Act

The *Oceans Act* sets out Canada's role with respect to oceans management, specifying the need to integrate marine conservation with development activities to maintain healthy ecosystems. The *Act* is implemented through three programs: the Marine Protected Areas Program (a national system of marine protected areas, including designating areas for special protection), the Integrated Management Program (leading, facilitating and implementing plans for the integrated management of all activities or measures in or affecting estuaries, coastal and marine waters), and the Marine Ecosystem Health Program (establishing marine environmental quality guidelines).

2.1.8 Navigation Protection Act

The Navigation Protection Act (NPA) protects the public's right to navigation and marine safety in Canadian waters. Administered by Transport Canada, the NPA requires approval for any works that may affect navigation on navigable waters in Canada. Given this, the construction of the marine terminal will require approval under Section 6(1) of the NPA.

In addition to these laws, the follow legislation also applies to the Black Point Quarry Project:

- The *Marine Transportation Security Act* provides regulatory measures for marine and port security.
- The *Pilotage Act* the General Pilotage Regulations and the Atlantic Pilotage Authority Regulations establish pilotage authority and requirements within areas where local ship pilots are required by law to assist the masters (captains) of incoming vessels. The Black Point marine terminal is situated within a Compulsory Pilotage Area administered by the Atlantic Pilotage Authority.

2.2 Provincial

2.2.1 Environmental Assessment

Provincial environmental assessments are regulated under Nova Scotia's *Environment Act* and *Environmental Assessment Regulations*. Projects subject to environmental assessment are divided into two classes, Class I and Class II. As a quarry larger than 4 ha and an undertaking that may disrupt wetlands in excess of 2 ha, the proposed Project is considered to be a Class 1 Undertaking, which requires the submission of an Environmental Assessment Registration Document. Further requirements for the provincial environmental assessment process have

been established in the Guide to Preparing an EA Registration Document for Pit and Quarry Developments in Nova Scotia (NSE 2009a).

Many of the provincial permits required for this Project, including the primary operating permit - the Industrial Approval - originate from stipulations in the provincial *Activities Designation Regulations* made under Section 66 of the *Environment Act*. The *Activities Designation Regulations* provide permitting guidance to watercourse alterations and wetland alterations, groundwater surface water withdrawal, and construction of infrastructure in the marine environment.

The application for Industrial Approval, like other permit applications, is made once environmental assessment approval has been received. The Industrial Approval defines specific operational conditions and limitations, including dust, noise, surface water and groundwater discharge criteria and follow-up monitoring plans.

2.2.2 Harmonization

CEAA 2012 also allows the federal Minister of Environment to enter into agreements with provincial and territorial governments relating to the environmental assessments of projects where both federal and provincial governments have an interest. For this project, the CEA Agency and NSE have determined a harmonized federal/provincial environmental assessment process is achievable. A Federal-Provincial Environmental Assessment Agreement has been established to define the roles and responsibilities of the different departments, establish a timeline for the review process, and ensure the federal and provincial requirements are coordinated. This Agreement stipulates that a single environmental assessment report will address the interests of both federal and provincial government departments and agencies.

2.2.3 Resource Management Initiatives

There are a number of government initiatives and resource management policies that have implications to the Black Point Project design and operation. Most important are those wildlife conservation and management policies applicable to Species at Risk. In addition, a number of commercial fishery resource management initiatives have been implemented by DFO and the Guysborough County Inshore Fisheries Association (GCIFA).

Once a species is listed under the provincial *Endangered Species Act*, a Recovery Plan is developed for those species designated Endangered and Threatened and a Management Plan is developed for Vulnerable designated species.

The Mainland Moose Recovery Plan is once such policy (NSDNR 2007a). Nova Scotia's Mainland Moose population was first listed as provincially endangered in 2003. The Recovery Plan defines the recovery goal, objectives, strategies, and actions that have been developed to protect, conserve, and recover this species in Nova Scotia. The objectives of the Plan are to: 1) maintain and enhance the current population and distribution; 2) mitigate threats that limit recovery; 3) initiate research to address knowledge gaps; and 4) maintain and enhance habitat. The Plan indicates that these objectives will be achieved through research, monitoring, management, education and stewardship. Since Mainland Moose have been identified on the Black Point Quarry property and the Project is expected to impact this species, the Proponent has integrated the objectives and recovery approaches within the design and long term monitoring objectives of the Project (Section 7.12).

Funding for research aimed at understanding conservation options for three recently listed bat species has also been allocated by the province (not related to the Black Point Project), although a specific recovery plan has not been developed for these species. Bat populations have suffered severely from a fungal infection termed white-nose syndrome, which has led to catastrophic population declines in eastern North America.

DFO has developed Integrated Fisheries Management Plans (IFMPs) to manage and guide the sustainable management of commercial fisheries resources (DFO 2014a). Among other things the plans establish fishing seasons and fishing quotas. Within the Maritimes Region (where the Project is situated) IFMPs are in place for:

- Lobster
- Herring
- Atlantic Seal (various species)
- Atlantic Mackerel
- Bluefin Tuna
- Atlantic Swordfish and Other Tunas
- Canadian Atlantic Herring
- Canadian Atlantic Swordfish and Other Tunas
- Shrimp – Scotian Shelf

The use of these IFMPs to guide commercial fisheries in Chedabucto Bay is described in Section 6.10.

The *National Framework for Canada's Network of Marine Protected Areas* seeks to establish a network of marine protected areas (MPAs) in Canadian waters. The overarching objective of the *Framework* is to provide long-term protection of marine biodiversity, ecosystem function and special natural features. To achieve this objective, the *Framework* provides guidance for Canadian MPA network planning and design and states that MPA networks should identify Ecologically or Biologically Significant Areas (EBSAs). To this end, the Canso Ledges EBSA, which includes the Project site, was identified in 2012 (DFO 2012a).

2.2.4 Permits and Authorizations

In addition to the above-described environmental assessment requirements, the Project will also require a number of federal and provincial regulatory permits and approvals prior to proceeding. These permits are typically issued after the successful completion of the environmental assessment. The key environmental permits anticipated are listed in **Table 2.1**.

**Table 2.1:
Anticipated Key Permitting Requirements**

Regulatory Requirement	Approval/Permit	Sections	Project Activity/Trigger	Responsible Agency
FEDERAL				
CEAA 2012	Assessment	S. 16(g), 24(c)	Construction of a stone quarry of greater than 2.5 MT capacity; construction of a marine terminal hosting vessels larger than 25000DWT	CEA Agency
Fisheries Act and Regulations	Authorization	S. 35(1)	Marine terminal construction; prohibits deposit of a deleterious substance in waters frequented by fish	Fisheries and Oceans Canada
Navigation Protection Act	NPA Approval	S. 6 (1)	Marine terminal construction, installation of watercourse crossings	Transport Canada
Transportation of Dangerous Goods Act	NA	NA	The movement of dangerous good to, from and within the site must comply with applicable regulations under the Act	Transport Canada
Migratory Birds Convention Act	NA	S. 5 and 5.1	The Proponent will comply with the Migratory Birds Convention Act and associated regulations, including prohibitions against harming migratory birds to depositing substances which may harm these birds	Environment Canada
Canada Shipping Act (Ballast Water Control and Management Regulations)	NA	NA	Code of practice for shipping operations	Transport Canada
National Building Code of Canada	Approval	NA	Building occupation	MODG
PROVINCIAL				
Environmental Assessment Regulation under the NS Environment Act	Approval/Release	32	Prohibits work on an undertaking without an approval	Nova Scotia Environment
Activities Designation Regulations under the NS Environment Act	Water Approval	S. 5(1) various	Water withdrawal, alteration of water bodies and/or wetlands associated with quarry development	Nova Scotia Environment
Activities Designation Regulations NS Environment Act	Part V Industrial Approval	S. 13(f)	Quarry development and operation	Nova Scotia Environment
Activities Designation Regulations under the NS Environment Act	Permits	various	Wharf construction, chemical storage tank in excess of 2000L, wastewater treatment system	Nova Scotia Environment

Regulatory Requirement	Approval/Permit	Sections	Project Activity/Trigger	Responsible Agency
			construction, etc.	
Petroleum Management Regulation	Registration	S. 11(1)	Underground and aboveground petroleum storage tanks of 2000L or greater	Nova Scotia Environment
Air Quality Regulation	NA	Schedule A	Establishes ambient air quality criteria	Nova Scotia Environment
Dangerous Goods Management Regulation	Approval	S. 6(1)	Requires written approval to store dangerous waste goods	NSDNR
Beaches Act and Beaches Regulations	Permit	S. 7	Authorizes construction activities below the ordinary high water mark	NSDNR
Special Places Protection Act and Regulations	Permit	S. 8(1)	Authorizes an Archaeological Resources Impact Assessment	NS Department of Communities, Culture and Heritage
Nova Scotia Wildlife Act and Regulations	Permit	50(1)	Prohibits the taking, hunting or killing or possession of eagles, osprey, falcons, hawks, owls or any protected wildlife	NSDNR
Nova Scotia Endangered Species Act	Permit	S. 14	Prohibits harm to or interference with an endangered or threatened species and their habitat. The permit authorizes activities that would otherwise be prohibited	NSDNR
Crown Lands Act and Regulations	Crown Land Lease for Submerged Lands		Governs the use of lands owned by the Province. A Lease is required for use of the seabed to construct the marine terminal	NSDNR

As the Project is currently planned, no explosives will be stored or manufactured on site and no dredging will be required.

2.3 Municipal

The Municipality of the District of Guysborough employs a Land Use By-Law to manage development within the municipality. Aggregate quarries are permitted in lands zoned Industrial Heavy (I-2) but these projects must obtain a development permit prior to construction. Applications must be accompanied by site plans showing lot dimensions, structures and buildings, location of watercourses, and other information. Building permits will also be required prior to construction.

2.4 Policies and Guidelines

There are a number of federal and provincial policies, guidelines, standards and codes of practice that will apply to the construction and operation of the Black Point Project. Table 2.2 lists these documents.

**Table 2.2:
Federal and Provincial Policies and Guidelines**

 19. Storm Drainage Works Approval Policy (NSEL 2002).
 20. Pit and Quarry Guidelines (NSEL 1999).
 21. Proponent's Guide: Engagement with the Mi'kmaq of Nova Scotia (Government of Nova Scotia 2009).
 22. Guidelines for the Development on Slates in Nova Scotia (NSE 1991).

2.5 First Nations

As noted in Section 1.6.5 a review of outstanding specific claims was undertaken during the preparation of the Mi'kmaq Ecological Knowledge Study undertaken for this project. At the time there were no specific claims pending within the Project area. This does preclude future land claims in the area. To the best of the Proponent's knowledge, there are no treaty or self-government agreements with the Mi'kmaq that are pertinent to the project and/or the environmental assessment.

3.0 PROJECT DESCRIPTION

3.1 OVERVIEW OF PROJECT COMPONENTS AND SITE LAYOUT

The Black Point Quarry Project consists of aggregate production (drilling, blasting, processing, and stockpiling), along with the construction and operation of a marine terminal in Chedabucto Bay adjacent to the quarry.

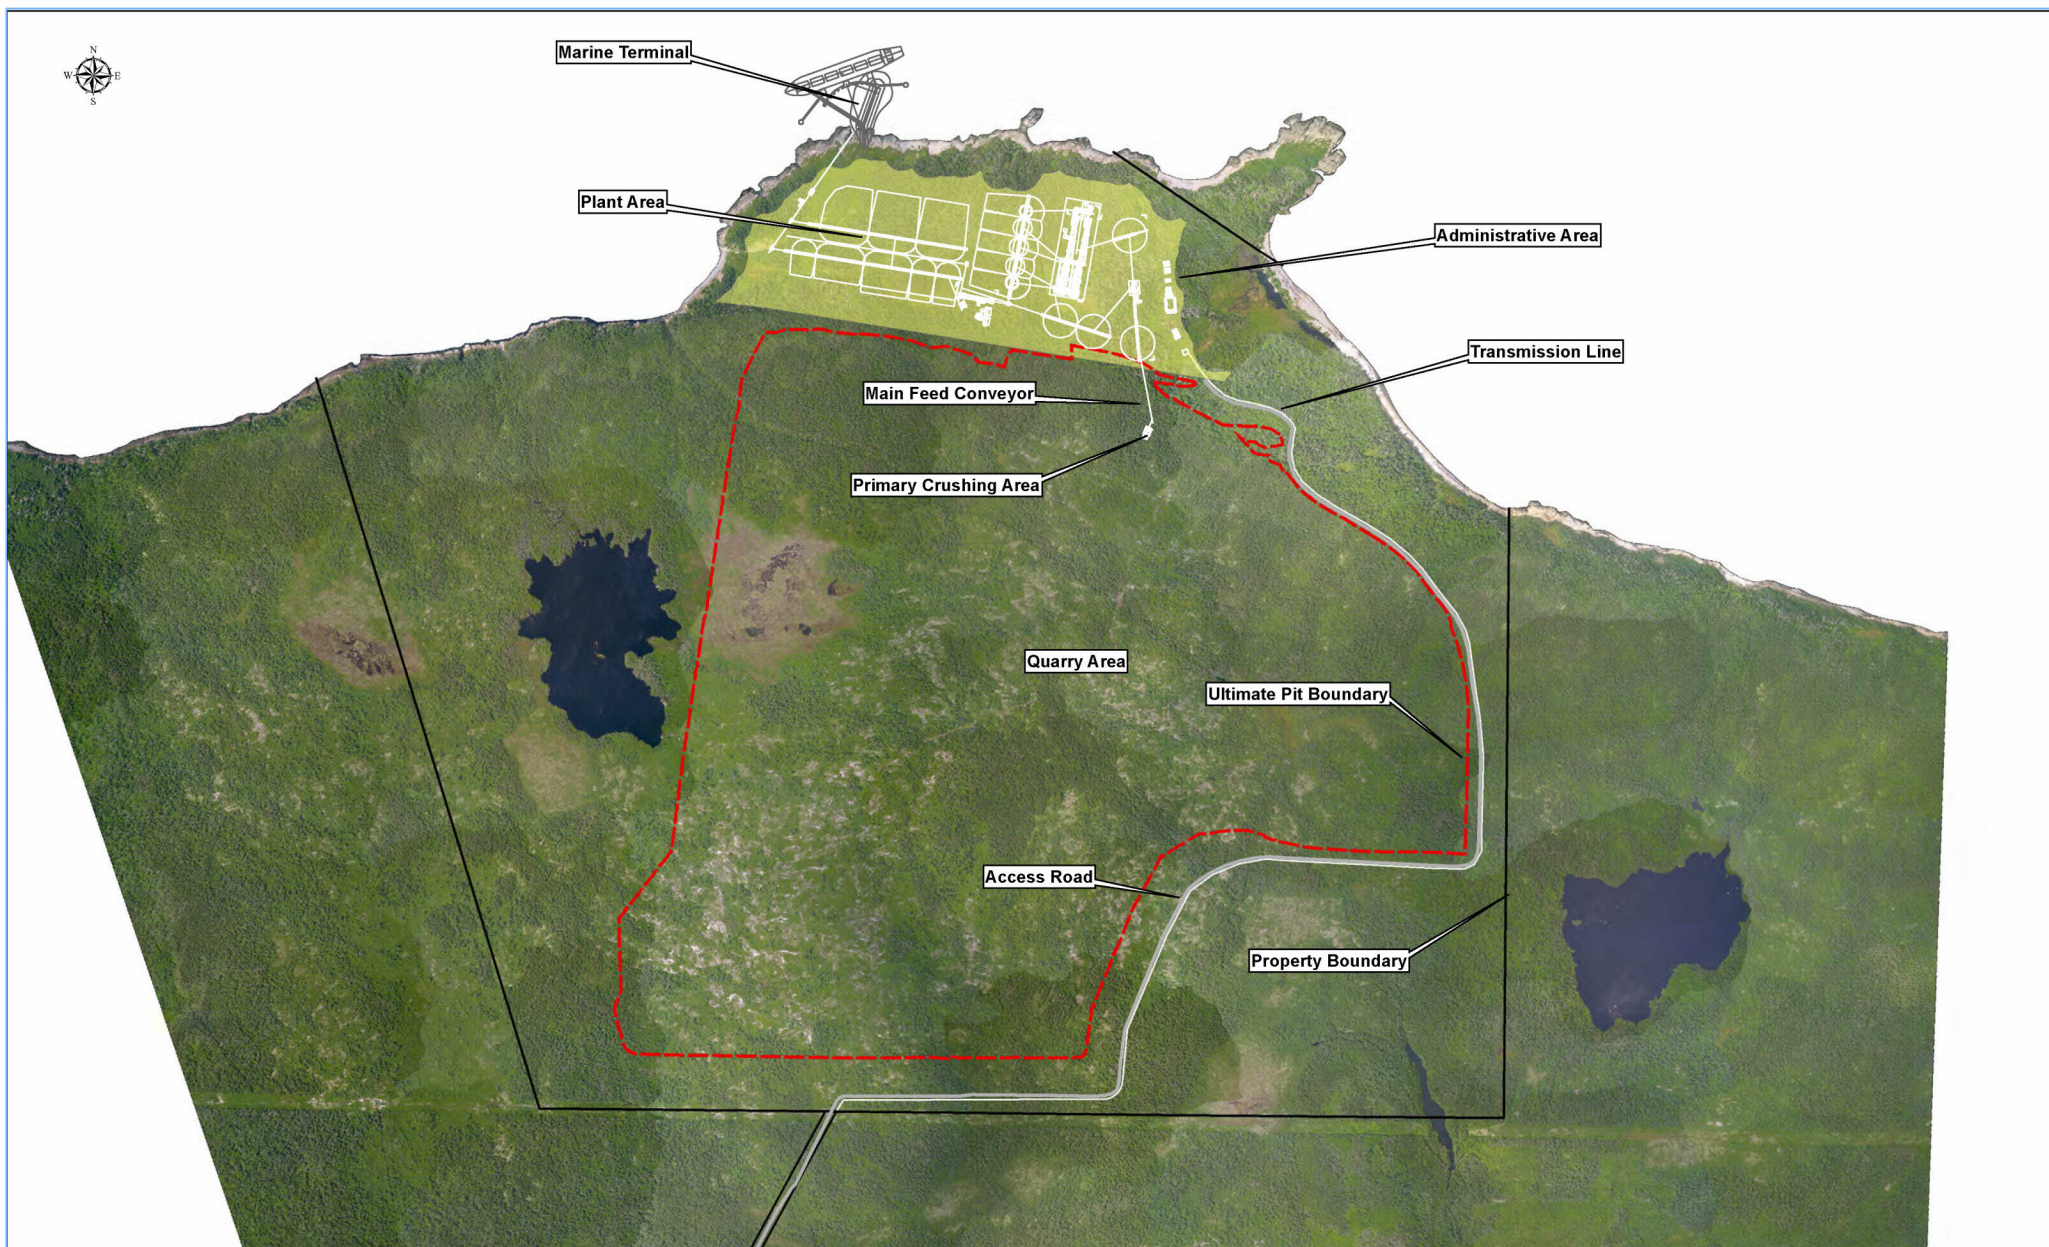

The anticipated average annual production rate will exceed 1.0 million metric tonnes (MT) with an anticipated peak annual production of 7.5 MT depending on prevailing market conditions. Estimated rock reserves in the proposed quarry area are upwards of 400 MT. Quarry operations are expected to take place over an approximate 50+ year period, depending on the demand for aggregate and annual production volumes.

The anticipated processing plant schedule will be 24 hr/day with two 8-hr operating shifts plus one 8 hour maintenance shift, 7 days/week. The plant will operate for nine months of the year weather permitting. The quarry will also operate for nine months of the year. When a ship is present, the marine operations will run 24 hr/day, up to 7 days per week, anytime during the year to accommodate shipping schedules and the time needed to load ships.

The primary components associated with the Project include:

- An unpaved access road from provincial Route 16 into the quarry;
- The quarry and primary crushing area;
- Main feed conveyer from the primary crusher to the processing plant;
- The processing (finishing) plant consisting of secondary and tertiary processing (crushing and washing) and a stockpile laydown area;
- Modular buildings that comprise the administration complex; and,
- A 160 m long marine terminal and load-out facility.

The locations of the primary project components are depicted in **Figure 3.0-1**.

REGION NOVA SCOTIA		PLANT BLACK POINT
DATE: 01/16/2015	SCALE: 1 in = 250 m	DWG. NO. Figure 3.0-1

3.1.1 Access Road

A single private access road to the quarry site, processing plant, and marine terminal will be constructed prior to mining. Vehicular access will be primarily by construction workers during the construction phase and by employees and delivery/service vehicles once the site is operational. The access road will be a 10 m wide unpaved road north from Route 16 along the centerline of easement EA-1 to the southern property boundary, a distance of approximately 800 m (**Figure 3.0-1**). From the southern property boundary, the road will be extended easterly and northerly approximately 2.5 km to access the processing area and marine terminal. The access road will remain inside a 30 m wide buffer around the periphery of the property and, to the extent possible, will be constructed a minimum of 30 m from wetlands.

The access road will be designed to accommodate the anticipated load and size of Project-related vehicles. The intersection of Route 16 and the access road will be designed to meet Nova Scotia Department of Transportation and Infrastructure Renewal (NSTIR) standards. Where possible fill materials required for access road construction will be obtained from within the property. No bridges will be required. Culverts will be installed across any watercourses along the access road in accordance with NSE standards and permit requirements. At this time, only one culvert appears to be needed.

3.1.2 Open Pit Quarry

The site will be developed as an open pit quarry using conventional surface mining methods. The mining cycle will include the following basic actions:

- Loosening and stockpiling of the vegetation, overburden, and loose rock by dozer and/or track hoe equipment;
- Drilling and blasting to establish benches, haul roads, and sumps for stormwater management;
- Loading of loosened rock into haul trucks by track-mounted and/or rubber tired loading equipment; and
- Transportation of the quarried rock by haul trucks to a discharge point at the edge of the quarry for feed to the primary crusher.

Figures 3.0-2 through 3.0-12 show the development of the quarry over time, and list the milestones for each project phase. In general, mining will commence on the north end of the property beginning at the top of the granite hill near the northeast corner of the site. The quarry will be developed initially in a westerly direction before proceeding in a southerly direction to a final grade at or near elevation -30 m asl (i.e., 30 m below sea level). The final quarry footprint will comprise approximately 180 ha.

Overburden will be removed only as necessary to facilitate access to granite reserves. All overburden will be stored on-site for use in the reclamation process or partially used for construction of on-site berms, impoundments and haul roads. The storage locations include the screening berm along the southern portion of the access road and within the open pit. Once the

vegetation and overburden have been removed, drilling and blasting will be used to mine material and establish benches along the rock face.

Holes will be drilled into the rock to receive the explosives used for blasting. In general, the rock will be blasted along specific drill patterns that will maximize rock breakage and minimize wasted energy. It is anticipated that blasting will occur 30 days per year during the initial project phases, and increase to a maximum of about 200 days per year at full operation. All blasting activities will be conducted by a licensed contractor. Blasting will not be undertaken on Sundays or statutory holidays.

Freshly mined rock will be transported to and reduced in size by a primary crusher located on a bench on the east side of the quarry (see **Figure 3.0-1** for location). The crushed material will then be transported via conveyor to the processing plant (see Section 3.1.3 for a detailed description of processing).

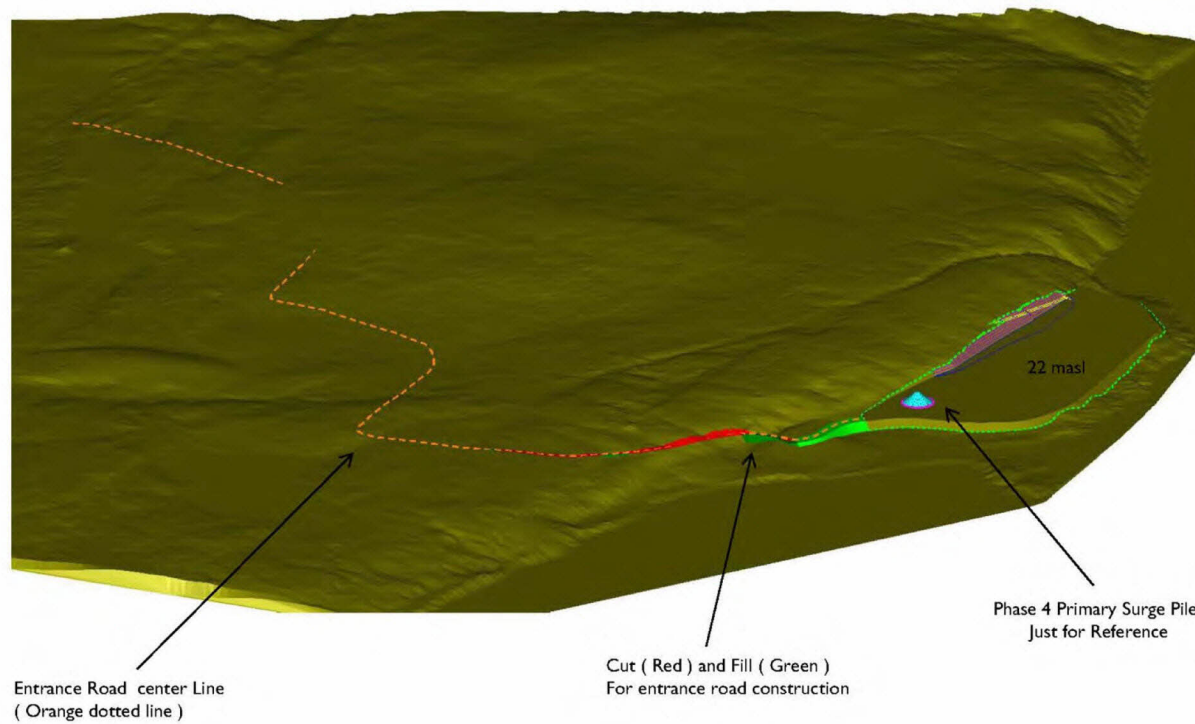

As quarry development progresses, essential milestones will be established to ensure sufficient access to reserves to meet production requirements. The preliminary milestones include:

- Access road and plant pad development;
- Establish haul ramp from plant pad to an elevation of 52 m asl (primary dump elevation);
- Locate primary crushing station;
- Construction of up to a 16.9 million gallon (64,000 m³) temporary sump;
- Establish haul ramp down to an elevation of 22 m asl to prepare for construction of main pit sump; and
- Construction of up to a 102 million gallon (386,000 m³) permanent sump.

During the initial phases, the materials mined will be utilized during the plant development and construction.

3.1.3 Processing Plant

Based upon the preliminary design, there will be five phases of the processing plant ranging from an initial portable circuit utilized for site development to a large fixed plant capable of producing an anticipated peak production of 7.5 MT. Process flow diagrams for each phase are included as **Figures 3.0-13, 3.0-14 and 3.0-15**. A description of each phase is given below.

THIS DRAWING IN DESIGN AND DETAIL IS THE PROPERTY OF VULCAN MATERIALS COMPANY AND MUST BE RETURNED UPON DEMAND. THIS DRAWING MUST NOT BE COPIED, REPRODUCED, OR IN ANY MANNER DISSEMINATED.	

Phase 1, Figure 3.0-16

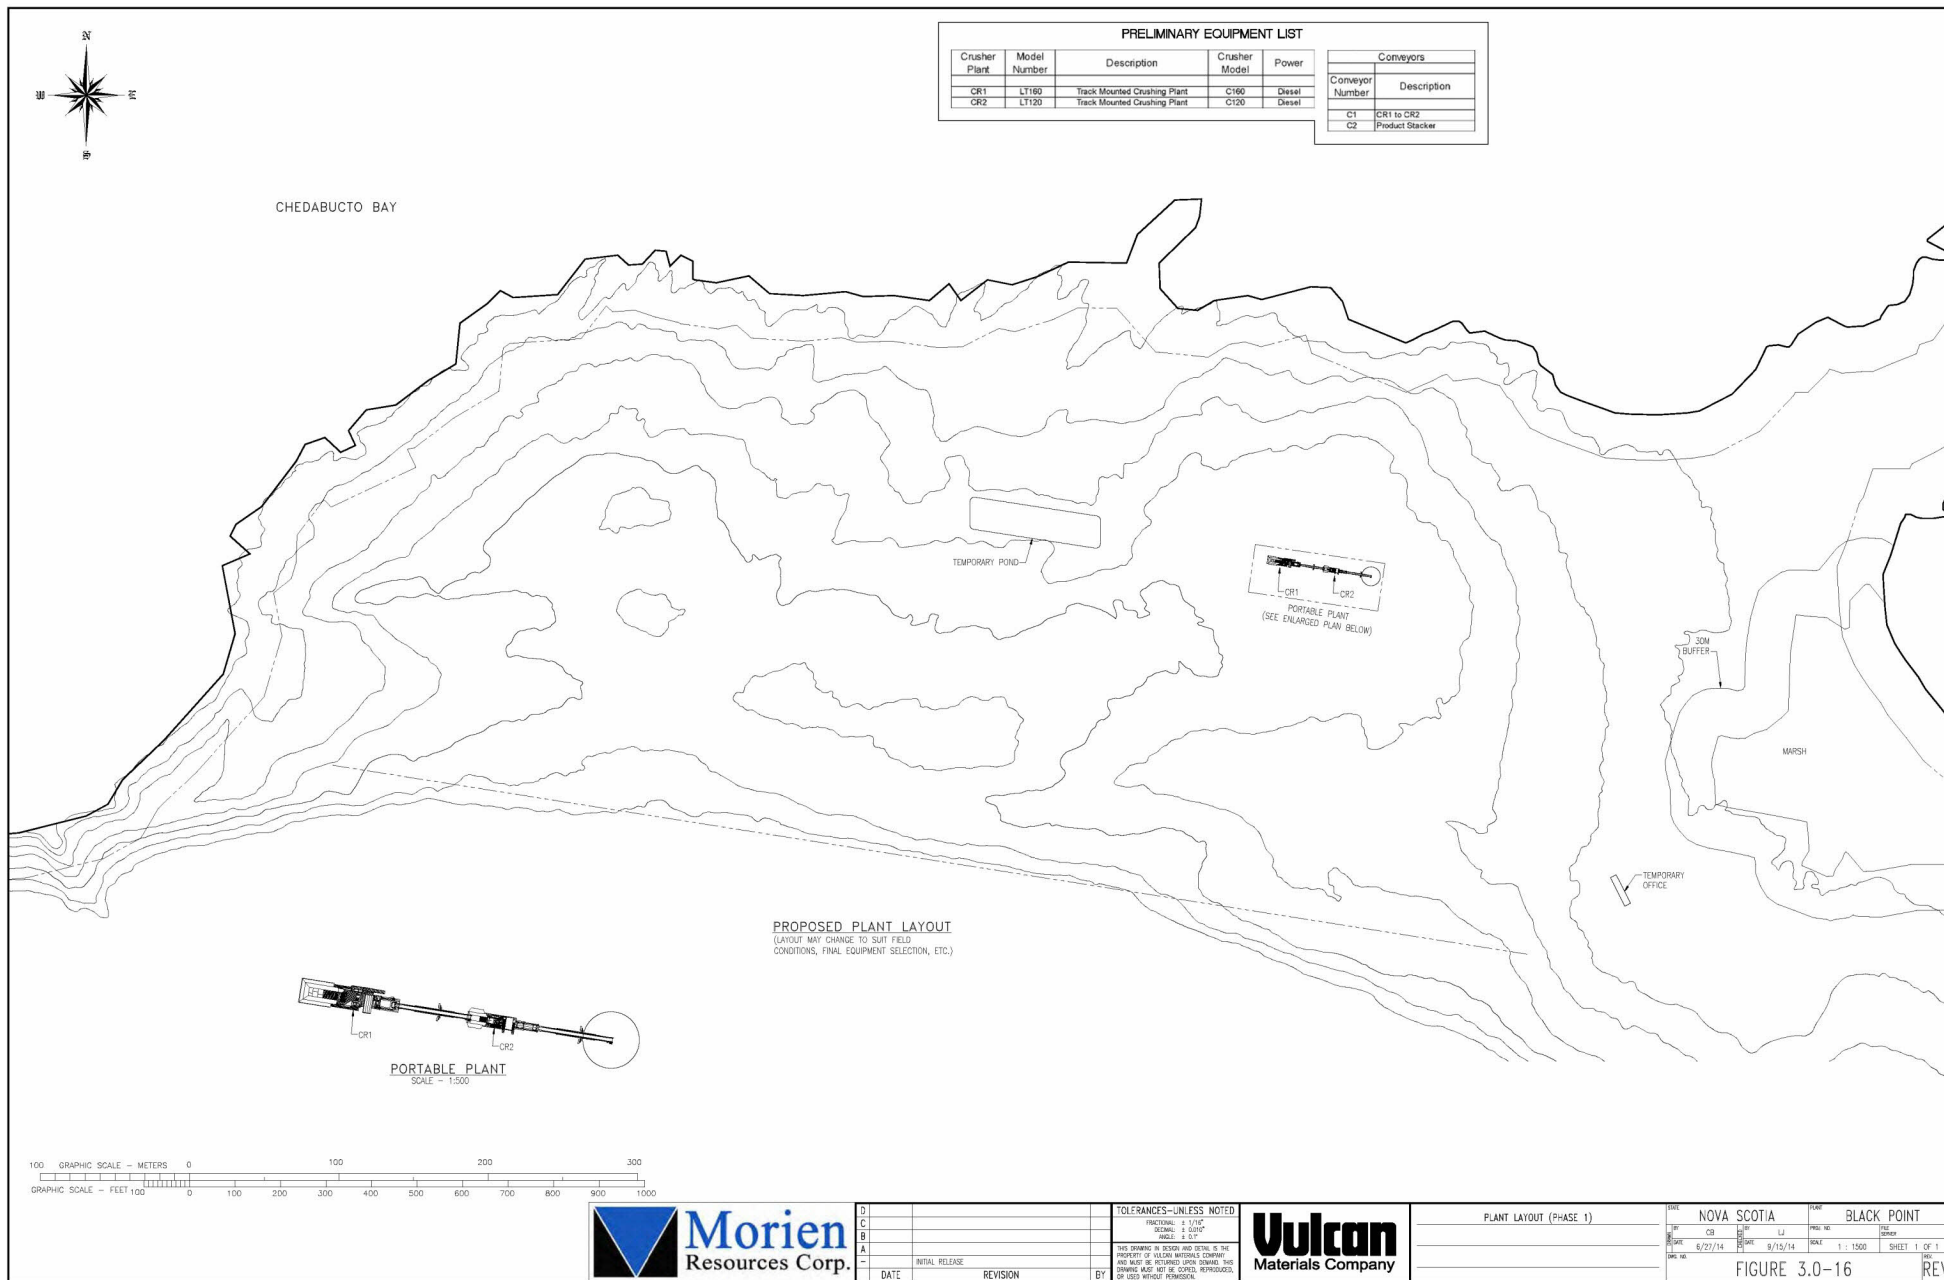

Major components:

- Two portable track mounted primary crushing plants that include vibrating grizzly feeders.
- Conveyors.

A small portable or mobile plant with a capacity up to 1,000 tons per hour (TPH) will be utilized for initial plant site development. This plant will produce a coarse fill material for site development needs (i.e., road, berm and platform construction). Power for the plant will be provided by diesel powered generators with capacities of either 200 kW or 525 kW depending on whether electricity is available to power the non-motive portion of the plant.

During development of the plant site situated on the lower coastal platform, the grade will be sloped away from the coast and wetlands and toward stormwater retention basins first located near the center of the coastal platform (Figures 3.0-16) and in later phases situated at the foot the cliff (**Figures 3.0-17 and 3.0-18**). These basins are designed to retain stormwater to allow for clarification prior to discharge the marine environment, if needed.

In this plant, blasted material will be trucked to the mobile plant and dumped adjacent to the primary module. A loader will then feed the material into the processing plant. The coarse fill material will be stockpiled by conveyor.

Phase 2, Figure 3.0-17

Major components:

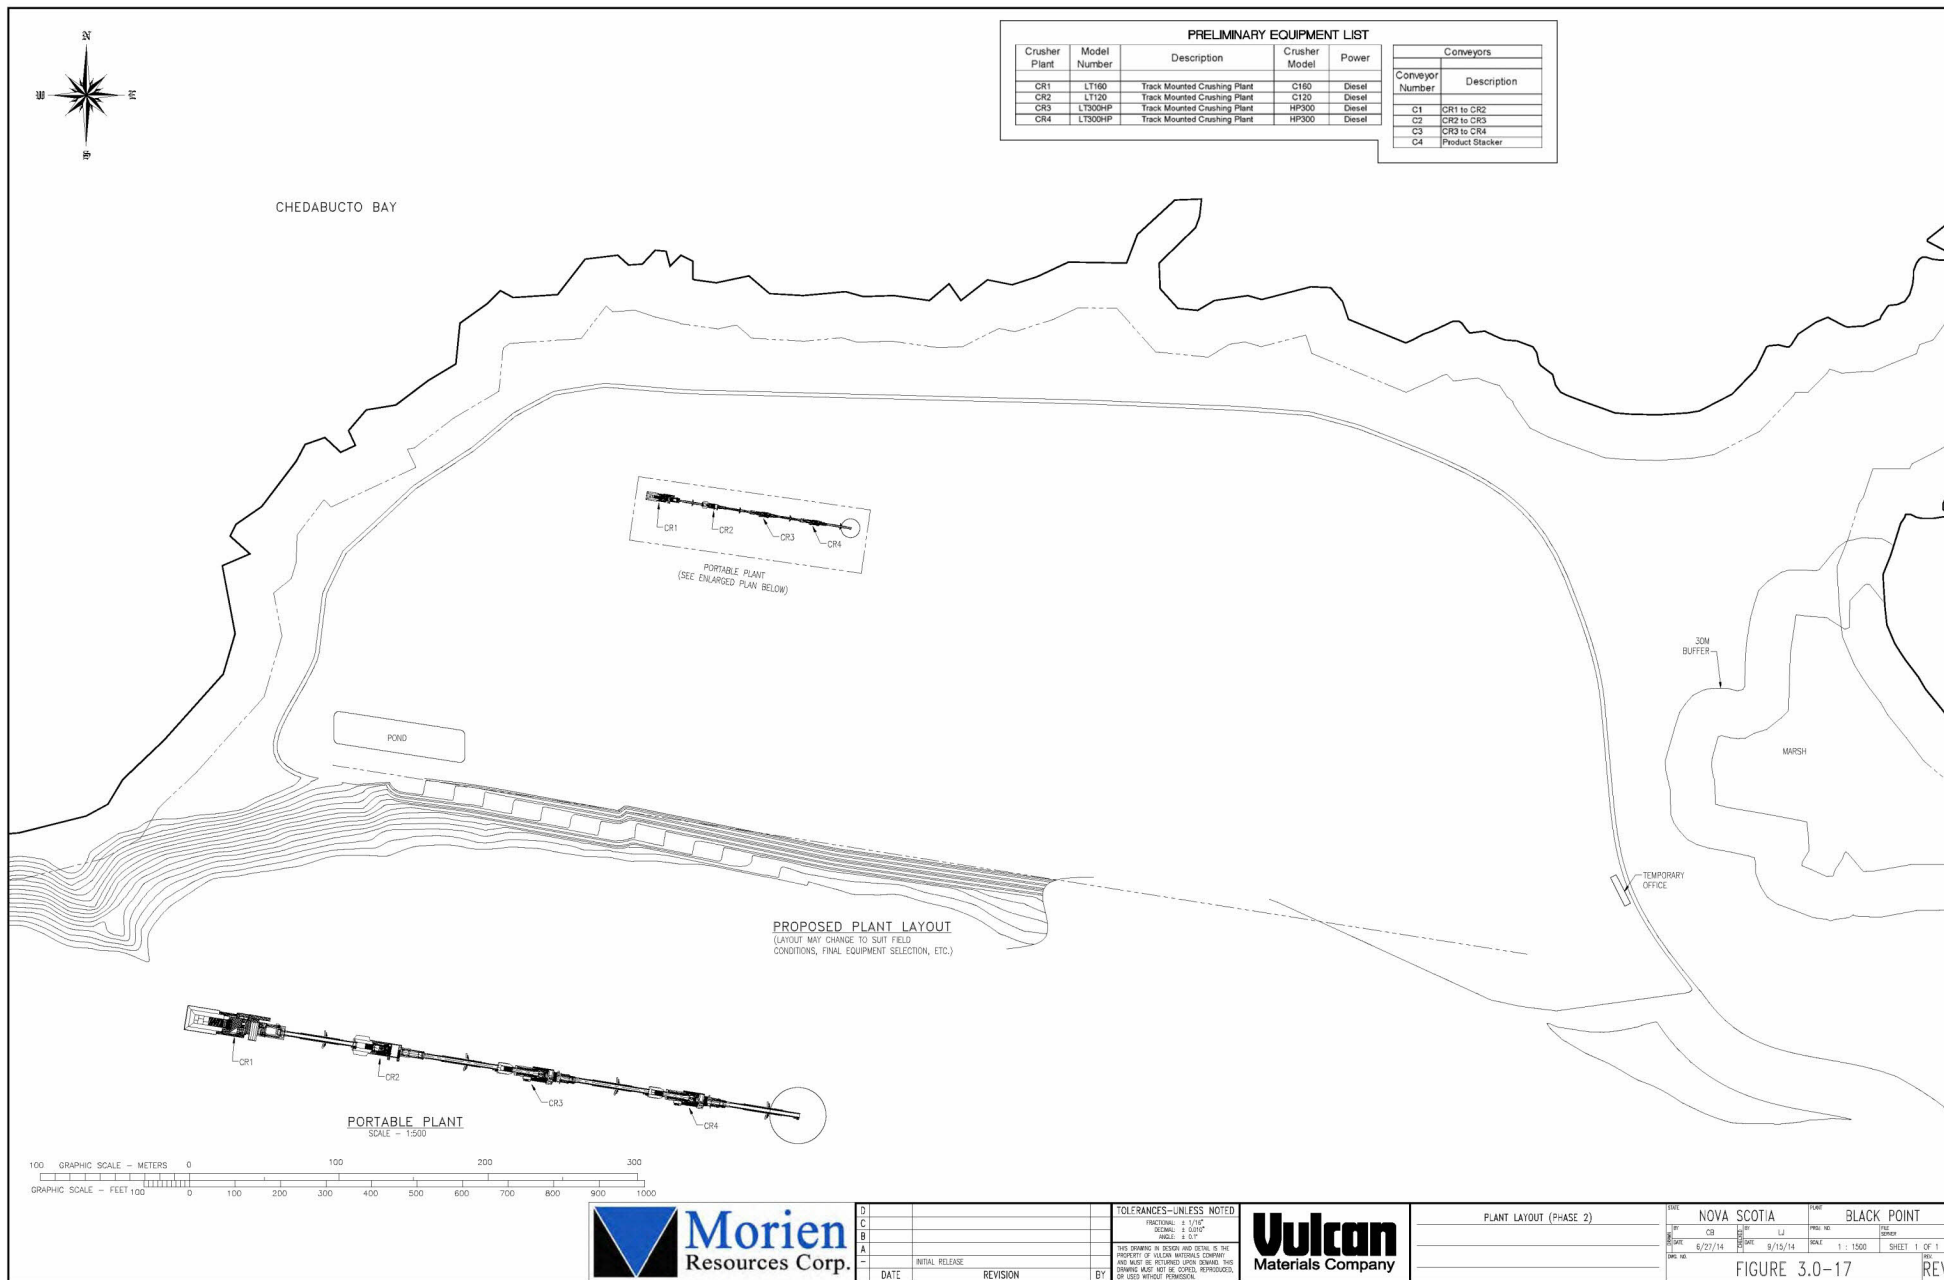

- Phase 1 equipment described above.
- Two portable track mounted secondary crushing plants that include vibrating feeders.
- Conveyors.

In the second phase plant, two additional track mounted crushing modules will be added to the Phase 1 equipment; the modules will have a similar capacity to that described for Phase 1. This plant will produce a fine graded fill material for final site development needs. Power for this plant will be provided by diesel powered generators built into the track mounted crushing units.

During final development of the site, the grade will be sloped away from the coast and wetlands and toward a permanent stormwater retention basin built against the cliff. This will prevent uncontrolled stormwater discharges to the marine environment.

Marine terminal construction is expected to begin during Phase 2 as described in Section 3.2.6.

Operation of this plant will be identical to that of the Phase 1 plant. The fine graded fill material will be stockpiled by conveyor and no washing of aggregate will occur during Phase 1 or Phase 2. All material produced will be a base or crusher run product.

Phase 3, Figure 3.0-18

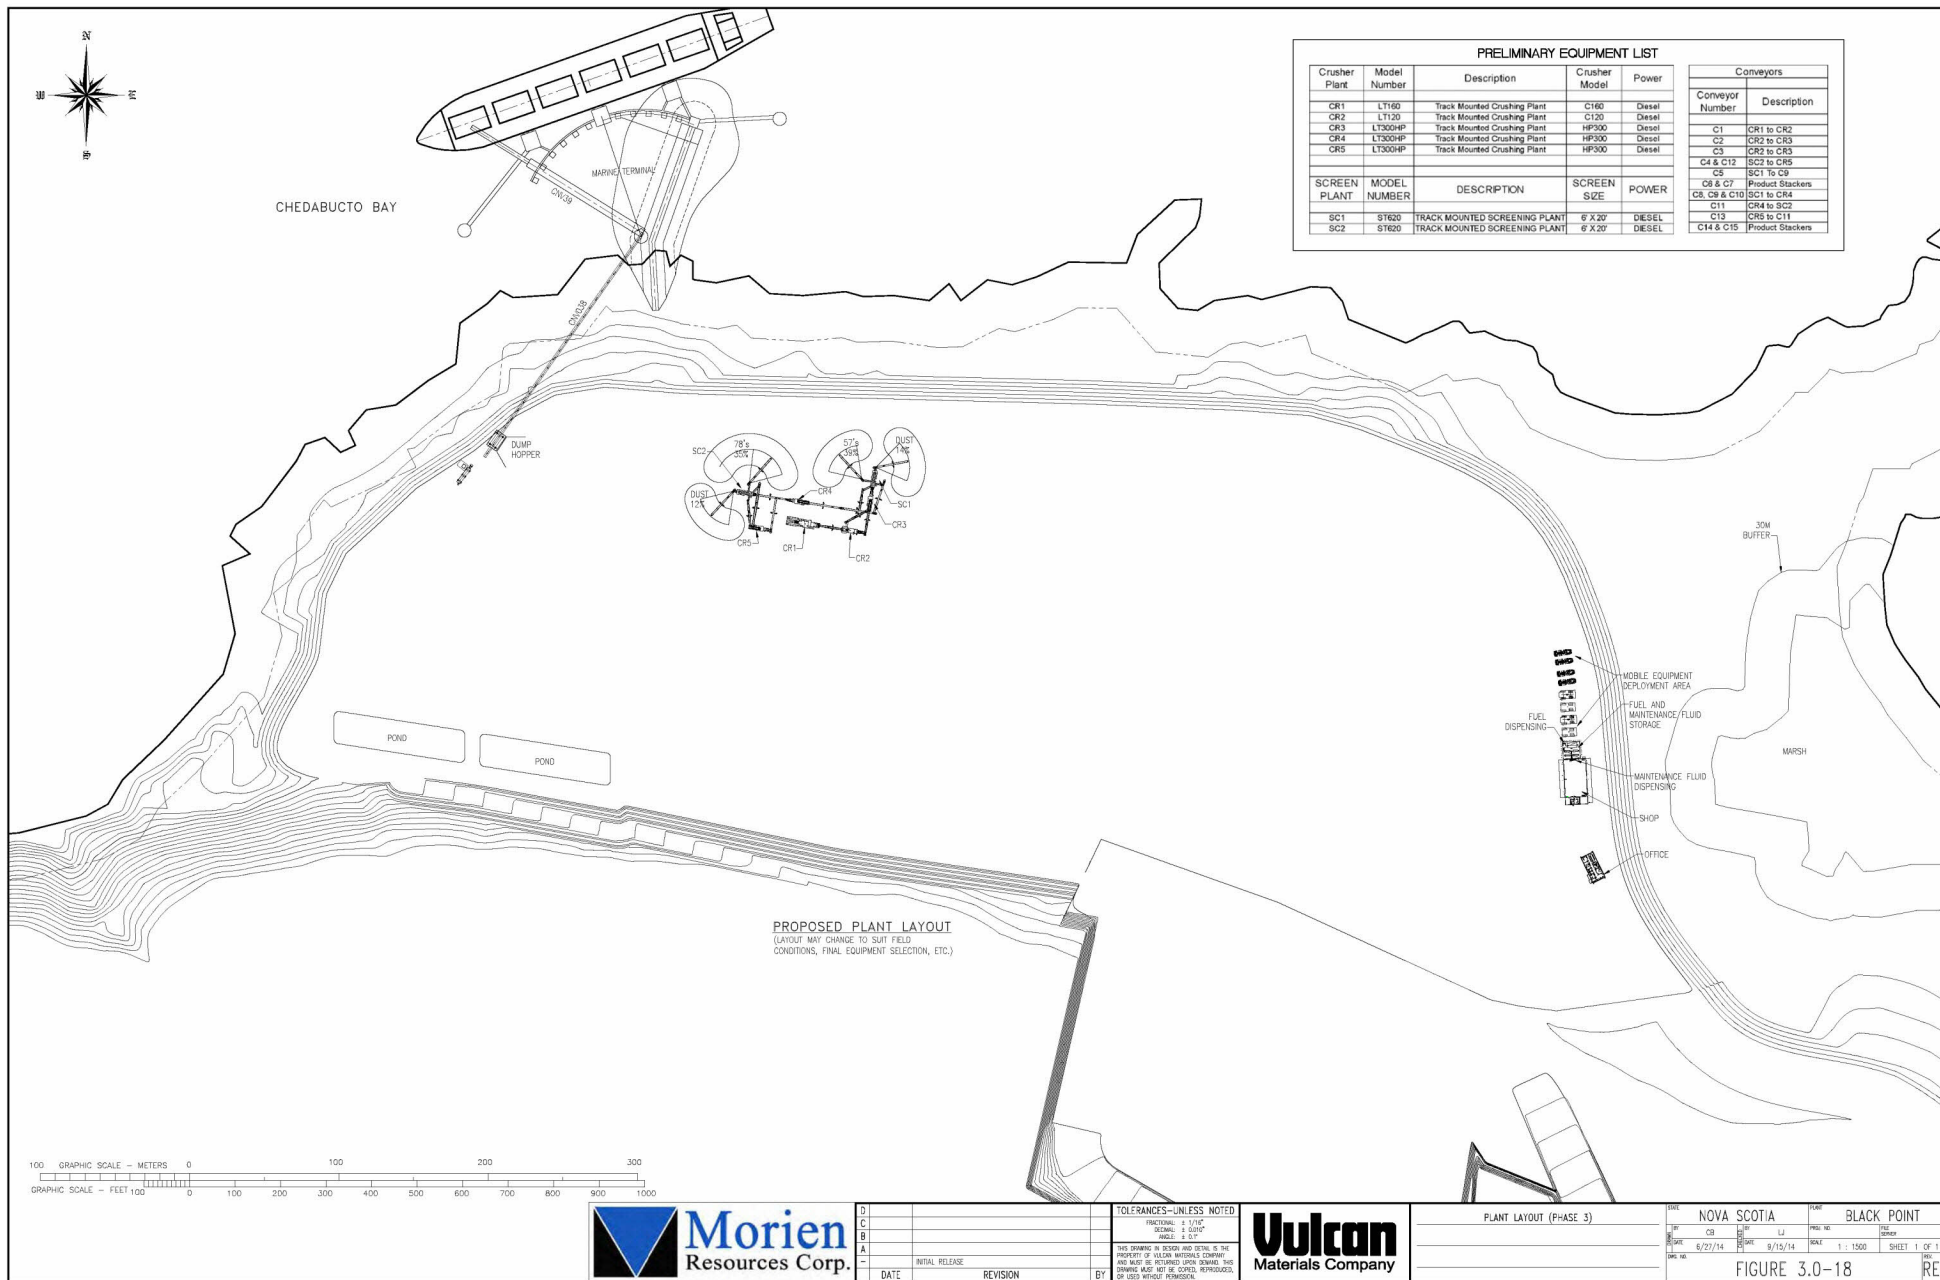

Major components:

- Phase 2 equipment described above.
- Two additional portable track mounted screening plants.
- One track mounted tertiary crushing plant with a belt feeder.
- Conveyors.

After the processing plant site has been developed, additional mobile units will be added to begin production to meet the initial sales demand. Power for the additional units will be supplied by diesel powered generators with combined capacity of 260 kW in addition to the existing generators identified as in Phases 1 and 2. Production during Phase 3 is expected to be approximately 500 TPH. This plant will be replaced by a larger fixed plant over time as the sales demand dictates. This approach is intended to save capital during the early years of the Project.

Operation of the Phase 3 plant will be similar to that of the earlier phases. In this plant, various products will be stockpiled via conveyor and trucked to the marine terminal. The conveyor feeding the ship loader will include a loadout hopper that can be charged with a plant loader.

The portable plant will be located in a portion of the plant site that will allow construction of the Phase 4 plant.

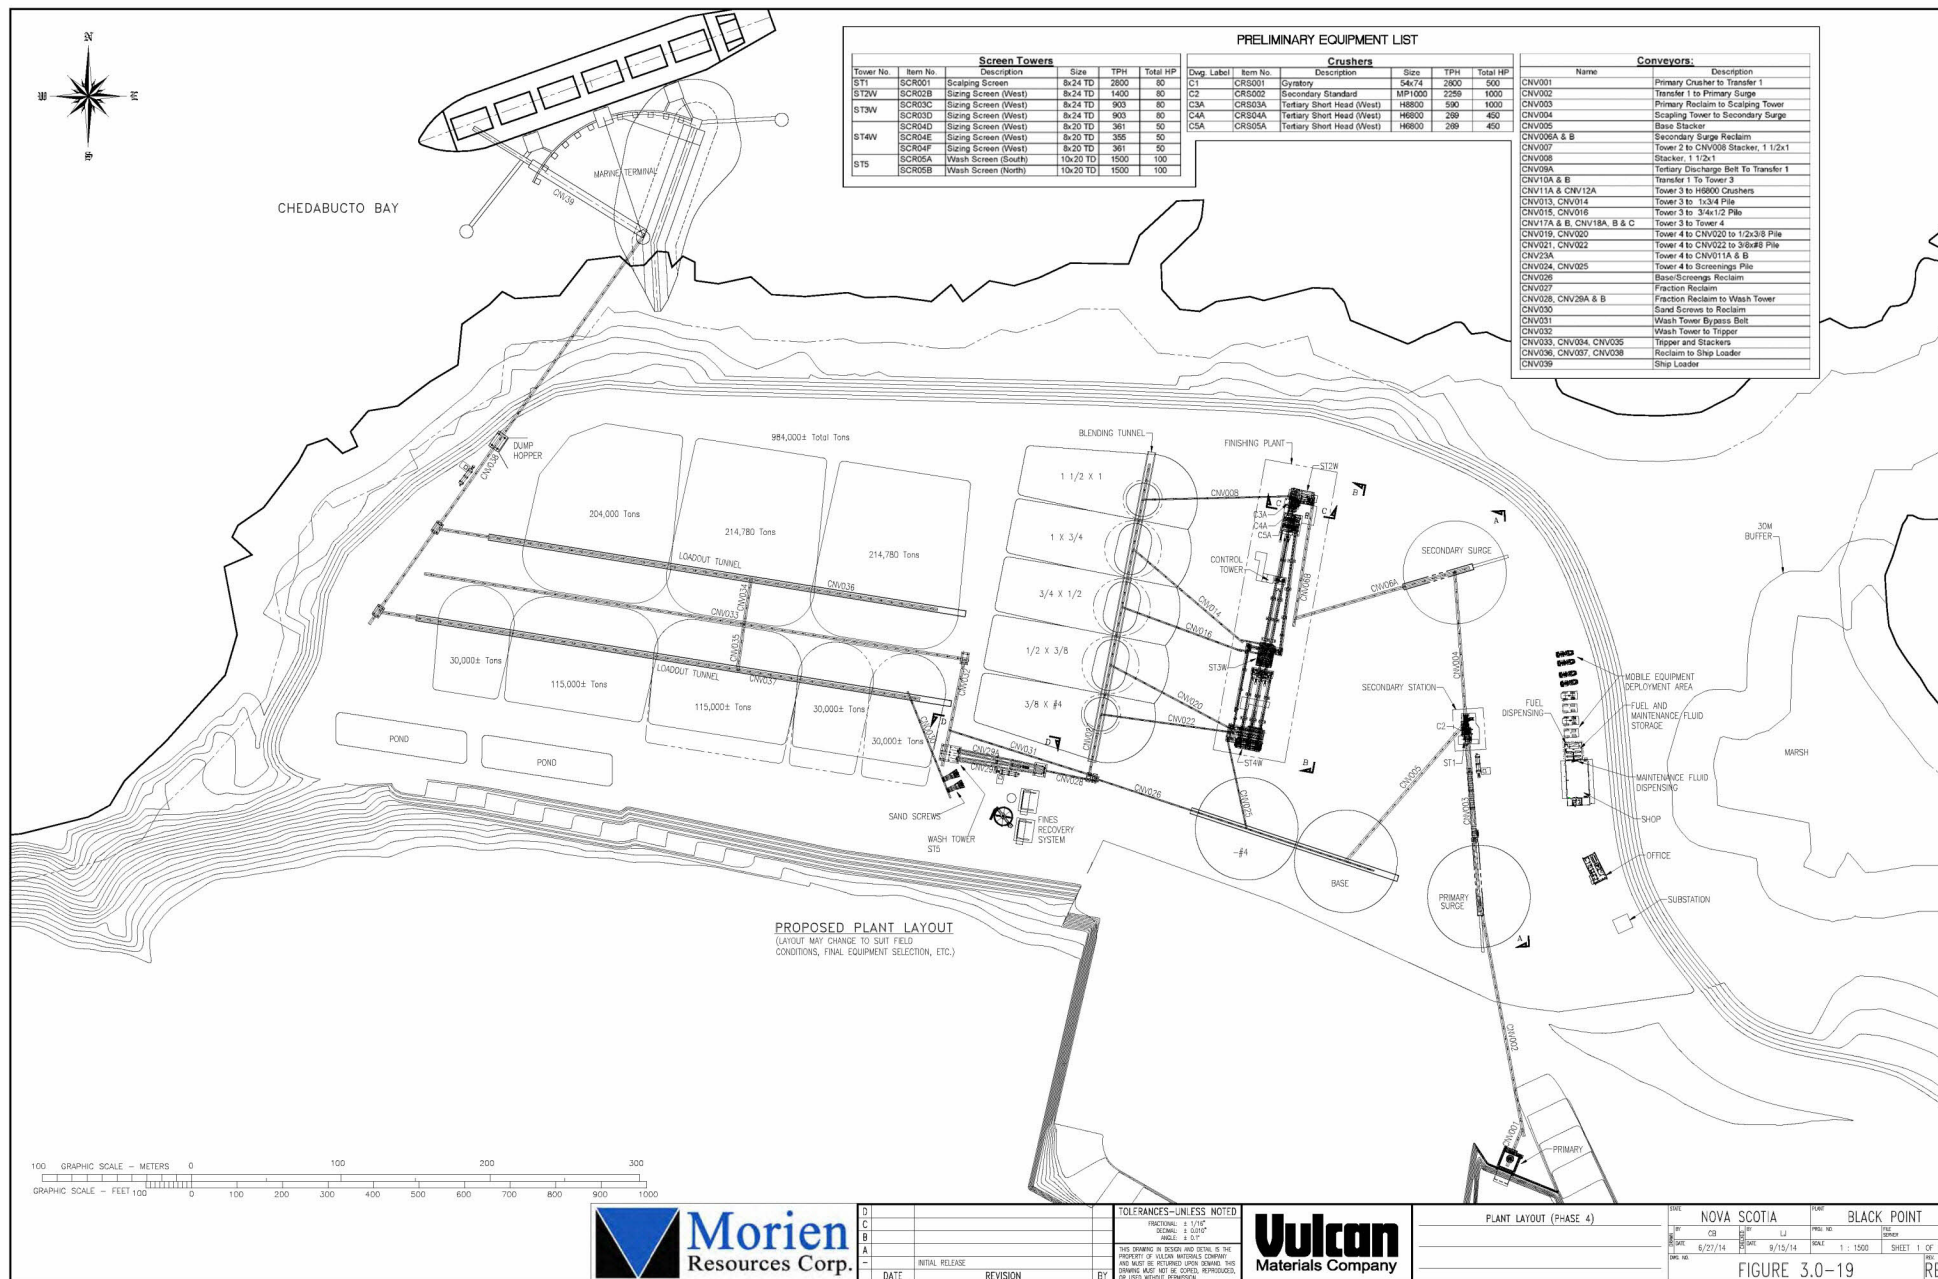

Phase 4, Figure 3-19

Major components:

- Primary gyratory crusher.
- Primary surge reclaim tunnel.
- Scalping screen.
- Secondary cone crusher.
- Secondary surge reclaim tunnel.
- Six sizing screens.
- Three tertiary cone crushers.
- Conveyors.
- Vibratory feeders.
- Base/screenings reclaim tunnel.
- Fractionated products reclaim tunnel.
- Two wash screens.
- Fines recovery system.
- Two sand screws.
- Two loadout reclaim tunnels.
- Marine terminal.

When the sales demand dictates a higher production rate, the mobile plant will be replaced by a larger fixed plant. The plant will have a flexible design that will allow it to be expanded as the market demand increases. The initial fixed plant will have the capability to produce up to 1,400 TPH through the tertiary plant.

In this plant, blasted material will be trucked to the primary crusher where it will be dumped into the primary hopper. There it will be crushed and conveyed to a primary surge pile located near the “secondary” where it will be fed into the plant. As the material is processed with further crushing and screening, it will be conveyed to product piles that are located over “reclaim” tunnels, that is, tunnels equipped with conveyor systems that allow the products to be moved. Products can then be reclaimed to the wash tower for rinsing or bypassed around it. Material will then be stockpiled over the loadout reclaim tunnels that will convey product to the marine terminal.

The plant layout is designed in consideration of safe operational needs along with best practices developed over many years. The plant will be designed to minimize airborne dust emissions by utilizing built-in wet suppression for dust control. All structures will be designed according to appropriate building codes and engineering standards. Electrical power for the plant will be provided via Nova Scotia Power Inc. as described in Section 3.1.6.

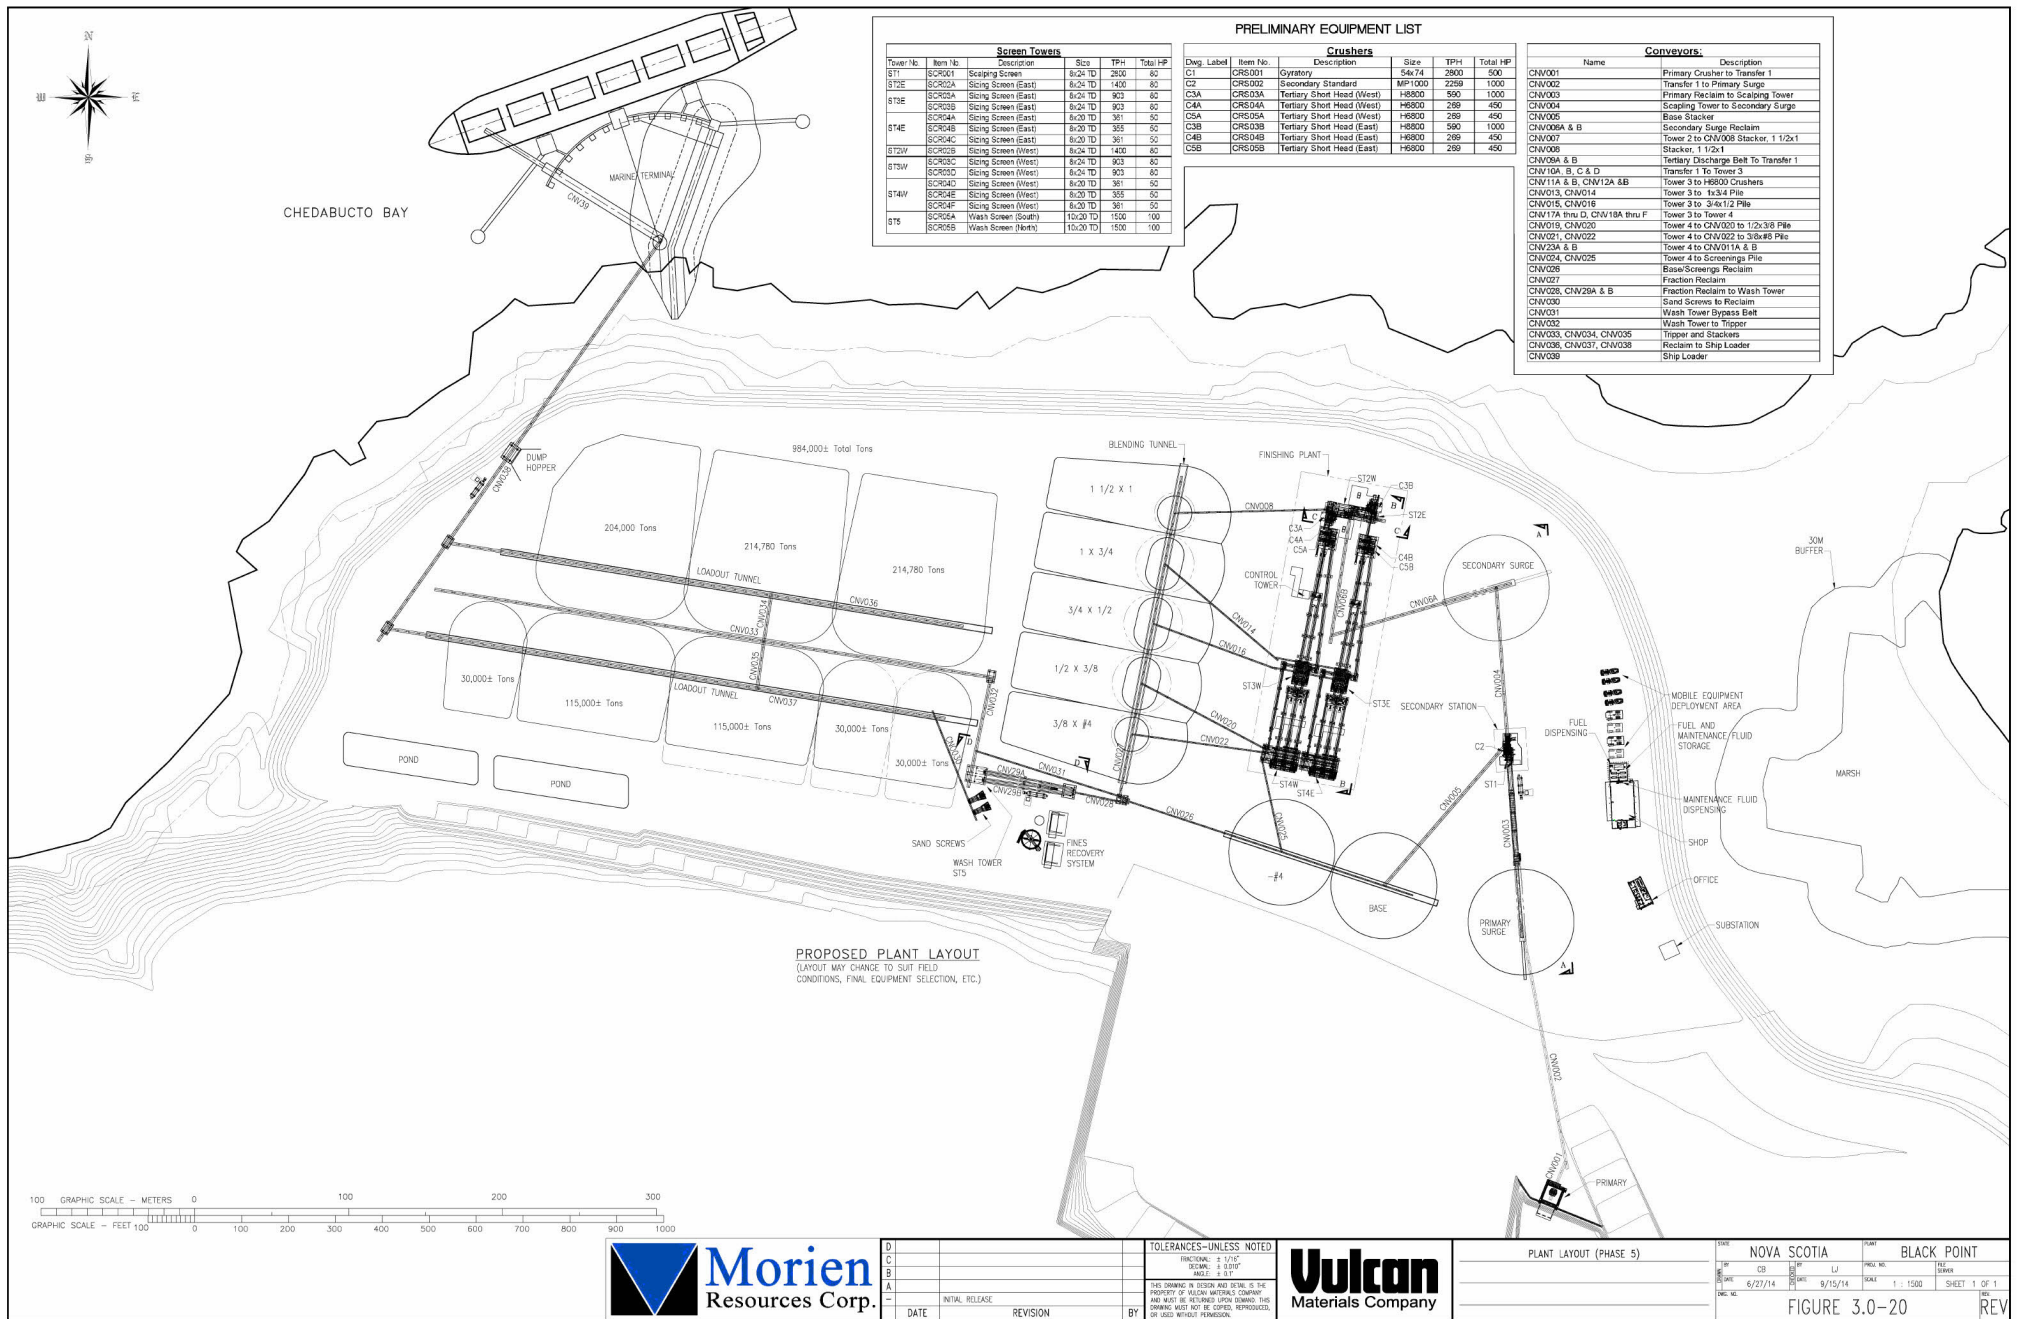

Phase 5, Figure 3-20

Major components:

- Phase 4 equipment described above.
- Six sizing screens.
- Three tertiary cone crushers.
- Conveyors.
- Vibratory feeders.

As the sales demand increases and production rates approach the limit of the initial fixed plant, the final phase will be initiated. This plant will upgrade the tertiary portion of the Phase 4 plant by installing a parallel tertiary processing circuit. Figure 3.0-21 provides plant elevations for the Phase 4 and 5 plants. Production through the finishing plant will be increased to 2,800 TPH.

Processing and loadout of the material will be identical to the Phase 4 plant but with a higher capacity. The parallel circuit will be identical to the original tertiary to minimize design time and costs. The layout will be located to minimize any operational disruptions due to the expansion.

FIGURE 3.0-21		REV	

3.1.4 Stockpiles, Overburden and Crusher Fines

The processing plant site is approximately 28 ha in size and occupies the northern section of the 354.5 ha Project site along Chedabucto Bay (**Figure 3.0-1**). This area will be used for processing (e.g. secondary and tertiary crushing, screening, washing and conveying), as well as stockpiling aggregate products, equipment, fuel and material storage, ship loading and administrative buildings.

The area will contain two ponds beginning in Phase 3, located on the western edge of the plant site against the cliff. Each pond will be sized to hold approximately 6,100 m³. One of the ponds will be dedicated to stormwater retention and will be dry most of the time, while the other will be used to supply process water for washing and dust control. During Phase 1, temporary ponds will be utilized as required to manage stormwater. In Phase 2, one of the permanent ponds will be constructed and dedicated to stormwater retention.

This portion of the site will include two surge piles, various aggregate product piles (fractionated, screenings and base material) and approximately 1,000,000 tons of product ready for shipment. The plant layout and water system will be designed to minimize airborne dust emissions by employing wet suppression for dust control.

Storage locations of overburden and organic materials will be selected as part of the detailed site engineering. For the purposes of the EIS, overburden storage is shown in a screening berm along the southern property boundary and in various designed piles inside the pit boundary (see **Figures 3.0-2 through 3.0-12**).

3.1.5 Administrative Buildings

Approximately 2.5 ha will be dedicated for an administrative area and will be located on the eastern edge of the plant site (**Figure 3.0-18**). In this area, two buildings (modular or fixed) will be erected. One will contain offices and the administrative functions while the other will contain facilities for on-site workers such as a locker/shower room, washroom, first aid station, lunchroom, quality control laboratory and shop. This area will also include a site to store fuel and other maintenance fluids. Mobile equipment will be parked adjacent to the shop.

3.1.6 Transmission Line Tie In

Electrical power will be required for buildings and the operation of equipment (pumps, conveyors, crushers, screens and ship loading). Electrical demand will vary over the life of the Project. During Phases 1 and 2, a 200 amp service will be sufficient to provide power for the buildings. Diesel powered generators will provide the power for the processing plant and equipment during this time. The 200 amp electrical service is expected to be provided from a 25 KV high voltage distribution line running along Route 16 and operated by NSPI. The line will be routed adjacent to the entrance road with a pole mounted transformer located near the temporary office as shown on **Figures 3.0-16 and 3.0-17**. Due to the line location along the disturbed portion of the entrance road, no additional environmental effects are anticipated.

Once sales demand dictates a larger plant, a tie-in will be made to the 69 KV high voltage line that runs along the southern boundary of the Project site. This line will also be routed adjacent to the entrance road and will terminate at the substation as shown on **Figure 3.0-19**. Again, the

line will be routed along the disturbed portion of the entrance road so no additional environmental effects will result. All power to the plant will be routed underground from the substation and these lines will remain within the Project property. The transformer sub-station will be required to reduce the voltage for the quarry. The peak electrical power demand for the site is estimated to be between 10,000 and 12,000 horsepower (i.e., 5.0 to 6.0 MW). Following discussions with NSPI, the tie-in to the high voltage line and the sub-station are expected to be provided and owned by NSPI. Temporary diesel powered generators may be needed until such time as the sub-station and transmission link are complete.

3.1.7 Marine Terminal

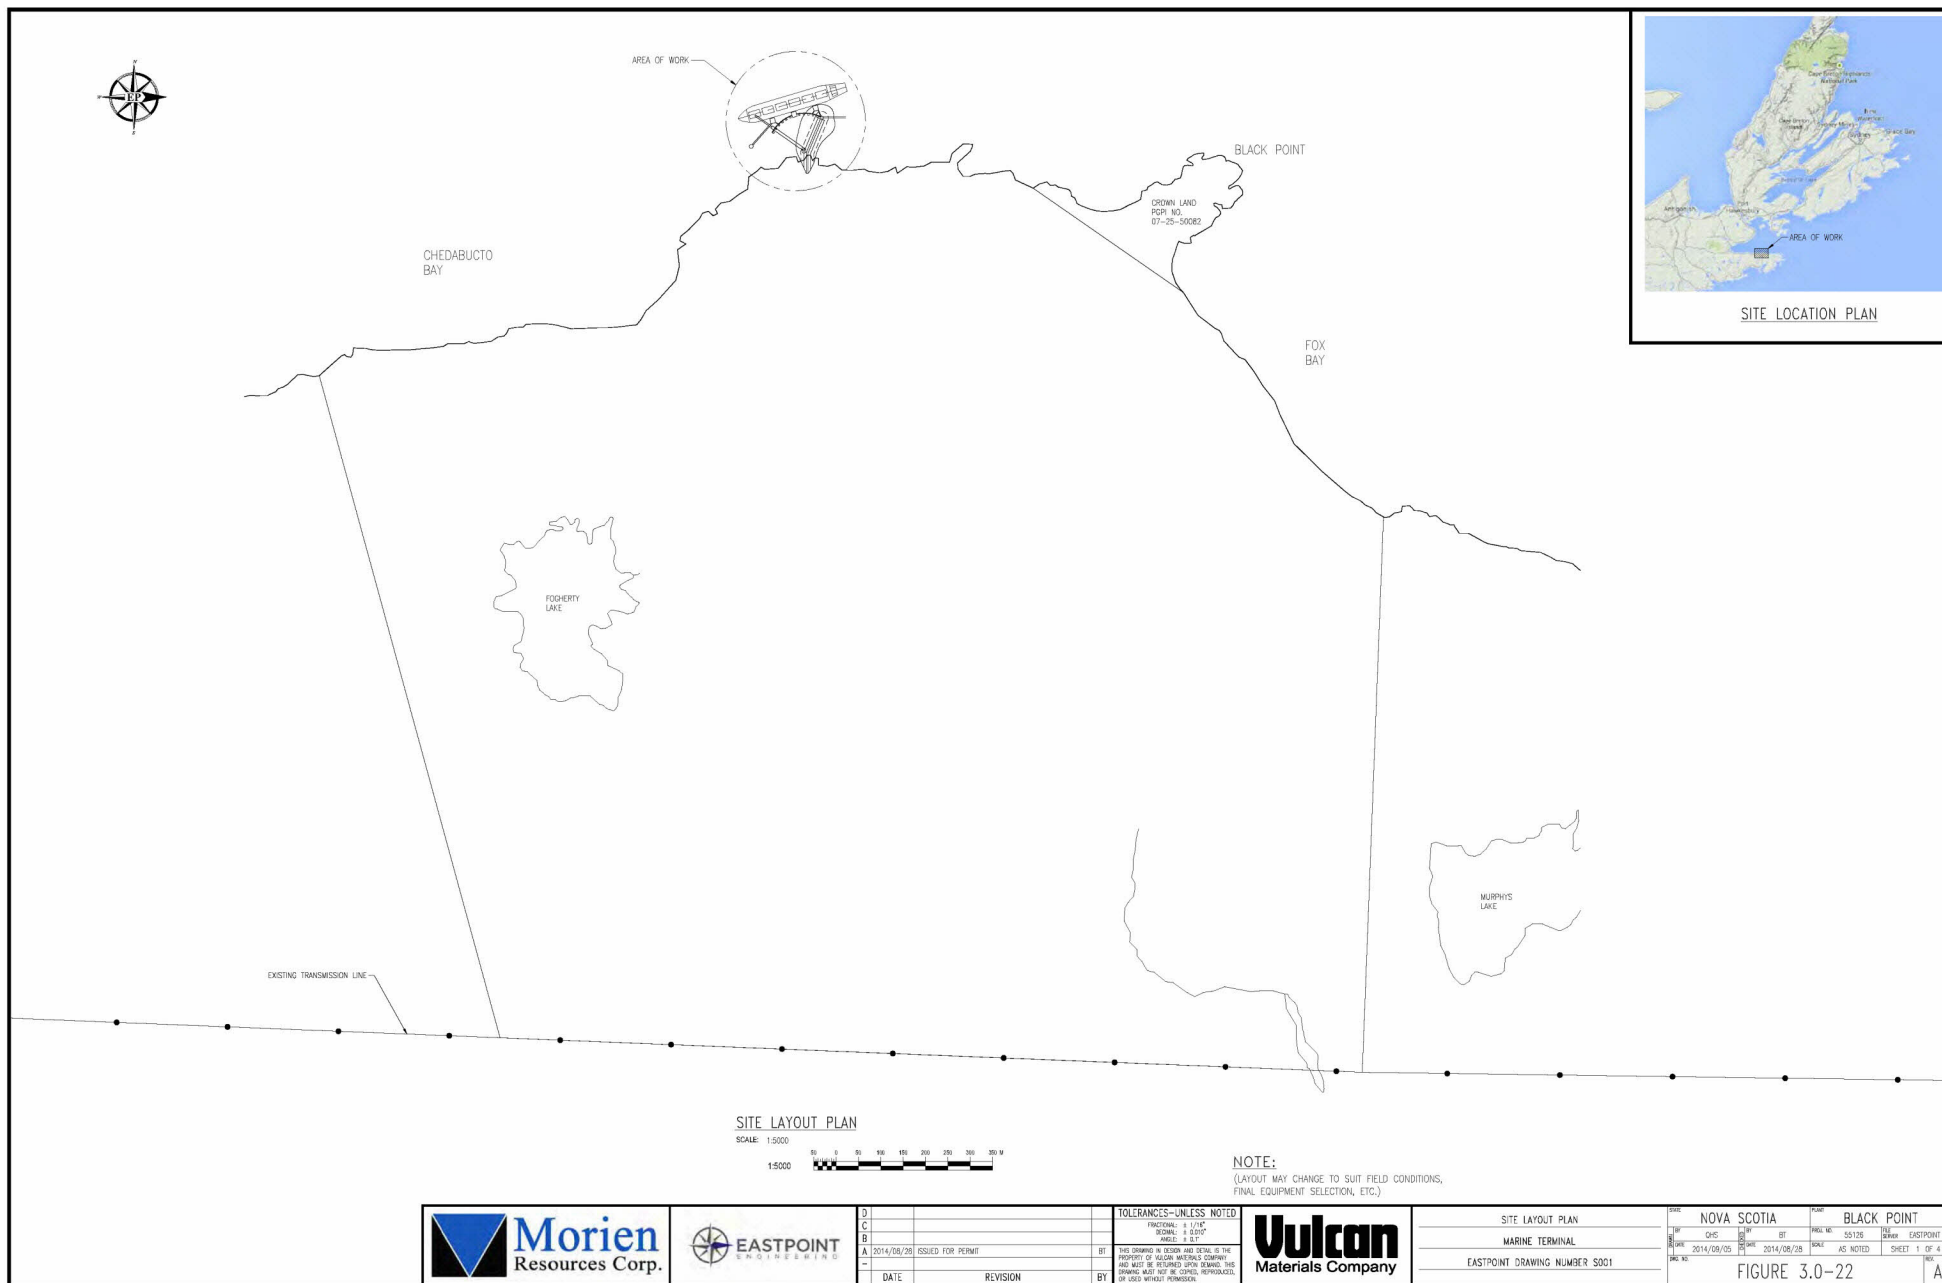

Based upon preliminary engineering, a rubble mound approach (where conveyors and related infrastructure are installed on a stone breakwater constructed of coarse rock extending from the shore) will be utilized in the design of the marine terminal. Caissons and mooring dolphins will be used for berthing the ship. The rubble mound will comprise the primary structural element of the terminal and will provide stability for the shiploader during operations as well as a means of egress for maintenance. Preliminary engineering drawings for the terminal are shown in **Figure 3.0-22 through Figure 3.0-25**. The major components of the facility are:

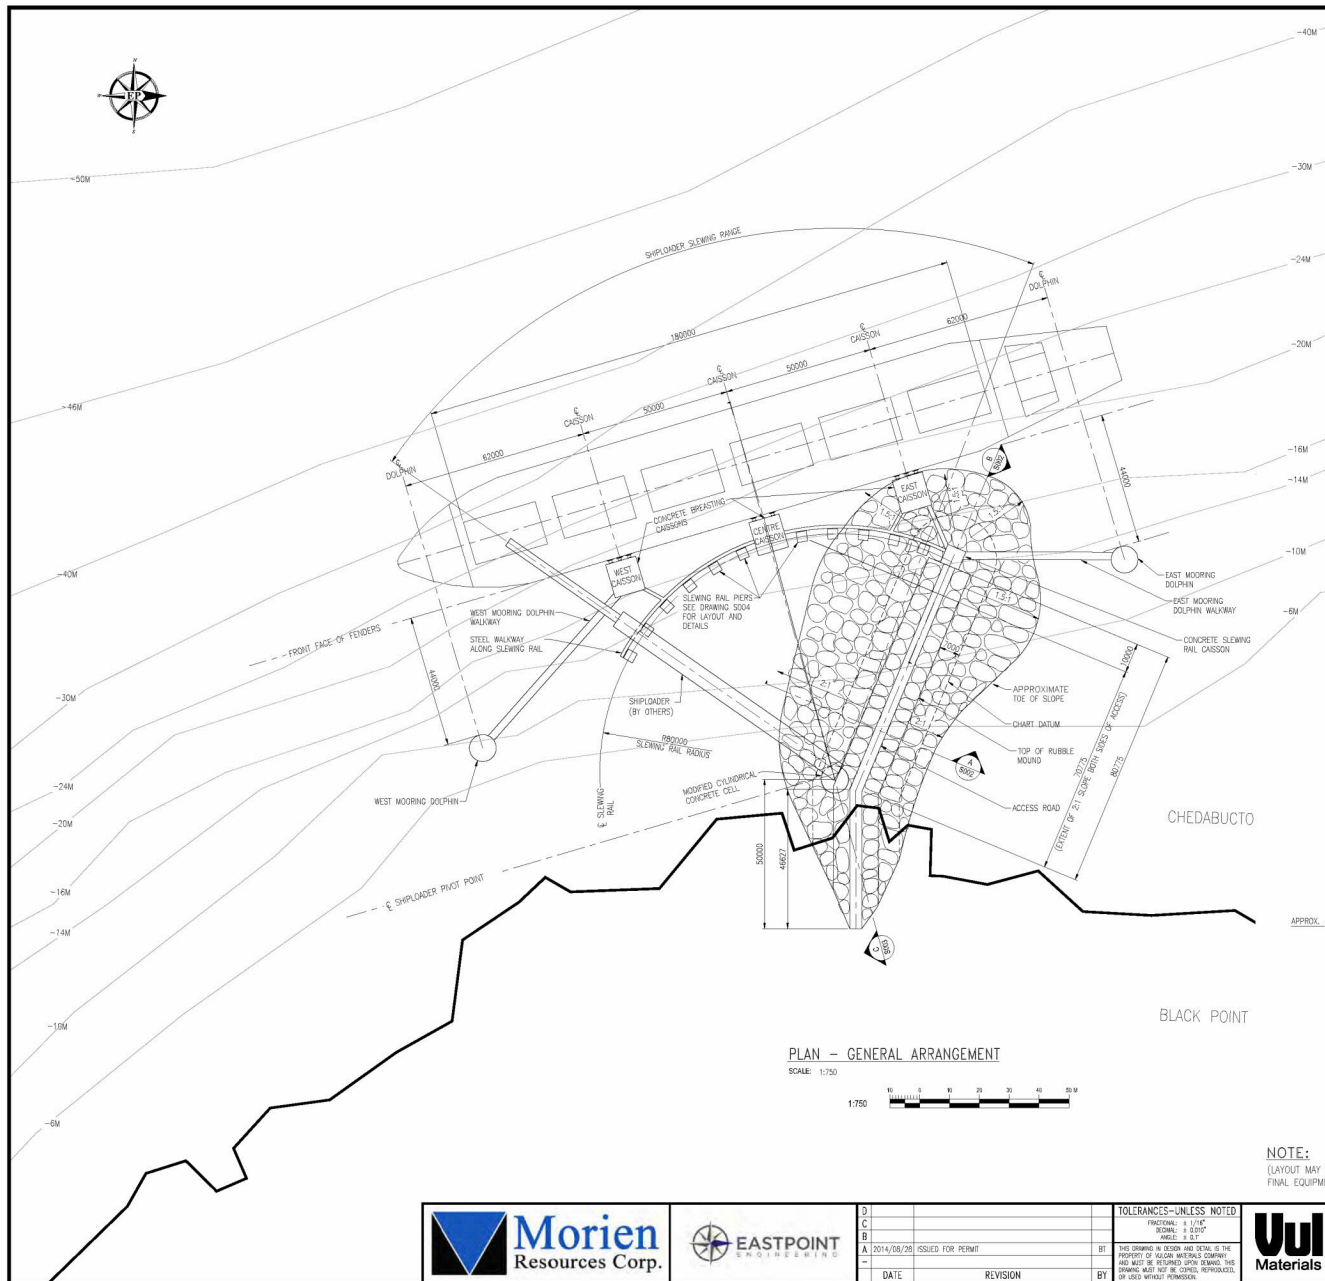

- Three breasting caissons used for berthing the ship.
- Two mooring dolphins.
- Eleven slewing rail piers that support the slewing rail, which in turn allows the shiploader to move in an arc.
- One slewing rail caisson to support the slewing rail.
- Shiploader pivot point caisson, which provides the lateral stability of the shiploader.
- Rubble fill with an access road for maintenance.
- The shiploader arm that delivers aggregate product to the ship.

The shiploader is a telescoping system approximately 136 m long when fully extended. It is capable of loading vessels up to 70,000 deadweight tons (DWT) without warping (shifting) the vessel. The shiploader transports material from the land based conveyor into the ship and will have a loading capacity approaching 5,000 TPH. Lighting will be shielded to direct light down onto the conveyor during night operations. Navigational lighting will be provided as required by Transport Canada.

The rubble mound portion of the terminal will be approximately 160 m in length as shown in **Figure 3.0-24**. It will be constructed with a clean rock-filled base, armour stone protection on all sides and include a crushed stone surface. This structure will have a seafloor footprint of approximately 11,078 m² which includes the combined seafloor surface area occupied by the rubble fill, caissons and dolphins. The dolphins and piles will be designed and constructed to withstand the horizontal loads associated with the berthing of vessels as well as the environmental loads (wind, waves, etc.) present.

Shipping will be contracted to a third party and no waste disposal, deck washing or fuelling will occur at the marine terminal.

3.1.8 Waste Water Treatment System (Other Utilities)

Other utilities will include domestic water supply that will be supplied by drilled groundwater wells, and a waste water or sewage disposal system to facilitate the needs of on-site workers (please see Section 3.3.7). Propane tanks may also be installed for heating or other functions.

3.2 CONSTRUCTION PHASE

3.2.1 Construction Activities

When construction begins, there will be two main activities: site preparation and plant construction (see Table 3-1). Site preparation will come first. A temporary crushing facility will be employed to produce the crushed stone needed to surface the access road and level the plant site for the site preparation. The permanent plant will be constructed as soon as sales warrant. Site preparation and construction activities are described below.

Site Preparation

- Vegetation removal and stockpiling²;
- Entrance and infrastructure road clearing and initial construction;
- Erection of the temporary crushing facility;
- Surveying and delineating plant site, road right of ways, and protected areas buffers;
- Blasting and rock crushing to produce surfacing stone for roads and the Plant site;
- Plant site grading to create suitable plant/laydown area with controlled drainage;
- Erosion and sedimentation control installation, including stormwater management pond(s);
- Site access control including gates, and earthen and boulder berms; and
- Excavation of sanitary and process waste collection disposal system

Construction

- Employ a modular portable plant to process stone during early phases;
- Undertake blasting and crushing to produce additional surfacing stone;
- Create trenches for electrical conduits;
- Construct concrete foundations for processing plant equipment;
- Install an electrical substation and supporting power network;

² Vegetation removal will be undertaken on an as needed basis, rather than over the entire site at project start up. Vegetation removal will occur outside of the breeding bird season.

- Build temporary and permanent office locations;
- Pour concrete pad and containment area for petroleum products; and
- Excavate additional stormwater management pond(s)

Best Management Practices

Guidelines for construction and site grading have been created by the Province and will be employed.

- Sedimentation and Erosion Control Handbook (NSE 1988);
- Watercourse Alteration Protection; Erosion Protection; Wharves (NSE 2013b); and
- Nova Scotia Pit and Quarry Guidelines (NSEL 1999)

3.2.2 Geotechnical Investigations and ARD

The bedrock geology of the Black Point area is outlined in Section 6.1.3 of this report and in a Geological Survey of Canada report and accompanying map (Hill 1991). The proposed pit area is underlain by homogeneous biotite-muscovite granite. Analysis of this granite from a suite of samples collected from 10 drill holes distributed throughout the proposed quarry indicated very low concentrations of total sulphur (<0.01%) and these rocks are therefore considered to have non-existent potential for generating Acid Rock Drainage / Metal Leaching (ARD/ML).

In contrast, the processing plant area (the lower platform) is underlain by two rock formations: the Halifax Formation, which forms a wedge-shaped block adjacent to the prominent granite hill where the quarry will be developed, and the Goldenville Formation along the coast from Black Point to Fogarty Head. Since these rocks are known to be potentially acid generating elsewhere in Nova Scotia, the Proponent's geological staff conducted a geological mapping and sampling program in 2011 and submitted a suite of 6 representative samples of bedrock for geochemical and ARD/ML analysis (Dalton 2011). Of the 6 samples collected, only 1 sample contained significant concentrations of sulphide minerals (1.0% total sulphur) and had potential for generating ARD/ML (acid producing potential; $\text{kg/t H}_2\text{SO}_4 = 28.60$), although the pH of this sample was slightly alkaline (7.4 pH) suggesting the presence of carbonate minerals that have pH buffering capacity. The remaining 5 samples from the Halifax and Goldenville Formations had low sulphur concentrations (<0.19%) and have very low potential to generate ARD/ML (acid producing potential; $\text{kg/t H}_2\text{SO}_4 = 0.11 - 0.43$) if exposed during construction.

The site for the processing plant will be developed over Halifax and Goldenville Formation rocks to a mean height above sea level of 22 m. An assessment of the topography at the site indicates that this development will involve both the excavation of a central 11.8 hectare area of Halifax Formation rocks and the in-filling of three separate low-lying areas (1.5, 1.3 and 6.1 hectares; **Figures 3.0-26 & 3.0-27**). The first phase of development for the processing plant area will involve clearing the site of vegetation and grubbing the topsoil to expose bedrock. At that time it will be possible to assess the presence and extent of potential acid generating (PAG) rocks of the Halifax Formation by following the sampling and analysis protocols outlined in the 2009 Mine Environment Neutral Drainage (MEND) Program report entitled *Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials* and the 1995 provincial *Sulphide Bearing*

Material Disposal Regulations. Two representative samples will be collected from each hectare of probable Halifax Formation rocks and these will be submitted for analysis, using procedures in accordance with above regulations and guidelines, to determine if ARD/ML issues are present.

As noted above, the entire processing plant site will be graded and sloped such that all rainfall and drainage will migrate to the south side of the site where it will be collected in ponds. In addition, a 1 m high berm will surround the entire plant site to ensure all surface water is captured. These features will ensure that no acidic drainage will be discharged to Chedabucto Bay.

There are no freshwater streams with fish habitat in the area to be excavated to create the processing plant area, nor are there streams or freshwater fish habitat within 60 m of the site.

If ARD/ML is present, based on the testing of the material from the processing plant site, then this matter will be addressed in accordance with the 1995 *Sulphide Bearing Material Disposal Regulations*, and any appropriate protocols outlined in the 2009 Mine Environment Neutral Drainage (MEND) Program manual for handling sulphide-bearing materials. In addition, long term kinetic testing of PAG or Uncertain PAG material (excavated or disturbed) will be undertaken if needed to evaluate rates of acid generation and neutralization, potential time to onset of acid generation, and drainage chemistry and contaminant loadings in and around the plant site.

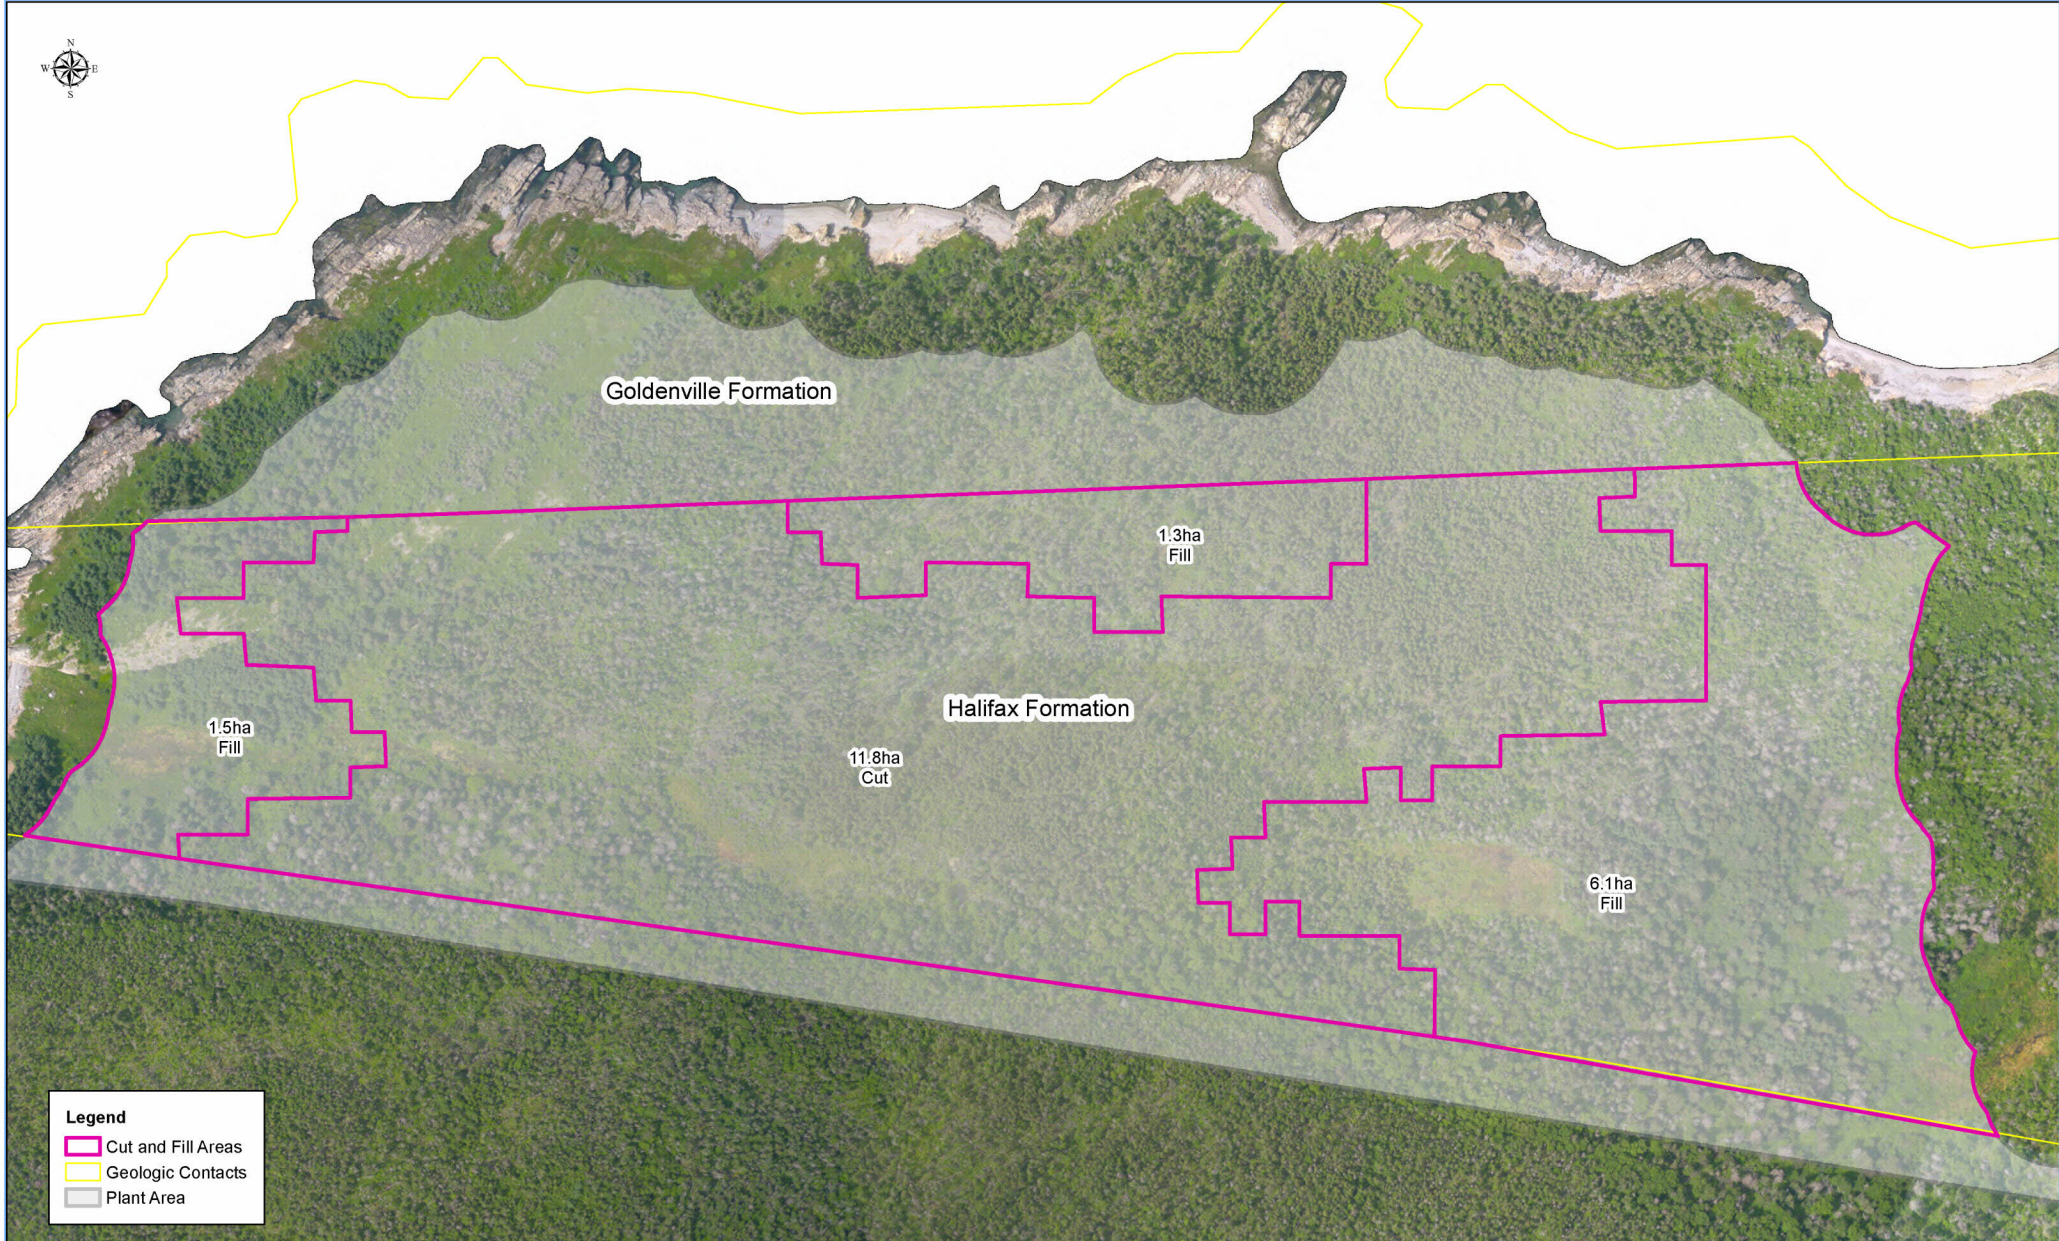

3.2.3 Site Preparation, Cut and Fill, Blasting

The site preparation and construction phase of the Project will begin with clearing of vegetation and removal of organic material and overburden for the development of the 28 ha plant site and administrative area. This area will require cut and fill activities and will be conducted as described in Section 3.2.2.

Preliminary mass balance calculations for the plant and administrative areas suggests a cut or excavation of approximately 600,000 m³ and a fill of 835,000 m³ will be needed to level the area prior to construction (**Figures 3.0-26 and 3.0-27**). The swell factor (i.e., the increase in volume that occurs when solid rock is broken up and excavated) has been estimated at approximately 40%. Additionally, the plant and administrative area will be designed with 1% of cross slope drainage which will direct all storm water to the two ponds described in Sections 3.1.4, and 3.3.7. Any additional required fill material will be generated using the initial mobile processing plant. The final elevation of the plant area and administrative areas will be approximately 22 masl. The site preparation and construction phase of the plant site and administrative area is anticipated to occur over a 36 month period.

As mining activities begin, vegetation and the removal of organic material and overburden will be conducted to establish a rock face at the north end of the property. A phased mining approach will be used to minimize impacts and to allow natural vegetation to remain as long as possible. With the exception of organics, materials extracted during these early development stages will primarily be used for construction of access roads, the laydown areas, and the fill for the marine terminal. Topsoil and excess overburden, if any is encountered, and crusher fines will be stockpiled (separately) and stabilized (e.g., seeded) for future use in the reclamation phase. Much of the overburden will be stored in berms on the edges of the property, thereby increasing sound and visual buffers.

To minimize the potential for erosion and sedimentation, clearing, grubbing and removal of overburden will be conducted in a progressive manner to accommodate drilling and blasting activities, such that the amount of exposed erodible soils is minimized. Clearing activities will take place outside of the breeding season for most bird species (April to September 1) to prevent the disturbance of migratory birds or their nests. If some clearing is necessary during the breeding season, the feasibility of maintaining compliance with the *Migratory Birds Convention Act* will be assessed and a contingency plan developed in consultation with CWS to ensure compliance with *Migratory Birds Convention Act* .during clearing.

3.2.4 Access Road and Transmission Tie-in

Access to the Project site will be made utilizing a new access road that will connect Route 16 to the plant site adjacent to Chedabucto Bay as shown on **Figure 3.0-1**. A majority of the materials necessary for the construction of the road will be extracted from the quarry site. The intersection at Route 16 and a portion of the access road will be paved to minimize dust and track-out issues on Route 16. The intersection will be designed to meet provincial highway department standards.

To the extent possible, the access road will be located so as to avoid watercourse crossings. Where this is not possible, a culvert will be installed. Installation of these structures may require a Water Approval pursuant to the provincial *Activities Designation Regulations* and will be installed between June 1st and September 30th, unless otherwise authorized. Structures will be designed to accommodate the 100 year storm.

Gradients on the access road will not exceed 10%. Similarly constructed gravel access roads within the quarry will be built to connect the land based infrastructure and the ship loading facility. All necessary erosion and sediment controls such as silt fences, temporary sedimentation ponds, and/or rip rap check dams will be installed as required during construction of the road.

During Phases 1 and 2 of the Project, either an electrical service provided by NSPI from the transmission line running adjacent to Route 16 or a diesel powered generator will be required. If necessary, the new service would access the site via the newly constructed access road. All required clearing and grubbing would be completed by the Proponent based upon NSPI requirements. As the sales demand increases, a new service will be required to provide power for the fixed plant. This is expected to be provided by NSPI from the high voltage line running along the southern boundary of the project site. All lines as well as the sub-station are expected to be installed and owned by NSPI.

3.2.5 Processing Plant and Laydown Areas

After the plant site is developed in the early phases of the project and the sales demand has increased to an appropriate level, a large fixed plant will be built. The construction period for the fixed plant will span approximately 18 months dependent upon weather. A majority of the materials necessary for construction will be extracted from the quarry site. This will involve some blasting, heavy excavation equipment, crushing and screening. Depending on the availability of concrete from nearby sources, a small concrete batch plant may be established on-site during the construction period. After site preparation, the activities will shift to installation of foundations.

Prefabrication activities will proceed off site in parallel with civil works, so that as foundations are completed phased delivery of prefabricated structures, equipment skids, subassemblies, and modules can progress. Work associated with electrical and piping needs follow once the structures are erected. Deliveries will be sequenced to support the installation, hook-up, and commissioning program. A majority of the steel structures and equipment will be shipped to the local port and trucked to the site for erection. Several mobile cranes will be utilized on-site during the construction phase.

Construction will be work packaged from the outset so that the integrity of the structures and equipment can be better managed. Construction sequencing will be strongly focused on the testing and commissioning program that brings the plant into operation on schedule. Appropriate dust and drainage control based on the avoidance of environmentally sensitive areas will be applied throughout.

A second construction phase will follow in future years as the sales demand increases. This phase will involve the construction of a second tertiary plant in parallel with the existing one. This work should be completed within approximately six months and will include similar steps as those outlined above with the exception of blasting.

3.2.6 Marine Terminal

The preferred construction approach for the marine terminal employs a fill and rock technique that results in a relatively large footprint on the seabed. A current estimate of the impact totals 11,078 m². Preliminary engineering drawings for the terminal are shown in **Figure 3.0-22 through Figure 3.0-25**. Additional geotechnical work will be required before the drawings are finalized. To accomplish this, a marine engineering firm will be contracted to complete borings of the seabed. This will allow the exact depth, location and integrity of the seabed to be verified.

The terminal will be constructed along the shore using fill and rock (i.e. rip-rap) material sourced from the site. At this time, blasting in the terrestrial near shore area does not appear to be required for construction of the laydown area and approach to the wharf.

The major components of the facility and the expected construction duration of each component are shown below with the total project duration expected to be between 11 and 13 months.

<u>Component</u>	<u>Duration (Sequential)</u>
Caissons	Four Months
Piers/Dolphins	Four to Six Months
Rubble Approach	Two Months
Slewing Rail and Shiploader	One Month

It is expected that slip forming (construction in place) of each caisson will take approximately one week. Installation will be a 24 hour operation until the caisson is cast to about half way between low and high tides. Typical activities include cranes to lift in reinforcing steel, concrete trucks and pumps and lights for night time activity. The completion of each caisson, once sunk, will take approximately one month. The slewing rail piers will be supported by piles which will be installed from a barge. There will be approximately eleven piers which are expected to have four piles each. The piles will be installed using pile driving hammers and churn drills and will be anchored in the bedrock. Silt curtains and acoustic blankets will be considered during installation, as needed. All marine construction will be completed using conventional marine construction techniques.

Prefabricated steel for the slewing rail and the shiploader will be delivered to the site via barge. Installation will be conducted utilizing cranes and work barges. The loadout conveyor (equipped with aggregate spill containment) will extend from the onshore loadout system to the shiploader.

Any piles required for the loadout conveyor in the nearshore area would be located in the rubble fill.

3.2.7 Construction Water Use and Water Management

The construction activities will require water primarily for site dust control. The water will be applied to the areas of the property where earthwork is occurring and to the plant haul roads to control fugitive dust emissions. The portable processing plant will also use water to control dust emissions from the initial crushing operations.

The water volumes used during the construction phase will be minimal compared to the amounts that will be needed when the quarry pit is more fully developed and the permanent processing plant is operational. The water source during construction will be runoff from precipitation captured in retention basins and pit sump. These basins and the sump will be installed early in the construction phase to control sediment runoff and to provide a water supply. In the event that sufficient water is not available at the beginning of construction then water will be procured from off-site sources. Drilled wells will also be considered as an alternative.

Wastewater generated from the construction activities will primarily be runoff from precipitation that falls on the areas disturbed during the construction (i.e., stormwater runoff). Sediment and erosion control measures including site contouring to direct runoff to the retention basins and silt fences, aggregate rock filters, and other best management practices will be employed as needed. These measures will be described in a site-specific Erosion and Sediment Control Plan.

3.2.8 Construction Related Noise

The site development and initial rock processing that will occur during the construction phase will involve activities similar to those that will occur during full facility operation. The equipment used for construction will be similar to the equipment that will be part of the site operation. Noise generated from construction is anticipated to be similar to the noise that will be generated from facility operations. Construction related noise and vibrations will be controlled primarily through attenuation (distance between the source and receptor). The noise levels from the construction activities will comply with the Pit and Quarry Guidelines established for operational sound levels (NSEL 1999). The construction sound levels will be maintained to not exceed the following levels at the boundaries of the Project site:

- 65 dBA 0700 – 1900 hours (Days);
- 60 dBA 1900 – 2300 hours (Evenings); and
- 55 dBA 2300 – 0700 hours (Nights, Sunday and statutory holidays).

Please refer to Sections 6.3 and 7.2 for additional information regarding noise.

3.2.9 Construction Related Traffic

The Black Point Project construction activities will occur within the boundaries of the Project area and will not have a significant effect on public highway traffic. The movement of equipment to the site will occur sporadically during normal working hours. The construction of the site

access road will be done in a manner that minimizes any impact to traffic on the public highway. There will be an increase in vehicles accessing the site during the peak of site construction activity and during worker shift changes. Areas within the facility boundary will be established for parking of construction employee vehicles to prevent any traffic issues associated with parking along the public highway.

Any oversize equipment delivered to the site will be done in compliance with provincial transportation requirements and if necessary protective measures such as flagmen or accompaniment by caution vehicles or police agencies will be followed.

3.2.10 Construction Schedule

A preliminary construction schedule is provided as Table 3-1. It should be noted that the schedule will be dependent on approvals, final designs, and the procurement of equipment. It is anticipated that the construction associated with site development will take approximately 2 years.

As stated previously, the site preparation and construction phase of the project will begin with the clearing of vegetation and removal of organic material and overburden for the development of the plant site. It is anticipated that these initial activities would begin early in the year. To the extent possible, clearing activities will take place outside of the breeding season for most bird species to prevent the disturbance of migratory birds or their nests. Once the site is cleared, the Phase 1 portable plant will be installed and will be utilized to produce crushed stone for rough grading. The total time needed to erect the Phase 1 plant is anticipated to be one week. As outlined in Table 3-1, the Phase 2 portable plant is expected to be added during the second year of operation. It is anticipated that this plant would be added early in the year and will be used to make a smaller diameter crushed stone used to “fine grade” the site. This plant can also be erected in approximately one week. Construction of the marine terminal should start at this time with construction expected to last approximately one year.

Once the site is complete, additional components will be added to the portable plant to produce saleable products. This addition will also have a short construction window due to the portable and modular nature of the components.

As sales demand increases, the Phase 4 plant will be constructed. It is anticipated that construction will start early in the year (Feb/Mar timeframe) with all construction completed by late fall of the same year. The final phase plant will have a construction window identical to the Phase 4 plant.

3.3 OPERATIONS PHASE

3.3.1 Quarry Operation

Please see Table 3-1 for construction to operation schedule. Quarry operations will gradually begin after site construction. Rock processing will generate aggregate and other construction materials for grading the plant area, making concrete for equipment foundations and creating the large stone blocks needed for the marine terminal rubble mound.

Following vegetation removal, drilling and blasting will be employed to loosen the granite in the ground. The blast-generated “shot rock” will be picked up by loaders and excavators and transported by off-road haul truck to the crushing plant (either temporary or permanent). Loading and hauling would occur up to 16 hours a day.

Other quarry equipment includes a rockbreaker (a jack hammer mounted on the end of an excavator), a grader for road maintenance and a water truck fitted with a water sprayer used to suppress dust on the roads and on the muck pile.

Blasting will be handled by a licensed and insured contractor, be performed during the hours of 8 AM to 6 PM, and will not occur on statutory holidays or Sundays. The blasting operator will be responsible for blast designs and methods in accordance with the *Blasting Safety Regulations* made pursuant to the Nova Scotia *Occupational Health and Safety Act*, the Guidelines for the Use of Explosives in or Near Canadian Fisheries Waters (Wright and Hopky 1998), and in accordance with the Nova Scotia Pit and Quarry Guidelines (NSEL 1999).

Blasting is expected to occur 1 to 3 times per month for the first two to three years and increase to 10 to 15 times per month at full operation (up to 120 times per year). Blast locations and depths will be based on pit geometry. The number of drill holes in each blast will vary depending on the purpose and bench geometry. A typical production shot will have less than 100 drill holes each drilled approximately 15 to 17 m deep. Shots utilized for quarry development such as haul roads and sumps will have variable depths generally from 3 to 10 meters. Table 3-2 presents typical blasting parameters. Upon request, residents will be alerted to upcoming production shots via automated telephone notifications ("robo-calls").

Production holes will be in a staggered or square pattern and placed in no more than four rows and will be spaced approximately 3 to 5 meters apart. Typical charge weights per hole will range from 25 kg during construction to 400 kg during normal operations. The explosive charge will consist of ammonium nitrate and fuel oil (ANFO) and an appropriate concentration of waterproof emulsion. All blasting will be conducted by a third party vendor who is licensed and insured. Blasting materials will not be manufactured or stored on site.

Benches will generally be 15 meters in height, although during the initial development phases, face heights could be less. Safety benches will be established every two benches and will have a width of approximately 7.5 meters. The final slopes for the quarry will have face angles of 85 degrees with a maximum pit slope of 65 degrees. Working benches will have face angles of 70 to 75 degrees.

Haul roads within the pit will be constructed for the movement of personnel, equipment, and materials within the quarry. Haul roads will be 30 m wide and will have a maximum grade of 10%. Sump ramps will be 20 m wide with a maximum grade of 15%.

**Table 3.1:
Construction to Operation Schedule**

Activity	Anticipated Commencement	Anticipated Completion
EA Approval	Q4 2014	Q4 2015
Mining		
Establish Access Road	2018	2018
Site Preparation	2018	2020
Establish Haul Road to Plant	2020	2020

Shot Patterns	Staggered or Square	Staggered or Square	Staggered or Square	
Distance to nearest non- company structure	>925	>925	>2,260	m
Distance to water	>250	>150	>75	m

Legend

Definitions:

Burden: The distance from the borehole and the nearest free face or the distances between the boreholes measured perpendicular to the spacing

Spacing: The distance between boreholes. In bench blasting, the distance is measured parallel to the free face and perpendicular to the burden.

3.3.2 Processing Plant Operation

The type of processing plants at Black Point will vary from a small portable plant to a large fixed plant but the operations for each will be similar. Since the larger plant has a potentially greater impact, it is discussed in this section.

Blasted rock will be loaded by front-end loaders or hydraulic shovels into appropriately sized haul trucks to transport the blasted rock to the primary crusher located within or just outside the quarry boundary. This material will be dumped into the primary dump hopper where it will be fed into the primary crusher(s).

After being reduced in size at the primary crusher, the rock will be transported via conveyor to a primary surge pile located near the secondary circuit of the plant. Material will then be reclaimed (transported) from the surge pile utilizing a tunnel and conveyor and sent to the scalping screen and secondary crusher where it will be further sized and reduced. A base material (-1 ½") will be removed from the scalping screen and stockpiled by conveyor. The discharge of the screen and secondary crusher will be conveyed to a secondary surge pile.

The material in the secondary surge pile will be reclaimed by conveyor and fed into the tertiary portion of the plant. This material is routed through the remainder of the crushing and screening plant via conveyors to produce stockpiles of graded material. All stockpiles will be located over blending reclaim tunnels.

Material can be fed directly from the blending tunnels to the rinse screen(s) or a bypass conveyor around the screen(s) in various proportions to meet individual product specifications. This product will be stockpiled over tunnels that will feed the ship loadout system. The slurry generated on the rinse screen(s) will be piped to the sand screws with the overflow pumped to a clarifier and fines recovery system. The water will be reclaimed for future use.

Processing aggregate will require the operation of a variety of equipment including primary crushers (jaw or gyratory), surge piles, screens, cone crushers, reclaim tunnels, conveyors, waterlines and pumps, water clarification tank, generators and other associated mining equipment. This plant will be operated by electricity, but the portable plant may be powered by generators. Mobile equipment will likely include excavators, loaders, off-road trucks, bulldozers, water trucks, cranes, drill rigs, service vehicles, work boat, rock breaker, and barge.

Conveyors will be inter-locked and equipped with motion sensors that will stop the conveyance of material should there be an overload situation, thus preventing spillage. Routine inspection and maintenance will be conducted on all equipment.

3.3.3 Operational Water Requirements

The operational water requirements for the processing plant will vary from approximately 8.8 L/s in Phase 1 to approximately 44.7 L/s in Phase 5. During the first two phases of the project as outlined in Section 3.1.3, the only water needs will be for dust suppression, base material moisture addition and potable water. It is expected that surface water accumulating in one of the two the settling ponds will satisfy the dust suppression and base moisture addition needs. Potable water needs will be met either through the purchase of water from off-site sources or by drilling a well.

During Phase 3 of the project, additional modules will be added to the portable plant to produce saleable aggregate products. One of the modules added will be a wash plant. The wash water system will be operated as a closed loop system which recycles as much of the water as possible. This plant will have two ponds: one will collect surface water for use at the processing plant and for dust control while the other will be kept dry and used to manage and treat stormwater collected on the lower platform. Each of the two ponds is designed to allow fine sediment to settle out over their length so that the water can be reused, or if excess volume is present, discharged to the ocean. A long-armed backhoe will be utilized to remove accumulated sediment from the ponds.

In the last two phases of the project a large fixed plant will be installed. The plant will continue to have a wash water system that will be operated as a closed loop system. The slurry discharge from the wash screen(s) will be piped to a sand screw(s) to recapture the coarse fines. The overflow from the sand screw(s) will be collected and pumped to a fines collection system that will have a clarification system as well as a system to extract fines. Clean water will be returned to the pond for reuse. The fixed plant will also have other needs for this clean water such as wash down stations and sprinkler heads for area dust suppression. An instantaneous water demand of approximately 708 gallons per minute (44.7 L/s) is estimated at peak production with a majority of the water recovered from the site.

3.3.4 Offloading to Ships

The shiploader will load aggregate into the holds of ships (up to 70,000 tonnes) and possibly barges that will transport the material to the end markets. Aggregate loading onto the ships will approach 5,000 TPH once the full load-out system is completed. It is estimated that it will take approximately 18 to 24 hours to load the largest ships and that approximately 90-100 ships will be loaded per year once the plant reaches peak production.

Aggregate products will be the only material loaded at the Project site.

3.3.5 Liquid Fuel Delivery and Storage

The Black Point operation will use diesel fuel in mobile equipment throughout the life of the facility, and to power on-site generators and portable plant equipment that will be used in the initial phase of the operation. The operation will also use other liquid petroleum and non-petroleum (antifreeze) products for equipment maintenance.

The delivery of these materials to the site will be by truck from the material suppliers who routinely handle these materials. The transfer of these materials into storage tanks at the facility will be attended by the delivery driver so that any equipment or other issues that could result in a spill are identified promptly and corrected before a spill incident occurs. The diesel fuel and other liquid petroleum products will be stored on-site in above ground storage containers in proximity to the shop. At this time, it is expected that fuel storage requirements will be met with one to two diesel storage tanks each sized at 20,000 gallons (75,708 L) or less, and one 5,000 gallon (18,297 L) gasoline reservoir. Various lube oils and other maintenance related fluids will be stored in 55 gallons (205 L) or smaller drums and a series of 4 to 8 tanks with capacity of less than 1,000 gallons (3,885 L) each.

All storage tanks will be either double walled self-contained tanks or single walled tanks with secondary containment. All petroleum storage containers 205 L (55 gallons) or larger will be stored within a contained area. These materials will be stored and handled in accordance with

all relevant regulations. The fuelling area will be erected on a reinforced concrete slab or lined containment area enclosed within side curbs and with a sloping floor to contain any spills and/or leaks that may occur during fuelling.

3.3.6 Hazardous Materials Management

The hazardous materials associated with the facility will include blasting agents, waste petroleum products, and waste materials including batteries, spent parts washer fluids, used oil and anti-freeze. No pesticides or herbicides will be used on site. All of the materials stored on site will be managed to prevent spills or other releases that could impact the environment or contaminate surface water runoff. The materials will be stored in tanks and or containers in dedicated, contained areas to prevent any spills from reaching the outside environment. Hazardous materials will be handled and stored in accordance with provincial hazardous materials regulations and will be transported for off-site disposal using a licensed hazardous waste transport company. Employees will be trained on proper handling and management practices for these materials.

3.3.7 Wastewater Management

Septic Wastewater

The Project will generate sewage and greywater waste, which will require treatment either on site using a standard wastewater treatment system, or offsite at a municipal wastewater treatment facility. It is expected that during the construction and early operations phases of the project, portable sanitation units will be utilized. A permanent washroom and bathing facility may be constructed at a later date as the project advances through the operations phase.

The Project site will not have a conventional septic tank and soil absorption disposal field due to the shallow soil overlying the bedrock, which will not permit adequate treatment of the wastewater. As an alternative, it is anticipated that a large volume holding tank will be utilized during the construction phase of the project. The sewage and greywater waste would be directed to the holding tank and pumped out by truck to be hauled by a licensed septic waste transport company for offsite treatment. It is anticipated that holding tanks totalling 227 m³ will be sufficient to collect the waste from 60 workers for two weeks, after which the tanks would be emptied and the waste transported for offsite treatment (NLDEC 2005). This volume provides for 1.5 times the maximum daily flow for two weeks³.

A conventional raised bed septic system (where the treatment medium, typically sand, is imported onto the site) will also be considered as a possible alternative on-site treatment method. The type of raised bed system suitable for the project site would be determined at a later date following the completion of test pits that would provide technical information about the soil profile at the proposed system location. In both cases, the magnitude of waste generated will be proportional to the number of workers employed at the project site. The volume of the holding tank or size of the raised bed septic system will be based on peak employment estimates.

The treatment methods, design, construction, maintenance and management of the on-site system will take into account the regulations, guidelines, policies, and standards that have been established by the Nova Scotia Department of Environment, including Technical Guidelines for

³ 60 persons x 180 L/person/day = 10,800 L x 14 days = 151,200 L (151 m³ + security factor = 227 m³)

On-Site Sewage Disposal Systems and other guidance documents (NSE 1997; NSE 2006; NSE 2007; NSE 2013).

The location of the wastewater treatment system would likely be adjacent to the office and maintenance shops shown on **Figure 3.0-20**.

Stormwater and Wash Water

Stormwater at the Black Point operation will include surface water runoff from precipitation (including snowmelt) falling on the processing and quarry areas. Within the pit, this will also include minimal groundwater inflows described in the Hydrogeological Technical Study (**Appendix A**). Wash water will consist of collected stormwater and will be used in the granite washing process to remove fines from the granite in the processing plant. This water will be collected and reused.

Stormwater and wash water from the processing area (the lower platform) will be managed by sloping the processing area so that water is directed away from the Chedabucto Bay to one of two settling ponds located along the base of the cliff at the southern edge of the lower platform. The two 6,100 m³ settling ponds are sized to provide sufficient retention time for any suspended solids (rock fines) to settle out leaving clarified water. Stormwater retention ponds are sized to comply with NSE 1988 Erosion and Sedimentation Control Handbook guidelines, which equates to 11 days residence time for mean annual runoff through the ponds (please see the Surface Water Technical Report, **Appendix C**). The clarified water will be reused for product washing and site dust control, or tested and discharged if needed. Any excess untreated water can be pumped to the pit sump described below. Should a power failure occur, the settling ponds can be allowed to overflow, since the water will simply accumulate around the ponds rather than flow to Chedabucto Bay. This will allow containment and eventual treatment of the entire storm event.

In the quarry stormwater will be routed by sloping and shallow drainage ditches to the quarry floor for collection in the pit sump. The pit sump consists of a large excavated basin designed to retain water for reuse. Initially, the pit sump will measure approximately 45 x 60 m with a depth of 4.5 m and a volume of 12,000 m³. The sump can be expanded proportionally as the quarry expands through Phase 3 (64,000 m³), and Phase 5 (386,000 m³). As is the case with the retention ponds in the processing area, the pit sump can overflow with no negative effect on operations. In the event of overflow, water would be allowed to clarify in place prior to testing and discharge to the ocean, or would be pumped to the settling ponds for clarification.

The Project is designed to allow pumping of water from the settling ponds to the quarry sump and vice versa in a closed loop recycling process to ensure sufficient wash water is present at all times. The combination of retention ponds, quarry sump and land sloping is adequate to contain a 100-year 24 hour storm event.

The water management system will be designed to provide capability for non-routine discharges of clean water from the quarry sump. Any discharge to the ocean will be required as a minimum to meet water quality standards listed in the Pit and Quarry Guidelines (NSEL 1999) as well as quality criteria stipulated in the operating permits and authorisations. These criteria will include for example total dissolved solids, pH, oil and grease, nitrates and other constituents required by the permitting agencies. The final location of the discharge point will be established during the detailed design phase but is anticipated to be in the southwest zone of the lower platform nearest to the settling ponds. The quality of any discharged water is expected to be equivalent

to or better than the highly acidic surface discharges currently received from Fogherty Lake and Murphys Lake.

3.3.8 Other Waste

The project will generate various types of waste and recyclable materials as a result of construction activity, and routine operation of the facility. The materials that will be generated include:

- Non saleable crushed granite, termed product fines, granite fines or crusher fines (crusher fines is the term used in this EIS).
- Typical “curbside” solid waste. This will include paper, plastic, cardboard, food scraps, aluminum cans, glass bottles and containers, and other trash. Much of this material will be collected in dedicated containers for recycling. Small volumes of medical waste may also be generated on occasion.
- Vehicle and equipment maintenance waste. Routine maintenance activities will generate a variety of waste materials including used antifreeze, used oil and hydraulic fluids, paint, used oil and fuel filters, spent batteries, tires, conveyor belting, miscellaneous equipment parts, scrap steel, wood pallets, light bulbs, petroleum contaminated rags and other petroleum contaminated media (pads, soil, granite fines, rags).

The Proponent’s approach to waste management is to use pollution prevention techniques to minimize the amount and types of waste materials. This also reduces the amount of material shipped off-site for disposal which reduces the risk of liability associated with the off-site disposal site. All wastes will be sorted and transported to a licensed recycling facility using authorized local services in compliance with the Nova Scotia Solid-Waste Resource Management Regulations and municipal requirements. Materials that cannot be recycled will be managed using authorized landfills for disposal. All waste materials and materials awaiting shipment or pick-up will be properly stored to prevent accidental release of substances to the environment.

3.3.9 Operation Related Noise and Light

The Black Point operation will generate noise from the operation of mobile equipment, the processing plant, blasting and product loadout at the marine terminal (please see Section 6.3 for more information on anticipated noise levels).

The facility will employ a number of noise mitigation measures consistent with guidance presented in resource materials provided to the Proponent by Health Canada. These measures will both reduce noise at the source and reduce noise emanating from the facility through attenuation by design. Together, these measures will reduce noise levels outside the property boundaries. Noise reduction and mitigation measures will include:

- specification of reduced noise equipment, especially mobile equipment;
- procurement of equipment that meets US EPA Category IV air emission standards for off-road diesel equipment which tend to generate less noise than older equipment;
- confinement of most mobile equipment within the quarry pit below ground surface so the pit walls will attenuate noise levels;
- retention of natural barriers such as hillsides to the extent possible;

- placing product stockpiles and other structures to attenuate the noise from the processing equipment;
- consideration of alternative back-up alarms systems for mobile equipment;
- enclosure of the majority of the screening towers to reduce noise transmission;
- restricting operating hours for the quarry and processing plants to 16-hours per day so that noise levels are reduced during night time; and
- restricting blasting to daytime hours and weekdays.

In addition, the Proponent will periodically measure noise levels of the equipment and operation using portable dosimeters and track the levels so that increasing noise levels that could indicate equipment issues can be identified and corrective action taken. The Proponent also conducts employee noise exposure monitoring as part of the Safety and Health program. The employee noise monitoring will identify issues with work place exposure to noise that will target the source of the noise internally to minimize the risk of a noise issue outside of the facility property. The Proponent will also maintain an open communication with the community and the neighbours in the Black Point vicinity to identify any concerns with noise levels so that the issue can be addressed. All of these measures, combined with the distance of the site operations from off-site noise receptors (homes), will ensure that the site complies with the Pit and Quarry Guidelines established for operational sound levels (NSEL 1999). These Guidelines stipulate that noise levels are not to exceed the following levels at the boundaries of the Project site:

- 65 dBA 0700 – 1900 hours (Days);
- 60 dBA 1900 – 2300 hours (Evenings); and
- 55 dBA 2300 – 0700 hours (Nights, Sunday and statutory holidays).

A comprehensive noise assessment has been prepared for the facility that included measurement of background noise levels at the site and in proximity to the nearby noise receptors, and estimation and modelling of projected noise impacts associated with the operation. The results of this assessment are provided in Section 6.3.

Operational impacts on human-perceived night time light levels are anticipated to be limited. This is because the site layout and natural terrain restrict direct line-of-site visibility of the operation from the east and west. The distance of the operation from the nearest residents, combined with 30 m wide forested coastal buffers (and undeveloped Black Point itself) will help minimize any impacts. The quarry will not be visible from Route 16 due to the distance, vertical change in topography, and forested slopes.

Light will be generated from vehicles using onsite access roads and parking lots, exterior lighting, and lighting of the marine terminal. Illumination will be minimized by shielding lights to shine only where needed to ensure the safety of employees. The facility lighting will also be designed to minimize impacts by controlling the intensity of the lighting sources used and by careful placement of light sources. To the extent possible lights will be located where structures, buildings and natural barriers block transmission in the direction where neighbours are present. Lighting will be reduced to a minimum level in non-operational areas during night time hours. Any maintenance activity will take into consideration light impacts and adjust to provide the light needed to safely perform the task while trying to minimize off-site impacts. Please see Sections 6.3 and 7.3 for additional detail regarding anticipated light emissions.

3.3.10 Air Emissions

Dust emissions during all phases of the Project will be controlled with the application of water obtained from the settling ponds and water that has pooled on the quarry floor and collected in the quarry sump. Biodegradable products proven to significantly minimize fugitive dust may also be used following approval from NSE. To minimize dust emissions associated with truck traffic, conveyors will be used to transport rock from the pit to the laydown area. Processing equipment will be designed to minimize drop heights at transfer points and certain equipment will be fitted with water spray nozzles for dust control.

Combustion emissions will be generated from all phases of the Project as a result of fuel combustion in Project equipment and vehicles. Specific emissions associated with the Project include: sulphur dioxide (SO₂), nitrogen oxides (NO_x), volatile organic compounds (VOCs), carbon monoxide (CO), carbon dioxide (CO₂), and trace products of particulate matter (PM). These combustion related emissions will be minimized through the use of mobile equipment and electrical generators that meet US and Canadian Category IV emissions standards. These emissions are also minimized through the use of ultra low sulphur fuel in on-site mobile and fixed equipment. The use of conveyors will reduce trucking emissions; regular equipment maintenance and reduction of idling time will also ensure emissions are reduced.

The air quality impacts of the estimated emissions of dust particles and combustion related compounds were determined through the use of air quality dispersion modelling (Section 7.1 Air Quality and Climate Change and **Appendix O**). The modelling results were compared to federal and provincial air quality standards to assess potential Project-related impacts. The air quality assessment demonstrates that the Project emissions will not exceed applicable ambient air quality standards at any locations where off-site receptors (residences) are present.

Visible emissions monitoring will be conducted following installation and the start of operation of each crusher, screen, conveyor, and other pieces of processing equipment that is not wet. Compliance with applicable opacity standards will be confirmed and if found to be non-compliant, improvements in dust control will be implemented to achieve compliance before the equipment is returned to full operation. Daily visual observations of the operational areas including the processing plant and loadout areas, haul roads and stockpiles will be performed by site management personnel and any areas with visible dust will receive additional water applications, adjustments dust control equipment to improve effectiveness, or if the issue cannot be immediately corrected, by shutting down the equipment or area until corrective measures can be taken. The Proponent will apply adaptive management techniques and use the monitoring results to guide decision-making on an ongoing basis throughout each operating day.

The estimated annual emissions for each of the five operational phases are provided in Table 3.3. These values are maximums for peak production amounts anticipated in each phase.

Table 3.3:
Total Criteria Pollutant Emissions from Quarry and Processing Plant (tonnes/year)

Project Phase	Total Suspended Particulate (TSP)	Particulate Matter <10 microns (PM10)	Particulate Matter <2.5 micros (PM2.5)	Nitrogen Dioxide (NO2)	Carbon Monoxide (CO)	Volatile Organic Compounds (VOCs)	Sulfur Dioxide (SO2)
Phase 1	6.16	1.83	0.76	30.64	24.99	3.39	1.48
Phase 2	22.78	6.31	2.70	54.12	36.15	6.12	1.60
Phase 3	47.09	14.58	2.92	77.50	62.48	8.33	2.00
Phase 4	99.84	33.42	6.19	91.76	92.15	9.87	2.00
Phase 5	114.56	37.44	7.28	105.35	109.07	11.08	2.80

(source: Vulcan Materials Company)

Greenhouse Gas Emissions

The Black Point quarry, processing plant and loadout operations will result in the direct emissions of greenhouse gases, primarily carbon dioxide (CO₂) and to a lesser extent methane (CH₄) and nitrous oxide (N₂O). These gases are combustion by-products from fuels used in mobile equipment and the diesel powered engines associated with the portable processing plant in operational Phase 1 through Phase 3. A small amount of greenhouse gases are also generated on a discontinuous basis from blasting within the quarry pit. The estimated amount of greenhouse gases generated as direct emissions by the land based operations (excluding marine terminal) are 4,793 annual tonnes of carbon dioxide equivalent (CO₂e) emissions during Phase 1. GHGs from the marine terminal are described later in this section.

The levels of greenhouse gas emissions increase proportionally as production increases, to a maximum estimated emission level (land based only) of 8,522 tonnes of CO₂e annually during Phase 5. The estimated amounts of direct greenhouse gas emissions by operating phase are presented in Table 3.4.

Table 3.4:
Tier I - Direct GHG Emissions Quarry, Processing Plant and Loadout

Project Phase	CO2 (tonnes/yr)	CH4 (tonnes/yr)	N2O (tonnes/yr)	CO2e (tonnes/yr)
Phase 1	4,708.00	5.40	79.90	4,793.30
Phase 2	7,195.00	8.20	122.20	7,325.40
Phase 3	6,421.00	7.30	109.00	6,537.30
Phase 4	8,330.00	9.50	141.50	8,481.00
Phase 5	8,371.00	9.60	142.00	8,522.60

(source: Vulcan Materials Company)

The Black Point project will require approximately 9,000 kilowatts of electrical power primarily for the operation of the processing plant equipment in Phases 4 and 5. This amount of electricity generation by the electric utility will result in an indirect greenhouse gas emission rate of 1,058 tonnes of CO₂e per year during peak production in Phase V. Lesser amounts of electricity will be needed in earlier phases. The indirect emissions due to electricity utilization are resented in Table 3.5.

Table 3.5:
Tier II - Indirect GHG Emissions for Electric Power Usage

Project Phase	Maximum Electricity Demand (Horsepower)	CO2 (tonnes/yr)	CH4 (tonnes/yr)	N2O (tonnes/yr)	CO2e (tonnes/yr)
Phase I	180	15.78	0.02	0.06	15.86
Phase 2	180	15.78	0.02	0.06	15.86
Phase 3	180	15.78	0.02	0.06	15.86
Phase 4	12000	1,052.09	1.05	4.31	1,057.46
Phase 5	12000	1,052.09	1.05	4.31	1,057.46

(source: Vulcan Materials Company)

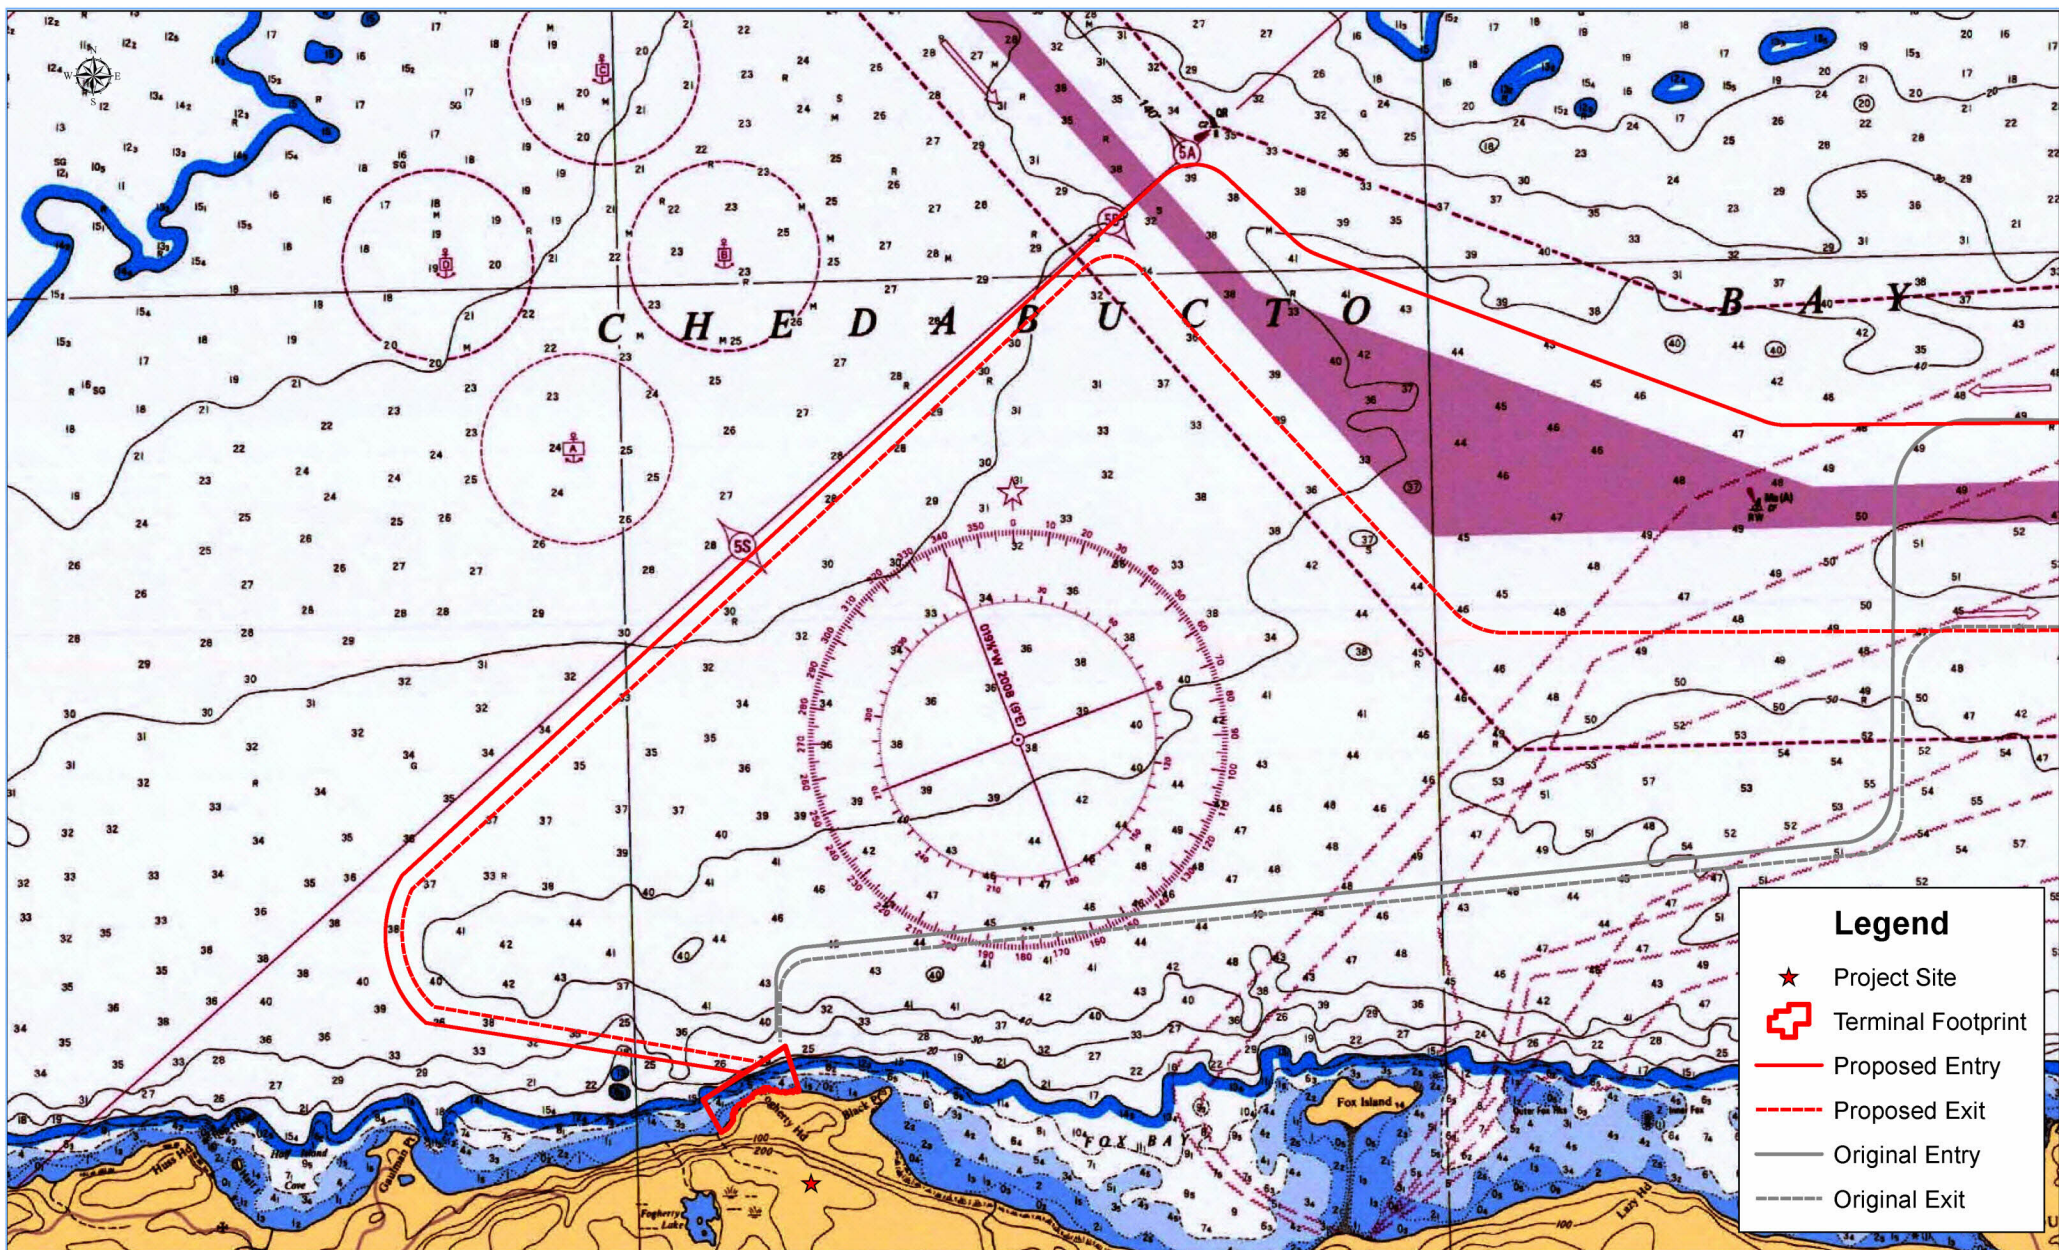

3.3.11 Marine Vessel Operations

The typical vessel used to transport aggregate is a 70,000 DWT “Panamax” size ship (**Figure 3.0-28**). During the initial stages of production before the plant is operating at maximum capacity, ships will arrive at the terminal on average approximately 1 to 3 times per month. As market conditions warrant, this will increase to a maximum of 1 to 2 ships per week. Ship loading typically requires 18 to 24 hours and so a typical cycle of arrival–berthing-loading-departure requires on average one to two days. Aggregate products will be the only material off-loaded at the Project site. Shipping will typically be arranged through the customers, who will arrange for ship arrival and departure at the marine terminal.

Operating limits for the marine terminal will be established during the final marine terminal design stage. The Environmental Management Plan will define the operating limits for the vessel to remain alongside the terminal will be developed. The Plan will identify and establish limits for severe atmospheric and/or oceanographic conditions for all marine terminal activities including berthing, mooring, and aggregate loading. The vessel will vacate the berth if and when these limits are reached.

Figure 3.0-28:
“Panamax” Size Ship

The proposed shipping route is for discussion purposes.
The actual shipping route is subject to ongoing transportation studies and government approval.

PLOTTED: LAST UPDATE: 0 500 1,000 2,000 3,000 Meters

DATE	REVISION	BY	ISSUE DATE:

THIS DRAWING AND ORIGINAL DETAILS ARE THE PROPERTY OF VULCAN MATERIALS COMPANY AND MUST BE RETURNED UPON DEMAND. THIS DRAWING MUST NOT BE COPIED, REPRODUCED, OR USED WITHOUT PERMISSION.

Proposed Shipping Routes

REGION	NOVA SCOTIA	PLANT	BLACK POINT
DATE	08/23/2014	DWG. NO.	Figure 3.0-29
SCALE	1 in = 1,000 m		

A proposed shipping route from the inbound shipping lane to the marine terminal is shown on **Figure 3.0-29**. Two routes have been examined and after consultation with local fishermen, a preferred route was selected. It should be noted that the route used on any given voyage will depend on weather, traffic, safety, local pilot instructions and other factors. Due to the large size of vessels, speeds within Chedabucto Bay during the approach to the terminal are anticipated to be less than 2 knots. Elsewhere with the Bay, vessel speed would be at the Master's discretion under the pilot's advice. Outside of Chedabucto Bay, ships will generally travel at a speed of 14 knots.

If severe weather is forecast, the ship captain in consultation with the local pilot assigned to the vessel will determine the appropriate course of action. Ship crews will be fully trained of their responsibilities in the event of a weather-induced emergency at sea, and proper emergency response and escape equipment will be onboard at all times. If an instance of severe weather develops, the marine terminal may be used as a refuge for fishing boats or ships in the immediate area.

Ships are to adhere to all relevant laws, regulations and permits to ensure environmental compliance, and meet all regulatory standards pursuant to the *Canada Shipping Act*, including, but not limited to the:

- *Ballast Water Control and Management Regulations;*
- *Navigation Safety Regulations; and*
- *Ship Station (Radio) Regulations.*

It should be noted that no fuel tanker vessel traffic will occur as a part of the Project. There will be no bulk fuel or oil transport or transfer to or from ships while at the marine terminal and bilge water and deck wash discharge at the terminal will only occur in compliance with the federal government's *Ballast Water Control and Management Regulations*. Additional detail on bilge and ballast water management is provided in Section 6.11 Shipping and Navigation.

3.3.12 Emissions to Atmosphere from Marine Operations

The Project will result in air emissions of dust (particulates) and fuel combustion byproducts emitted by ships during transport and loading operations. The combustion related emissions will include: sulphur dioxide (SO₂), nitrogen oxides (NO_x), volatile organic compounds (VOCs), carbon monoxide (CO), carbon dioxide (CO₂), and trace products of particulate matter (PM).

Estimates of direct GHG emissions associated with ship operations and product transfer are presented in Table 3.6. The emissions estimates were prepared using factors provided in "Environment Canada GHG Emission Quantification Guidance for Fuel Combustion" using the mobile equipment guidance for light oil fuelled ships⁴. The fuel consumption values used in to prepare the estimates were 4.6 tons per day docked and 37.1 tons per day in transit.

⁴ <http://www.ec.gc.ca/ges-ghg/default.asp?lang=En&n=AC2B7641-1#section5>

The GHG emissions associated with the berthing of the ship during loading at the marine terminal and the emissions associated with manoeuvring within the Project operating area are presented in Table 3.6.

Table 3.6:
Tier I - Direct GHG Emissions from Vessel Operations at Marine Terminal

Project Phase	CO2 (tonnes/yr)	CH4 (tonnes/yr)	N2O (tonnes/yr)	CO2e (tonnes/yr)
Phase 1	201.37	0.40	0.00	201.77
Phase 2	279.67	0.56	0.00	280.24
Phase 3	425.11	0.85	0.01	425.96
Phase 4	626.47	1.25	0.01	627.73
Phase 5	939.71	1.87	0.02	941.59

(source: Vulcan Materials Company)

The greenhouse gas emissions for roundtrip vessel travel between the Black Point project boundary and the edge of Canadian economic zone waters are provided in Table 3.7. This information is based on an estimated vessel travel distance of 500 km round trip which will vary based on the specific route each vessel navigates.

Table 3.7:
Emissions for Total Annual Vessel Haulage (To/From Canadian Economic Zone Edge)

Project Phase	CO2 (tonnes/yr)	CH4 (tonnes/yr)	N2O (tonnes/yr)	CO2e (tonnes/yr)
Phase 1	3,240.00	0.58	2.42	3,243.01
Phase 2	4,500.00	0.81	3.36	4,504.17
Phase 3	6,840.00	1.23	5.11	6,846.35
Phase 4	10,080.00	1.82	7.53	10,089.35
Phase 5	15,120.00	2.73	11.30	15,134.03

The Canadian National GHG Inventory for the 2012 calendar year shows the carbon dioxide equivalent emission levels for Nova Scotia to be 17,400 kt with 11,700 of that amount from stationary combustion sources and 5,530 for transport emission sources. The mining and oil and gas industrial category generated 201 kt of emissions.

Unlike priority pollutant air contaminants such as NO_x and CO there are no ambient air quality standards for greenhouse gases. In addition, the impact of greenhouse gas emissions on the environment is cumulative in nature and is supplemented by natural processes such as volcanic eruptions. The impact of the Project's greenhouse gas emissions can be evaluated through a

comparison of the Project emission levels to both the levels of emissions in Nova Scotia in general and to the emission levels of similar industries.

The Project's total GHG emission level at the maximum generation rate during Phase 5 is estimated at 9,464 tonnes per year CO₂e. This level is roughly 0.05% of the Province's total GHG emissions for 2012 of 17,400,000. The Project GHG emission level is also roughly 4.7% of the 2012 reported emissions of the mining and oil and gas industrial category. The Project represents 0.0000283 percent of the 2012 World Wide emissions for the fuel combustion and cement production source categories.

The Project's greenhouse gas emissions will not contribute significantly to these emissions levels. The Proponent will minimize GHG emissions by purchasing heavy off-road mining equipment that meet the US EPA and Canadian Tier 4 engine standards, operating mobile equipment with fuel efficiency in mind by eliminating unnecessary idling and shutting off equipment when it is parked (unless there is a safety or maintenance reason it is running), utilizing conveyors in the process to reduce the need for mobile equipment, and through the use of ocean vessels to ship the product reducing more energy intensive ground transportation options. This last point is illustrated in Table 3.8. This table summarizes the GHG savings of shipment achieved through the use of ocean vessels versus rail and truck. The GHG emission savings are dramatic ranging from 19% to 89% per vessel shipment.

Table 3.8:
Vessel Operation GHG Analysis

CO ₂ e Emissions Vessel Travel to Delivery Point (tonnes/trip)				GHG Emissions CO ₂ e	
North Caroline to Virginia Area	Charleston, SC	Miami, FL	Tampa, FL	Total By Phase	
611	683.00	1,013.00	1,283.00	Phase I	16,155.00
Alternatives Analysis				Phase II	22,437.50
Land Shipment from Vulcan Quarry to Same Market Area				Phase III	34,105.00
GHG CO₂e Per Equivalent Single Vessel Shipment				Phase IV	50,260.00
752	1,505.00	8,986.00	5,354.00	Phase V	75,390.00
% GHG Reduction by Ocean Vessel Shipping (per ship trip)				Phase V Annual CO ₂ e Savings (tonnes)	
18.8%	54.6%	88.7%	76.0%	273,147

3.4 DECOMMISSIONING PHASE

3.4.1 *Transfer of Ownership and Control*

The Proponent will lease the property from the MODG for the life of the quarry, estimated to be sometime after 2070. The land will be returned to the MODG following the completion of operations, equipment decommissioning, removal of plant and marine terminal infrastructure, and the acceptance of site decommissioning and reclamation activities.

A description of the site following operations and decommissioning activities and details of a conceptual rehabilitation plan are provided in the following sections.

3.4.2 Rehabilitation Plan

In accordance with the requirements of the provincial Pit and Quarry Guidelines (NSEL 1999), the Proponent will prepare a written plan approved by NSE to provide for partial or total abandonment and rehabilitation of the site. It is anticipated that the plan will include an initial rehabilitation plan, progressive rehabilitation measures and / or a final rehabilitation plan. The Proponent will also post interim and final security bonds for the quarry, as required by the Pit and Quarry Guidelines and the *Approval and Notification Procedure Regulations*.

The rehabilitation plan will be developed for the Project site and submitted to regulators for review as part of the provincial Part V Industrial Approval application. The plan will include short-term and long-term reclamation efforts as well as details of the proposed final reclamation plan such as topography, maximum slopes, re-vegetation plans, and potential future land uses once the quarry operation is complete.

All areas of the Project site affected by quarry activities including the plant site and settling ponds, marine terminal, access roads and the quarry floor will be included in the rehabilitation program. The final reclamation plan will be developed in consultation with various stakeholders such as provincial and municipal officials, non-government organizations and conservation groups, adjacent landowners, and Mi'kmaq representatives. A draft Table of Contents is given below.

Rehabilitation Plan Draft Table of Contents

- 1.0 Introduction
- 2.0 Baseline Information
- 3.0 Project Facilities and Areas
 - 3.1. Open Pit
 - 3.2. Processing Plant
 - 3.3. Marine Terminal
 - 3.4. Infrastructure
 - 3.5. Water Supply, Treatment, and Discharge
- 4.0 Conceptual Decommissioning and Reclamation Plan
 - 4.1. Site at Closure
 - 4.2 General Strategies
 - 4.2.1 End Use Objectives
 - 4.2.2 Goals
 - 4.2.3 Plan for Managing Surficial Materials
 - 4.2.4 Plan for Managing Re-Vegetation
 - 4.2.5 Plan for Water Management

6.1.	Site Maintenance
6.2.	Reclamation and Vegetation Monitoring
6.3.	Water Quality Monitoring
7.0	Schedule
8.0	Costs
9.0	References.

3.4.3 Site Description at Closure

The site will include the following elements at the end of operations (**Figure 3.0-30**):

- An open pit that will be flooded to create an aquatic feature with viable habitat,
- Permanent submersion of the solid granite quarry floor and associated haul roads,
- A graded area including the plant site and material storage areas,
- Engineered ponds and sumps that supplied water to the processing plant,
- Minor disturbed areas immediately adjacent to the open pit,
- Appropriate surface water drainage structures (ditches, swales) in and around the Project site, and
- Site buildings and road(s) needed for care and maintenance of the site after operations end.

3.4.4 Reclamation Objectives

The reclamation objective is to restore aquatic and terrestrial habitats to the extent possible so that indigenous flora and fauna can occupy or exploit areas recently used to support quarrying operations. The overall end use objective is to promote land uses and habitat types within the Project area that are similar to those that occurred before the Project was initiated. Other recreational or commercial land use opportunities may develop during the life span of the quarry and will be examined in coordination with the MODG and other stakeholders.

At closure, all unneeded buildings and equipment will be decommissioned and removed from the site. The water management system used during operations will be re-configured to ensure

stable site drainage and water quality that meets applicable standards for discharge. The landforms that remain after operations will be reclaimed to a variety of habitats, including upland forest, shrub-riparian, and rocky outcrop. These habitats will be most appropriate for wildlife use, with some potential for traditional and recreational use.

3.4.5 Reclamation Goals

The goals during decommissioning and reclamation are to:

- Remove all equipment and buildings not necessary for future use and care of the site,
- Stabilize the terrestrial environment and replant native vegetation where applicable,
- Minimize disruption to the marine environment, and
- Restore land use potential.

Specific activities to be conducted during the decommissioning and reclamation process are described in further detail in the following sections.

3.4.6 Removal of Equipment and Infrastructure

Following the completion of quarrying activities, estimated to be sometime after 2070, the site will be decommissioned as outlined in the reclamation plan (Section 3.4.2). As part of this plan, all equipment and related infrastructure including the processing plant, machinery and equipment will be removed from the site. The purpose of removing the equipment and infrastructure is improve site aesthetics and allow the site to return to a more natural looking state, while at the same timing decreasing the potential for environmental risk over the long-term if these materials were left on-site.

It should be noted that following de-commissioning the land-owner, the MODG, may request that some infrastructure be left on-site that might be beneficial for future land uses. It is anticipated that discussions with MODG regarding final reclamation and decommissioning of the site will take place as the operation nears completion.

Equipment and infrastructure to be removed include:

- Mobile equipment including trucks and loaders;
- All conveying, crushing and screening infrastructure, including:
 - Primary, secondary and tertiary crushers;
 - Conveyors and control towers;
 - Wash tower and screening facilities;
 - Pump facilities and pipes from settling ponds
- Surface buildings not required for future land use by MODG, including office facilities and maintenance buildings and equipment sheds;
- Infrastructure including:

- septic system(s);
- fuel storage facilities;
- Any garbage, waste and debris will be disposed of in an approved waste disposal site;

Factors to be considered during removal of equipment and infrastructure include:

- Minimizing lag time between retirement of buildings or structures and their disassembly;
- Keeping retired buildings closed to discourage colonization by wildlife;
- Disassembling buildings and structures outside of the breeding season for most birds (April 1 to September 1). Alternatively, inspecting buildings or structures just before disassembly to ensure they are not being used for nest sites in compliance with Migratory Birds Convention Act. Otherwise perform nest surveys and limit activities until nests are no longer occupied. Also contact relevant authorities prior to site decommissioning (e.g., Canadian Wildlife Service);
- Minimize lag time between completion of aggregate production and commencement of equipment and infrastructure removal.

Following the removal of all equipment and infrastructure, the plant site and administrative areas will be graded to allow for future commercial, industrial, recreational, or residential land use, or to allow for restoration of the area for wildlife habitat.

3.4.7 Removal of the Marine Terminal

To avoid disturbance of the marine environment and enhance its potential for future use, the rubble mound, mooring dolphins, caissons, slewing rails, and buoys will likely be left in place. The shiploader arm and ancillary mechanical equipment including suspended conveyors, dust collectors, drive belts, and shuttle will be removed from the Project site.

3.4.8 Site Rehabilitation

The Proponent will undertake a progressive reclamation program at the Project site during operations, which will include the use of Best Management Practices developed for quarry facilities; only the area needed for production in any one year, would be grubbed. The subsoil, topsoil and root mat of this area would be placed in a dedicated stockpile and similarly, any overburden would be stockpiled separately. This material will be used in future reclamation. The reclamation process begins after the environmental controls are in place.

Hydroseeding stockpiles may be used as an alternative to the use of root mat in future activities. This approach will provide a source of native plant species which are well adapted to local climatic and soil conditions, while also reducing the need for fertilizer use. If it is necessary, seeds of native plant species which are well established to Nova Scotia and which are not aggressive weeds in the local plant communities of the Project site will be used to stabilize soils during reclamation. This option will be used in the event that grubbed material has not produced sufficient plant biomass to stabilize soils. Re-vegetated areas will be monitored for up

to 5 years after decommissioning to ensure that a self-sustaining vegetation cover is successfully established.

As distinct areas of the quarry become inactive, these areas will be graded to a stable slope of 2:1, covered with overburden, and (if warranted) seeded in the absence of laying a root mat. Within six (6) months of abandoning quarry operations, the rehabilitation of the site will have achieved:

- grading and contouring of all slopes and exposed rock faces, to the extent practical, in consideration of rock falls, slope stability, and safety;
- spreading stockpiled overburden and topsoil; and
- hydroseeding in the absence of laying a root mat.

The laydown (covered with quarried materials) and administrative areas (following the removal of all structures) will be graded, as required to allow for future commercial, industrial, recreational, or residential land use, or to allow for restoration of the area to existing conditions (wildlife habitat). An example of the potential end use is shown on **Figure 3.0-30**.

An Environmental Management Plan (EMP) will be developed for the Project and will include a number of mitigation measures that will address aspects of the Project including site rehabilitation. The Project EMP will ensure Project activities adhere to all relevant federal and provincial regulations (e.g. *MBCA*, *SARA*, etc.).

3.4.9 Reclamation Phasing Timeline

The following table provides an estimated timeline for reclamation activities.

Table 3.9
Reclamation Phasing Timeline

Activity	Anticipated Start Date	Anticipated Completion Date
Best Management Practices	2018	2070+
Operations	2021	2070+
Decommissioning (Equipment, Plant, Marine Terminal)	2070	2072
Reclamation	2072	2073
Monitoring and Acceptance	2073	2078

3.5 ACCIDENTS AND MALFUNCTIONS

Malfunctions and accidental events will be prevented and mitigated through a systematic approach to worker health and safety and environmental protection. Contractors will be required to submit health and safety policies and plans to the Proponent for review and approval prior to any onsite activities. Onsite workers will receive appropriate training to prevent and mitigate workplace accidents and environmental upsets.

The accidents and malfunctions that could potentially occur during site preparation and construction, any phase of operations, and the site decommissioning and closure phases of the Project are described below, while accident scenarios are described systematically in Section 7.18. Mitigation measures to prevent the occurrence of such events, and response procedures to be implemented in the event they do occur, are also described in Section 7.18 and will be developed in more detail as part of the Industrial Approval application process.

3.5.1 *Fuel and Hazardous Materials Spills*

Quarry, Plant, Shop and Loadout Areas

All phases of the Project (site preparation, construction, operation, closure and decommissioning) will include the use of fuels and equipment maintenance and servicing fluids. The fuels will include diesel fuel and gasoline required to operate the mobile equipment and portable generators (note: the generators will be discontinued following Phase 3). The equipment maintenance and servicing fluids include hydraulic oils, various viscosity grades of oils and lubricants, greases, antifreeze, brake and steering fluids, small quantities of other maintenance aids such as paints, WD40, and other solvents. Site development and quarry operations will also use blasting agents that may include diesel fuel and ammonium nitrate as components.

The potential for spills or leaks of any of these materials exists during all phases of the Project. The spills could result from equipment failure, damage to storage or piping systems, mobile equipment accidents, or failure to follow proper procedures related to fuel and other bulk material transfers or equipment maintenance activities. In the unlikely event of a large spill or leak, soil, groundwater and surface water contamination may occur, adversely affecting the quality of habitats and/or resulting in ingestion or uptake of contaminants by wildlife.

The risk to the environment from spills or releases of fuel and other substances is mitigated through a series of activities and controls. Any large spill event would be associated with materials stored in bulk quantities at the maintenance shop, primarily fuels and some lubricating oils. Materials stored on site in bulk will be stored in above ground storage reservoirs with secondary containment in compliance with provincial regulation. Any spillage inside the containment will be recovered and managed in accordance with provincial waste management requirements.

The processing plant area is designed to provide protection from fuel or other material spills. The main processing plant and shop area will be sloped to the south so that any spilled liquids will remain on-site. Larger spills could potentially be directed to the processing plant settling basins where the spilled material would be recovered. In the event that a settling basin is used to manage a large spill, the basin pump used to provide wash water would be shut off until the

spilled material has been recovered. In all cases, the spilled material will be contained and recovered as quickly as possible.

As required by workplace health and safety regulation, the employees working at Black Point will be trained in spill response procedures. Spill response materials (absorbents, pads, socks, booms) will be available in proximity to areas where fuels and other materials are located. Most spills or leaks will be localized near the source and be addressed by site personnel using the available spill response equipment. All fuel, chemicals and wastes will be handled in a manner that minimizes or eliminates the risk of spillage and accidents. In the event of any spill or leak at the site, immediate action will be taken to stop the leak and contain the spilled material. All contaminated material will be collected and stored in an appropriate manner so as to not result in a re-release to the environment until such a time as it will be transported to an approved treatment / disposal facility. All spills will be reported to the 24-hour environmental emergencies reporting system (1-800-565-1633) in accordance with the *Emergency Spill Regulations* enacted under the Nova Scotia *Environment Act*. As well, spills that contravene the provisions of CEPA 1999 will be reported to a federal enforcement officer and the public as required under CEPA 1999 (s. 212). A Spill Contingency Plan will be developed in support of the application for provincial Industrial Approval.

The Black Point facility will use best practices during fuel and other liquid transfer operations including monitoring and oversight of the transfer activities and verification to ensure that the receiving container has adequate capacity prior to beginning the transfer procedure. Tanks will be designed with level monitoring and overflow protection in accordance with prevailing provincial regulations.

All Project equipment and vehicles will meet industry standard requirements and be safety certified and fit for their intended use. Regular pre-shift inspections and maintenance programs will ensure the continued reliability and integrity of Project equipment. Necessary critical spares will be maintained in the event that an equipment change-out is required.

The Proponent will have a written agreement in place with a certified emergency response company (e.g., Emergency Services International; Kildoon Emergency Management Training) to provide land and water based spill response services prior to the initiation of Project construction activities.

Marine Terminal and Ship Operations

The risk of a fuel or hazardous substance release at the marine terminal is minimal because the facility will not be transferring fuel, ballast water, sewage, ship waste or any other material apart from the crushed stone aggregate between the ship and shore.

The ships will arrive “ballasted” and ballast water will be discharged during the loading. Ballast discharge is governed by the *Canadian Ballast Water Control and Management Regulations* (SOR/2011-237) as well as the International Marine Organization (IMO) International Convention for the Control and Management of Ships’ Ballast Water and Sediments. Compliance with the regulations and guidelines minimizes the risk of transfer of invasive species due to ballast water. Ships are required to comply with the ballast water exchange regulations unless they have a ballast water treatment system on board or retain ballast within the ship.

The requirements regarding ballast exchange vary based on the ship's route of travel and origin. Ships that originate and took on ballast water within waters under Canadian jurisdiction are not required to exchange ballast water before discharging. Ships originating outside of Canadian jurisdiction that took on ballast water outside of Canadian waters are required to exchange the ballast water at least 200 nautical miles outside of Canadian waters in water at least 2,000 deep. Ships coming into Black Point will be required to comply with the *Canadian Ballast Water Control and Management Regulations* and to maintain a Ballast Water Management Plan. The enforcement of these requirements is the responsibility of Transport Canada.

There is a potential for liquid spills or releases in the event of an accident that results in damage to the ship's hull sufficient to rupture a fuel tank, bilge water tank, or other ship structure that contains fuels, lubricating oils, hydraulic fluids, bilge or ballast water. Such an incident would release the affected material into the coastal waters. Factors such as the spill volume and composition, wave, current and wind conditions, and the promptness and effectiveness of response efforts would affect the extent of impact associated with the event. These impacts may include damage to fisheries, impacts to aquatic flora and fauna and waterfowl, as well as coastal impacts from residual material coating the shoreline (please see Sections 6.11 Shipping and Navigation and Section 7.18 Accident and Malfunctions for more detail on these subjects).

The likelihood of a ship-to-ship collision event is low given the lack of significant large shipping traffic in the area of the marine terminal. A collision with a fishing vessel would not likely result in damage severe enough to cause a release. The predominant fuel used by Project vessels is marine diesel; this material is responsive to spill control agents and standard spill response measures. The Project will mitigate this risk by ensuring that ship docking at the terminal is tug and pilot assisted as needed and required by law, the terminal and mooring structures are properly constructed and well lit, and also by having a written agreement with a certified spill response contractor to provide response services in the event of a spill affecting the marine environment. Other mitigating factors include continual redesign of vessels being produced to make them less susceptible to collision damage. This will reduce this risk over the life of the Project. As previously noted, an Emergency Spill Response Plan and emergency response training will also be employed at the site.

3.5.2 Erosion and Sediment Control Failure

The laydown area containing stockpiled materials will be designed to contain and direct runoff to the settling ponds and, under normal weather conditions, it is anticipated that there will be no water discharge from the operation. The engineered settling ponds cannot "fail" in the sense of a wall breach since they will be excavated into rock and bermed with several tens of meters of stone. The ponds may overflow, particularly during a prolonged or significant (i.e., 100-year) storm event but this overflow would not reach the ocean. In the event of an overflow, water would be contained within the site due to the south facing slope of the lower platform. The two ponds together will hold approximately 12,200 m³ (approximately 3 million US gallons). Calculations indicate the lower platform can accommodate over 28,000 m³ of water. This would flood a small portion of the lower platform to an approximately depth of 30 cm. Such a flood would temporarily halt operations in this area but would not, for example, affect processing plant machinery. This flooding would only occur if the electricity failed; should the electric pumps continue to function during a severe storm, then water can be transferred between the settling ponds and the pit sump. The water would be retained in the pit sump until clear, then tested and discharge if needed, or returned to settling ponds.

Additional temporary or permanent retention ponds may be installed elsewhere on the site during construction as required in NSE's Erosion and Sedimentation Control Handbook for Construction Sites (NSE 1988).

These areas, and erosion and sediment control measures installed elsewhere in the Project area, will be regularly inspected and monitored, particularly during and after extreme precipitation events. Erosion and sediment control structures found to be damaged will be repaired immediately and any other remedial action will be taken as necessary. Fines storage areas will be confined to areas within the quarry pit so any control failures would not result in an off-site release of material.

3.5.3 Vehicle and Vessel Collision

Vehicle Collisions

Vehicular collisions may occur during any phase of the Project. The vehicles operating at the site will primarily be Project related mining equipment including bulldozers, haul trucks, loaders, service vehicles (pick-up trucks) and company cars. Any vehicles accessing the site will be required to have stated business and check-in at the office or scale house. Traffic patterns, speeds, and right-of-way signage and training will minimize the risk of vehicle collisions on the Project property. Operators of mobile equipment will receive initial and annual training on safe equipment operation and on issues such as awareness of blind spots.

Vessel Collisions

The risk of vessel collisions is primarily associated with Phases 3 through 5. There is the potential for Project related vessel collisions during construction and other operating periods and decommissioning, but the limited amount of marine activity during those phases reduces the potential risk. The management of marine traffic in Chedabucto Bay is under the responsibility of the Canadian Coast Guard. It is mandatory that all large vessel traffic report to the Canadian Coast Guard at specified points and take local pilots on board. The potential for collisions will be minimized through controlling vessel speed; scheduling and coordinating activities with other marine users, Transport Canada and the Canadian Coast Guard; and posting Notices to Mariners as needed. The marine terminal will contain navigational aids and anti-collision radar will provide early warning of a potential collision hazard. The Project will also use weather reports and wind speed information to monitor for changing weather conditions that could increase the risk of collisions during vessel navigation to or from the terminal. This mitigation measure will provide a level of protection in addition to that provided by the Coast Guard and the use of tugs and pilots for navigation support (please see Sections 6.11 Shipping and Navigation and Section 7.18 Accident and Malfunctions for more detail on these subjects).

3.5.4 Fire

A fire at the Project site may occur during any phase of the Project due to an equipment accident, human carelessness, or natural causes such as a forest fire or lightning strike under dry conditions. The immediate concern for a fire is for human health and safety; additional concerns include habitat loss, direct mortality to wildlife, and loss or damage of property. The emissions from a fire would likely consist mainly of smoke (particulate matter) and CO₂, but could also include CO, NO_x, SO₂, and other products of incomplete combustion. A large fire could create air contaminant levels greater than the ambient air quality standard over distances

of several kilometres; however, the likelihood of such cases is considered low and the event would be of short duration.

The risk of fire will be reduced by proper management of fuel and other flammable materials, and through appropriate operational procedures such as industry standard storage, handling and transfer techniques. The Emergency Response and Spill Contingency Plan, which will be prepared under the Environmental Management Plan as part of the Industrial Approval application process, will outline procedures for fire prevention, response and reporting. In the unlikely event of a large fire, local emergency response and firefighting capability will be called to respond to reduce the severity and extent of damage and to protect the safety of workers.

3.5.5 Health, Safety and Environmental Management

A Project-specific Environmental Management Plan (EMP) will be prepared to describe the procedures required to meet regulatory obligations and mitigating measures and commitments made in this EIS. The purpose of the EMP is to:

- Ensure that the commitments to minimize environmental effects in general, and specific regulatory commitments and commitments and mitigating measures made in this EIS will be met;
- Provide concise and clear instructions regarding procedures for protecting the environment and minimizing potential environmental effects;
- Document environmental concerns and appropriate protection measures associated with Project activities;
- Provide a reference document for planning and / or conducting specific activities which may have an effect on the environment;
- Function as a training document / guide for environmental education and orientation; and
- Communicate changes in the program through the revision process.

Environmental management is considered an integral element in the way daily activities are undertaken. The Proponent is committed to upholding this position while complying with commitment as well as detailed Project requirements for environmental management to staff, contractors, regulatory agencies and the public. Those involved in the Project will then incorporate the environmental management practices into their daily work routine. The EMP will be used during site preparation and construction (and decommissioning and reclamation) and normal operating conditions at the site. The EMP will also detail the various monitoring programs to be undertaken before (baseline), during (compliance and environmental effects), and after the Project (ongoing environmental effects).

Development of the EMP will be done in consultation with regulatory agencies and will be completed in advance of the commencement of site preparation and construction.

Environmental Management Plan Draft Table of Contents

- 1. Introduction
 - 1.1. Commitment to Environment, Health and Safety
 - 1.2. Purpose of the Environmental Management Plan
 - 1.3. Scope, Organization and Maintenance
- 2. Responsibilities and Training
 - 2.1. Environmental Management and Communications
 - 2.2. Roles and Responsibilities
 - 2.3. Training and Orientation Requirements
- 3. Summary of Key Environmental Issues and Environmentally Sensitive Areas
 - 3.1. Marine Construction
 - 3.2. Marine Fish and Water Quality
 - 3.3. Marine Species at Risk
 - 3.4. Wetlands
 - 3.5. Watercourse Alterations
 - 3.6. Terrestrial Fish and Fish Habitat
 - 3.7. Terrestrial Species at Risk
 - 3.8. Recreational and Commercial Fishing
- 4. Environmental Protection Procedures (EPP)
 - 4.1. Project Operation
 - 4.1.1. Generic Mitigation Measures and Best Management Practices
 - 4.1.1.1 *Generic Best Management Practices*
 - 4.1.1.2 *Erosion and Sediment Control Plan*
 - 4.1.1.3 *Stormwater Management Plan*
 - 4.1.2. Site Preparation Activities
 - 4.1.3. Watercourse Access Installation and Removal
 - 4.1.4. Marine Construction Activities
 - 4.2. Operations, Monitoring and Maintenance
 - 4.2.1. Inspections and Bird Monitoring
 - 4.2.2. Surface Water Discharge Monitoring
 - 4.2.3. Groundwater Monitoring
 - 4.2.4. Other Environmental and Compliance Monitoring
- 5. Waste Management
 - 5.1. Introduction

-
- 5.2. Waste Management
 - 5.3. Equipment Fuelling and Hazardous Materials Management
 6. Environmental Monitoring
 - 6.1. Baseline Monitoring
 - 6.2. Compliance Monitoring
 - 6.3. Environmental Effects Monitoring (EEM)
 7. Emergency Response and Spill Contingency and Plans
 - 7.1. Spills
 - 7.2. Vessel Collision
 - 7.3. Fires
 - 7.4. Heritage and Archaeological Discovery
 - 7.5. Erosion Control Failure
 8. Incident Reporting
 9. Contact List
 10. References

Sections 1 and 2 of the EMP will introduce the EMP and provide the overarching objectives, scope and organization of the document (Section 1) as well as the organizational structure for environmental management and the roles and responsibilities of key personnel (Section 2). Section 3 will provide a brief overview of the key environmental and socio-economic issues and concerns specifically associated with the Project.

Sections 4 and 5 of the document will include specific mitigation measures for various activities associated with each phase of the Project to ensure protection of the environment. This will include regulatory requirements, commitments made in this EIS. Mitigation measures will be provided based on standard construction practices and will be adapted as required to meet the specific needs of the Project and the area. For example, the EMP will include / indicate:

- The appropriate timing of in-water works;
- Pre-construction meeting requirements;
- Erosion and sediment control and storm water management;
- Requirements for vessel speeds and course;
- Site restoration and stabilization procedures;
- Spill prevention and response procedures; and
- Waste management and fuelling procedures.

Section 6 of the EMP will include the details of the various monitoring programs to be undertaken. These programs will be developed in consultation and co-operation with regulatory

agencies such as DFO and will include (among other information) descriptions of the equipment to be used, the frequency of the monitoring and reporting requirements.

Baseline monitoring in the Project area has begun and the data collected was used in support of this EIS. Additional information will be collected in advance of Project construction to build on initial work and help characterize pre-development conditions.

Compliance monitoring will be conducted throughout site preparation and construction, operations, monitoring and maintenance, and decommissioning and reclamation phases of the Project. Compliance monitoring is intended to ensure conformity with municipal, provincial, and federal legislation and any conditions of approval to the EIS imposed by regulatory agencies. Monitoring frequency will be at regular intervals, and in response to significant storm events to ensure erosion control structures are functioning. Monitoring and inspection personnel will also be available to provide guidance and support during construction in sensitive areas and / or during sensitive periods.

Section 7 of the EMP will include various contingency and emergency response plans for both land and marine activities. Section 8 will outline the incident reporting requirements and will provide the format and information that must be provided with each report. Incident reporting will include spills reporting and wildlife sightings.

Section 9 of the EMP will include a list of Proponent contacts and the various regulatory agencies that have and / or will be involved through the Project as well as emergency contacts.

4.0 ALTERNATIVES TO THE PROJECT

4.1 Do Nothing Alternative

The alternatives analysis uses a systematic approach to evaluate different methods of achieving the Project's goals. Each technically and economically feasible alternative is in turn subject to further analysis within the EIS report. The Project consists of the quarrying, crushing and marine transport of granite aggregate. Ultimately, the Project is intended to meet market demand for aggregate and bring value to the Proponent's shareholders and to local area residents.

The Proponent's economic analysis supports the current Project description and suggests that it is the most practical and economically feasible approach to this development (Erdene 2011). Given this, the only alternative to this undertaking is to not undertake the Project at all, referred to as the "Do-Nothing Alternative". Not implementing the Project would naturally result in the non-fulfillment of the Project's goals and is thus not an economically feasible alternative. Implementing the Project as proposed will result in residual positive and adverse environmental effects, but significant adverse effects are not likely to occur (please see Section 12 of this report). The Project is also expected to provide long-term local and regional economic benefits as described in Section 7.13 of this report. Without the Project, neither the adverse effects nor the economic benefits would be realized.

4.2 Assessment Methodology

In the sections that follow, alternative means of undertaking the Project are described. Only those alternative means that are technically and economically feasible are further assessed with respect to their potential environmental and socio-economic impacts.

As a minimum the EIS Guidelines (CEA Agency 2014) require an alternative means assessment of the following subjects:

- Rock material extraction method
- Transportation methods/routes
- Construction methods for the marine terminal including management options for dredged material (on land versus at sea)
- Location of the marine terminal
- Location of stockpiles
- Location and type of waste management facilities
- Means of electrical generation

In addition to the components above, alternative quarry locations were evaluated and alternative quarrying methods were examined. Technical feasibility was assessed by the Vulcan project team based on their extensive experience at more than 200 operating quarries in the US Mexico, and the Bahamas. The relative economic feasibility each alternative was assessed based on anticipated capital, operating and lifecycle costs.

As outlined in the EIS Guidelines, the assessment methodology consisted of:

1. Determining the technical criteria by which feasibility is determined and using these criteria to identify and describe the technically and economically feasible alternative means to carry out the Project;
2. Establishing through qualitative means which of these alternatives is in fact technically and economically feasible;
3. Identifying the VCs potentially affected by each alternative means and examining the effects of the alternatives on each VC. This is undertaken with a specific focus on both environmental effects and effects on potential or established Aboriginal and Treaty rights and related interests.
4. Identifying the preferred means for undertaking the Project.

4.3 Alternative Quarry Locations

A multi-year aggregate exploration and reconnaissance program was undertaken by the Proponent to investigate potential quarry sites in the Maritimes, concentrating on Nova Scotia due to its southerly location with respect to markets on the US east and Gulf coasts. This program included literature research and site-specific evaluations of existing physical, biological and socio-economic conditions. The following technical criteria were evaluated for potential sites:

- Geological resource suitability;
- Size and availability of site;
- Proximity to deep, ice free, sheltered water;
- Engineering feasibility;
- Presence or potential for environmental constraints such as species at risk, fish habitat and wetlands;
- Zoning, proximity to residential development and existing transportation networks;
- Economic diversity and sustainability; and,
- Presence or potential for unique heritage resources.

Because aggregates are a high-bulk low-cost commodity, the cost of transportation can easily exceed the price of the aggregate. So, for a marine quarry that requires considerably more capital than a land-based quarry to be profitable, the aggregate source must be located immediately adjacent to deep water and capable of being transported to the ship by conveyor. If trucks or rail are required to transport aggregate from the quarry to the wharf, the project would be uneconomical. Using these technical criteria, no other suitable alternative sites were found during the course of the exploration and reconnaissance program.

Insofar as no other economically viable sites were identified, the key VC affected by an alternate location would be Local Economy, Land and Resource Use. Alternate Project sites would presumably also impact other VCs related to the natural and human environment.

The key technical criteria which led to the selection of the Black Point Quarry Project site are:

- Availability of high quality, large tonnage, fine-to-medium grained, homogenous granite that meets or exceeds all of the necessary physical and chemical requirements to produce Class-A construction aggregate;

- Deep (>14 m), sheltered, ice-free bay for the location of the marine terminal to enable shipping of processed aggregate rather than trucking products through populated areas;
- Minimal to no overburden on the Project site, reducing development costs and limiting the potential for sedimentation during construction and operation;
- Proximity to well-traveled international shipping lanes with existing logistical support, such as pilot tugs; and,
- Appropriate zoning with no fundamental environmental or regulatory constraints, based on a preliminary review.

With Black Point, Guysborough Co. as the only technical and economically feasible location for the granite quarry, the following sections describe and evaluate alternative methods for undertaking the Black Point Quarry Project with respect to location and construction of the marine terminal and operational design aspects of the quarry.

4.4 Rock Extraction Method

Technical criteria to determine the feasibility of alternate extraction methods include simple practicality. Drilling and blasting is the proposed approach for material extraction from the Black Point Quarry. Alternative mechanical methods of rock extraction (e.g., ripping) are not practical or feasible due to the extremely hard and dense characteristics of the granite. Therefore, there are no feasible alternatives to drilling and blasting as a means of extracting this material. The VCs impacted by the alternatives rock extraction methods would be similar in both cases: both methods would result in noise and particulate emissions to air.

The differences in these methods relative to noise and particulate emissions are that ripping involves the use of heavy equipment with hardened metal teeth that essentially scrapes into the rock from above and along the front wall face. The noise created during ripping would be extreme due to the fact that granite ripping would be a slow process and continuous, requiring multiple machines to generate the amount of material needed to feed the process. The ripping process also would be a continuous source of dust emissions. In the case of drilling and blasting, the drilling process does not generate noise at such levels and the drill rigs include equipment to collect or reduce dust generated by drilling. Blasting is a very short duration event that is capable of generating ample amounts of stone to supply the plant; blasts only occur a few days a week at the most. Ultimately, the Black Point operation would not be economically feasible without the use of drilling and blasting.

4.5 Development and Transportation

Alternative site design and transportation methods/routes considered for the Project include:

- Development of a rock face open pit and progression in a southerly direction with transport of blasted rock to the processing area via large truck or conveyor system; and,
- Development of a glory hole open pit (from the top down) with transport of blasted rock to the processing area via a conveyor system with a tunnel.

Technical criteria to determine the feasibility of alternate site design and transportation options include worker and equipment safety, economics and practicality. The primary VC affected by

alternate site design and transportation options is Local Economy, Land and Resource Use. Due to worker safety concerns, operational issues and geotechnical considerations, the glory hole alternative consisting of a near vertical ore pass and underground horizontal portals was deemed not technically feasible. This option is also considerably more costly and so is not economically feasible when compared to the rock face approach.

The technical and safety challenges of the glory hole approach relate to the fact that all the stone produced would be dropped into a vertical shaft to a stockpile at the base of the hill. Rocks will frequently jam within the shaft, requiring blasting or other methods to free the blockage. The risk of injury or death to employees due to accidents involving workers trying to remove blockages as well as operating at the feed point and bottom stockpile area is not acceptable to Vulcan. The glory hole method would also generate higher levels of dust emissions and noise due to the fracturing created by the rock falling through the glory hole and then impacting the rock in the lower stockpile. The rock movement would also displace large volumes of air that would make it difficult to control the dust emitted from the operation.

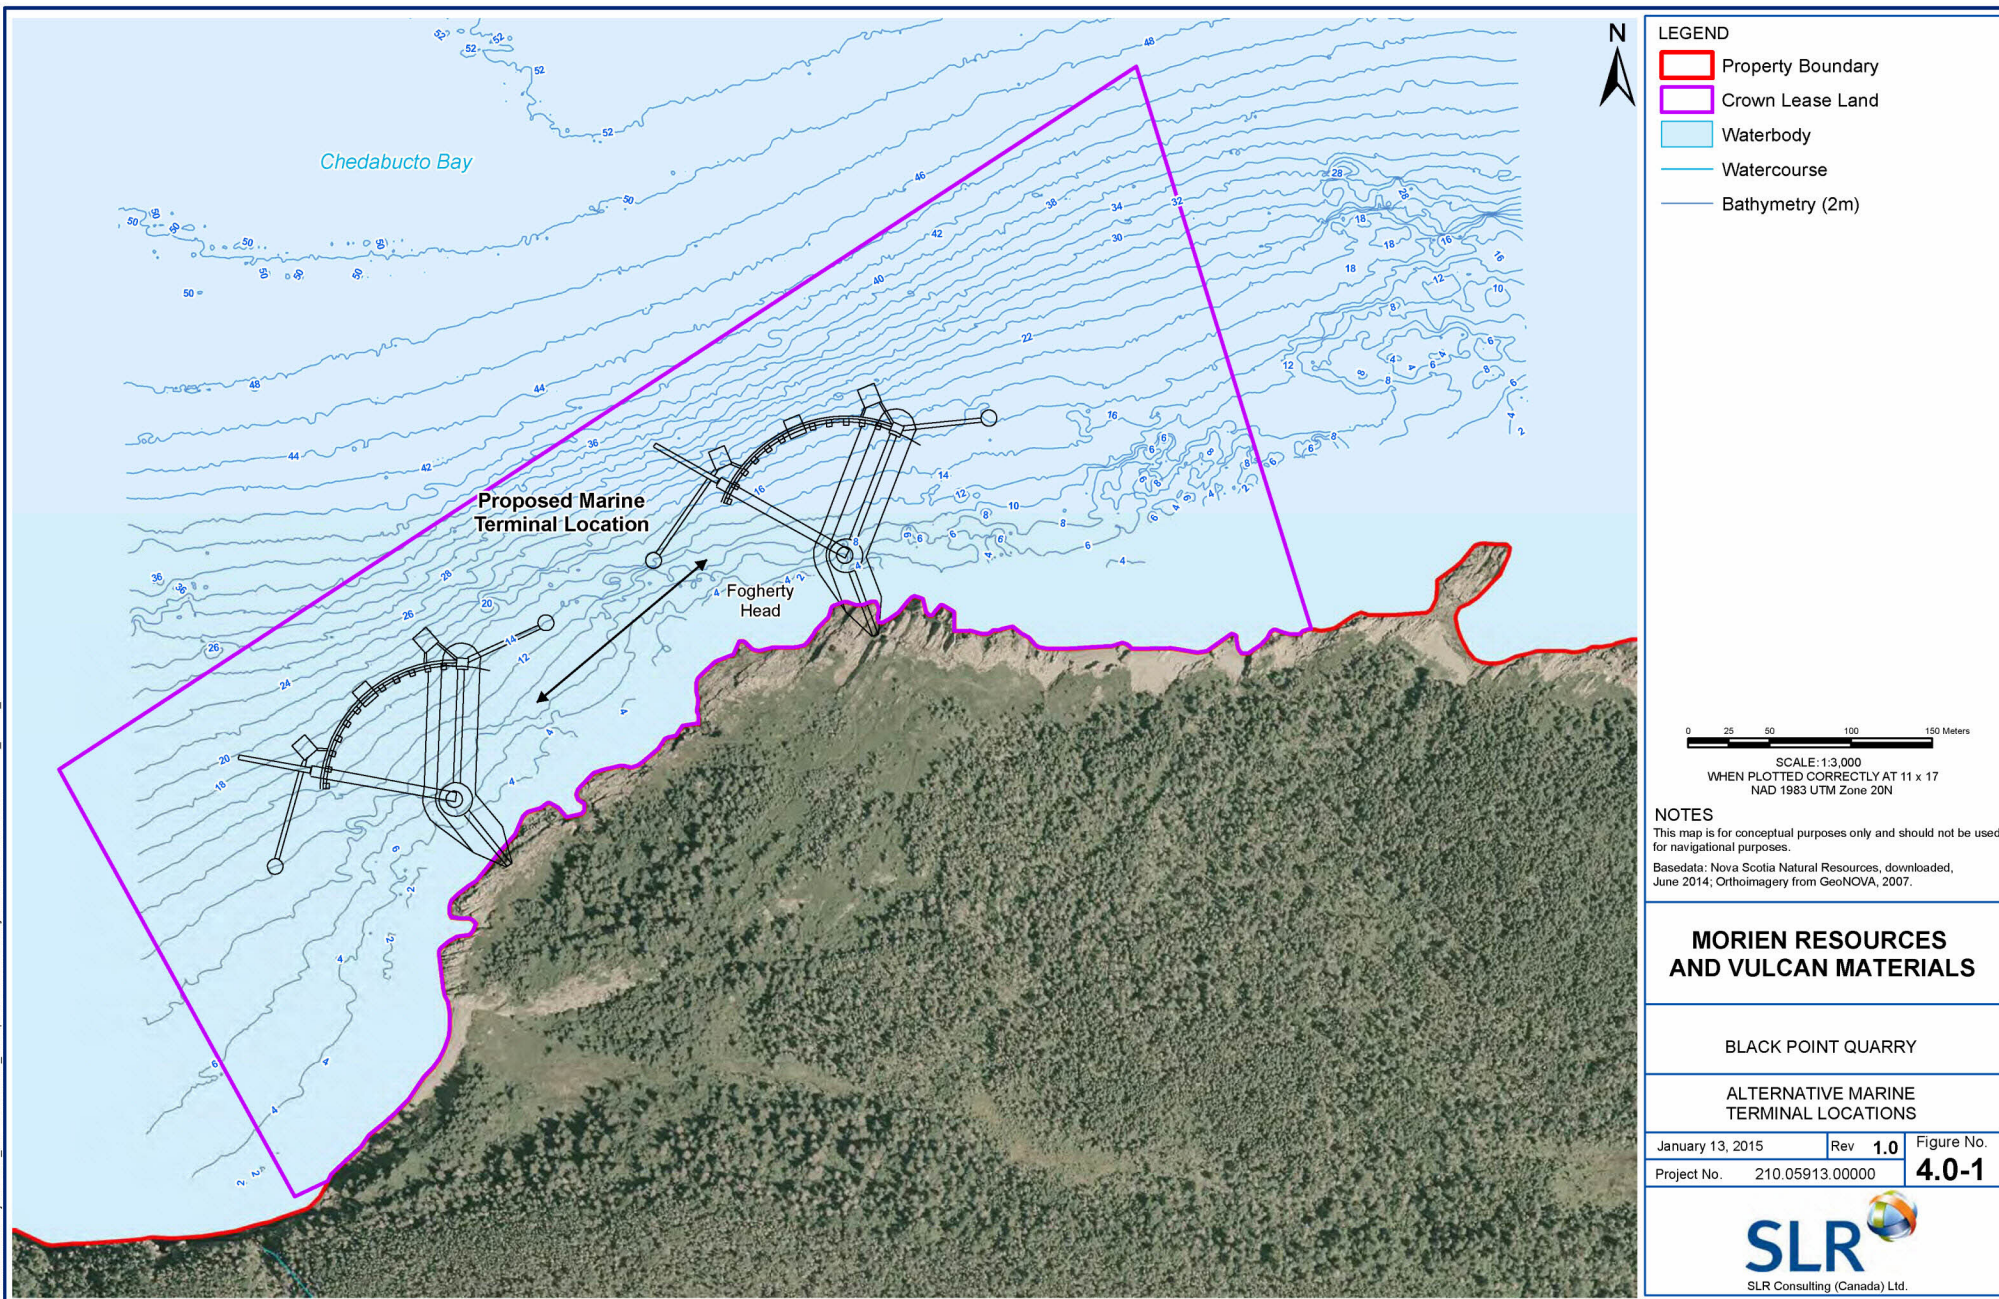

In contrast, the use of haul trucks and conveyors for material transfer is well established, well understood, and much easier to manage. The methods for controlling dust emissions are effective and easy to implement, and the equipment can be safely operated by trained personnel.

While there are existing bulk terminals in the Strait of Canso, all are too far from the proposed quarry to be of economic use. The cost to transport a tonne of aggregate by truck is about \$0.15/km therefore, transporting material 50 km or so to the Strait would cost over \$7.50/tonne, essentially doubling the cost of the aggregate. In addition, transport of aggregate to the Strait would require high frequency truck traffic through several communities, which would likely raise significant concerns from local residents and add a cost burden for road repairs to the municipality. Other negative factors associated with off-site truck transport include the impact of heavy truck traffic on road durability as well as the potential for vehicle accidents due to the increase in heavy vehicle traffic on local roads. Another major factor affecting the economics of overland transport is the limitations of truck transport imposed by winter conditions including icy roads and snow storms.

4.6 Marine Terminal Locations

The Proponent has considered alternate locations for the marine terminal. Technical criteria to determine the feasibility of alternate marine terminal locations consist primarily of navigational and operational safety considerations. The primary VCs affected by alternate terminal locations are Marine Species and Habitat and Commercial Fisheries and Aquaculture, although for the most part, different marine terminal locations affect these VCs in much the same way.

Based on feedback from local fishermen, the terminal should be located as far west as possible to increase the sheltering effect from wind and strong currents off Black Point. However, this location is not practical since the bathymetric profile to nearshore area is too shallow (15-20 m vs 25-30 m at the preferred location). The originally proposed terminal site and the proposed range of alternative sites are presented in **Figure 4.0-1**. The selected alternative is the easternmost location. Following multiple meetings and discussions with the local fishermen, the selected location of the marine terminal is the preferred location to minimize impacts to fishing areas.

4.7 Marine Terminal Construction Methods

Alternative construction methods for the marine terminal were investigated in order to reduce disruption to marine habitats and minimize costs. Technical criteria to determine the feasibility of alternate marine terminal construction methods consist of constructability, operational safety, operational performance and economic feasibility. The primary VC affected by alternate terminal construction methods is Marine Species and Habitat.

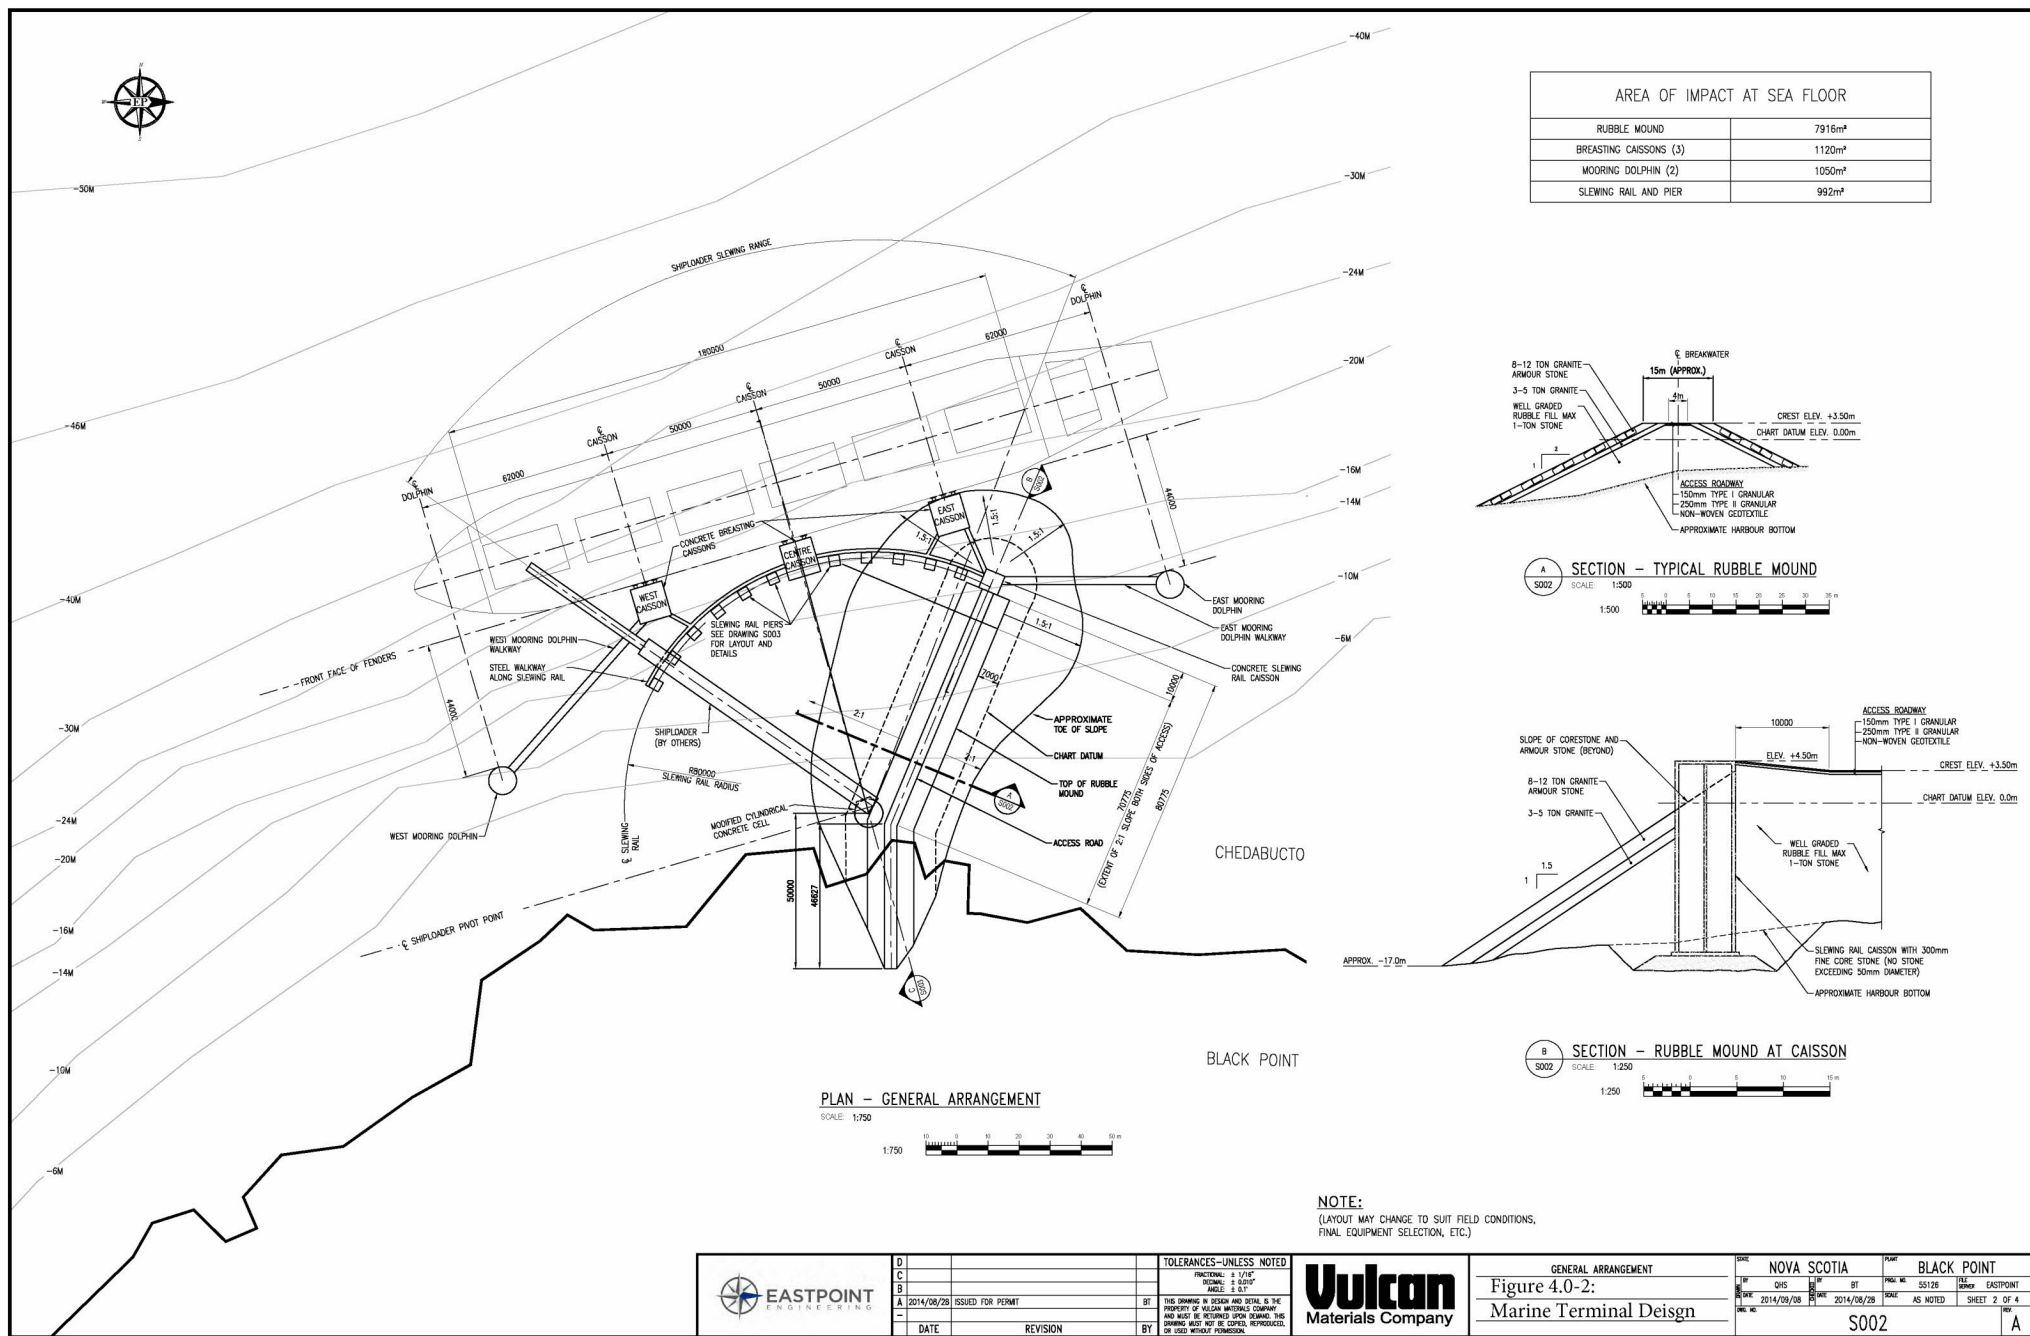

Two approaches to wharf construction were considered: the rubble mound approach and the concrete caisson approach. The rubble mound approach uses rock generated on site to form a continuous base upon which a wharf is constructed. In contrast, the caisson approach uses separate steel or concrete box-like forms (the caissons) to form pillars that support the wharf. Neither method requires in-water blasting or dredging although the caisson approach requires percussion (pounding) to install foundations into the seabed.

The rubble mound has a simpler design and is less expensive to design and build, and thus more cost effective. In addition, it permits the secure storage of any potentially acid-generating rock that may be present once the lower platform has been levelled for plant construction. The underwater storage of potentially acid-generating rock prevents acid formation and is a preferred management option for this material, should this be encountered during site construction.

The rubble mound is potentially more stable in rough weather and has lower maintenance costs over the long term. Most importantly, it is considerably more operationally efficient, since it allows for vehicular traffic and access to support maintenance of the ship mooring points. The caisson approach does not allow for vehicles and so maintenance would be conducted by boat, which is more expensive and potentially more dangerous.

The rubble mound typically occupies more of the seabed than the caissons and so it potentially affects more marine seabed habitat. Caissons also occupy seabed (to a lesser degree) but the wharf connecting the caisson would shade the seafloor, negatively affecting habitat quality and use. The rubble mound in time is expected to act as lobster habitat where the caisson method would not have a similar benefit.

Given the advantages of the rubble mound approach, in terms of constructability, operational safety, operational performance and economic feasibility, this design is chosen over the caisson approach. We underline that this approach will be used to construct the wharf beginning at the shore and extending to the ship mooring infrastructure. For mooring, ships will be attached to three mooring caissons as shown on **Figure 4.0-2**.

4.8 Stockpile Locations

Alternative stockpile locations were evaluated primarily to minimize costs and to limit potential impacts to wetlands. Technical criteria to determine the feasibility of alternate stockpile locations consist of operational performance and economic feasibility. The primary VC affected by alternate stockpile locations is Wetlands, since other VCs, such as Marine Species and Habitat and Commercial Fisheries and Aquaculture, would be equally affected (to a very limited degree) no matter which alternative was selected.

Stockpiles are proposed for the western portion of lower platform, adjacent to Chedabucto Bay and opposite the marine terminal. The alternative option places these stockpiles at the eastern side of the lower platform, adjacent to Chedabucto Bay and within 50 m of Wetland 2. In both alternatives, several wetlands would be lost (e.g., WLs 3, 4, 5 and 6 on **Figure 6.4-2**) but with the second alternative, Wetland 2 is potentially exposed to runoff from the stockpiles. More importantly, this location requires a complete reconfiguration of processing plant and a much longer conveyor system to deliver aggregate to the marine terminal. The preferred location is both operationally and economically more practical, and has the added benefit of lowering the risk of project-related impacts to a large wetland. The stockpile locations have also been selective to mitigate noise emissions from the processing operations thus reducing off-site noise impacts. The stockpiles will also provide a degree of visual screening for the processing plant.

4.9 Waste Management Facilities

There are two types of waste management facilities: a wastewater treatment facility to manage septic waste from site workers, and the berms that will control drainage from the piles of crusher fines (consisting of finely broken rock) generated after washing the crushed aggregate.

With respect to septic waste water treatment systems, technical criteria used to determine the feasibility of different systems include operational performance and, to a lesser degree, economic feasibility. The primary VCs affected by alternate wastewater treatment systems are Groundwater Resources and Marine and Surface Water Resources.

Alternative wastewater treatment facilities were considered but none are as practical, efficient or cost effective as a simple collection tank with follow up transport and treatment at the Canso municipal waste water treatment facility. Alternatives include a conventional septic tank and leach field, above ground systems that use imported, mounded soil to treat waste effluent, the use non-conventional systems such as multiple rotating biological contactors, peat-based treatment systems, constructed wetlands, and recirculating media filters such as sand filtration. Conventional on-site treatment for the 50-60 full time staff would require a large leach field with adequate soil depth above bedrock. These conditions do not exist near the administrative buildings where the washrooms will be located. Non-conventional systems are more expensive to purchase, install and operate, and typically do not perform well, especially in winter. Ultimately, a gravity fed collection tank with off-site treatment was selected as the preferred option, at least initially. The use of a conventional, raised bed system will be investigated once the plant area is accessible. Existing soil thickness and texture will be investigated to determine if the construction of a raised bed treatment system is practical.

Alternate locations for the crusher fines have been considered. The technical criteria used to determine the preferred location includes handling costs (distance from site-of-generation combined with the number of times the crusher fines are moved, once generated), available

surface area, and pre-development habitat type. The VCs affected by crusher fines storage location include: Groundwater Resources, Marine and Surface Water Resources, Terrestrial Ecosystems, Habitat & Vegetation, Wetlands, and Terrestrial Wildlife.

Initially, crusher fines storage was proposed for areas outside of the quarry (**Figure 4.0-3**) but this was later determined to be unnecessarily distant from where this crushed rock will be generated. All waste rock will now be stored within the quarry. This has the additional advantage of ensuring the crusher fines can never be lost to the marine environment.

The storage of the fines inside the quarry also eliminates the potential for storm water runoff releases to the environment and the discharge of fines to surface waters because the quarry stormwater will be contained in the pit. The fines stock piles also can be sources of fugitive dust emissions and so locating them inside the quarry will help to contain these emissions.

Figure 4.0-3:
Alternative Crusher Fines Storage Areas (Orange)

**Figure 4.0-4:
Preferred Crusher Fines Storage Areas (Orange and Blue)**

4.10 Electrical Supply

Significant and reliable electrical power will be required for buildings and the operation of equipment (pumps, conveyors, crushers, screens, and ship loading). The total electrical power demand for the quarry is estimated to be between 10,000 and 12,000 horsepower (i.e., 5.0-6.0 MW), mostly for operation of large electrical motors associated with the processing plant equipment.

Alternative electrical supplies considered for this project include a tie-in to the existing high voltage Nova Scotia Power Inc. electrical transmission line that parallels the southern boundary of the Project site or the use of multiple on-site generators. Technical criteria used to determine the preferred option are operational cost, operational performance, safety considerations, and project emissions (both GHGs and noise).

Over the long term, electricity produced by generators is more expensive than conventional sources due to fuel costs, generator inefficiencies, the need for replacement lubricating oils, and the man-hours dedicated to on-going maintenance. The transport to site, storage and use of fuel for generators increase spill risks to surface and groundwater, and increase the risk of fire or explosion at the site. Project emissions from generators are significantly higher, both in terms of GHGs and noise, when compared to power generators at larger, more efficient power

stations. Given these factors, the preferred option is to tie in to the existing transmission line, rather than use permanent generators to power the site⁵.

4.11 The Preferred Approach

Based on the relative consideration of technical and economic feasibility, likely environmental effects, overall social acceptability, the preferred approach consists of:

1. A granite aggregate quarry located on zoned industrial property in the MODG, near Black Point.
2. Quarrying methods that employ drilling and blasting.
3. Development of the quarry from the north to south, rather than from the top down.
4. Shipping from a newly constructed marine terminal, rather than trucking to an existing marine facility.
5. A largely rubble mound marine terminal located on the western end of the coastal property.
6. Stockpiles located on the western side of the property, facing the marine terminal
7. Off-site treatment of septic waste during initial project phases, possibly followed by the construction of conventional, raised bed septic waste treatment facility.
8. Crusher fines storage area located with respect to minimizing impacts to wetlands.
9. Crusher fines storage within the quarry, rather than exterior to the pit boundaries.
10. Tie in to a nearby electrical transmission line rather than using permanent on-site generators.

Table 4.1 summarizes the alternative means analysis for each component considered above and presents the preferred option selected for the Project.

⁵ Temporary generators will be used during initial project construction phases to provide electricity to administrative buildings while the electrical tie in is being constructed.

Table 4.1
Summary of the Alternative Means of Undertaking the Project

Project Component	Alternative Means	Technical Feasibility	Economic Feasibility	Environmental Effects	Preferred Option
Quarry Location	Black Point Site	Technically Feasible	Economically Feasible	A number of environmental effects are associated with any quarry development; no significant residual environmental effects are anticipated at the Black Point site.	Yes
	Other Nova Scotia Sites	Not Technically Feasible considering the range and specificity of the geographical and resource requirements	Not Economically Feasible based on the Proponent's analysis and given the high-bulk low-cost nature of the aggregate resource	Not assessed since no feasible alternative site was identified	No
Rock Extraction Method	Drilling and Blasting	Technically Feasible	Economically Feasible	Environmental effects are similar in both alternatives: will result in noise and dust impacts. Drilling and blasting has less of an impact due to shorter duration and more established control methods.	Yes
	Ripping	Not Technically Feasible considering the hardness and density of the granite resource	Not Economically Feasible	Environmental effects are similar in both alternatives: will result in noise and dust impacts. Ripping would be more impactful due to more continuous and less controllable dust emissions.	No
Development and Transportation	Rock Face Open Pit	Technically Feasible	Economically Feasible	Environmental effects are largely similar under both mining options	Yes
	Glory Hole Open Pit	Not Technically Feasible primarily due to worker safety considerations	Economically Feasible but additional infrastructure would significantly increase production costs	Potential social (human health) effects are greater in the glory hole scenario due to increased worker exposure to accidents and malfunctions	No

	Transport via Ship from Dedicated Terminal	Technically Feasible	Economically Feasible	Environmental effects relate primarily to Local Economy, Land and Resource Use; shipping related effects are similar in both scenarios.	Yes
	Truck Transport to an Existing Terminal Followed by Transport via Ship (e.g., Auld's Cove)	Technically Feasible	Not Economically Feasible due to truck transportation costs, which would eliminate profitability	Significantly more environmental and economic impacts due to truck traffic through rural and residential areas. Increased air and noise emissions in this scenario.	No
Marine Terminal Location	Eastern Location	Technically Feasible	Economically Feasible	Environmental effects are similar under both alternatives. The VCs Marine Species and Habitat and Commercial Fisheries and Aquaculture would be affected in a similar manner at both terminal locations.	Yes
	Western Location	Not Technically Feasible due to shallow water depths	Economically Feasible	As above; this location is also slightly more sheltered from winds originating to the northeast.	No
Marine Terminal Construction	Rubble Mound Wharf	Technically Feasible and permits the secure storage of acid generating rock; more operationally efficient since it permits vehicular access to ship mooring points for maintenance	Economically Feasible; less expensive to design, build and maintain	Both approaches would affect Marine Species/Habitat and Commercial Fisheries to approximately the same degree. Rubble Mound Wharf occupies more seafloor than the Concrete Caisson Wharf but the rubble would eventually act as lobster habitat.	Yes
	Concrete Caisson Wharf	Technically Feasible but less stable in severe weather; more dangerous to maintain since boat access would be needed.	Economically Feasible	Concrete Caisson Wharf occupies less seafloor than the Rubble Mound Wharf but would shade the seafloor, negatively affecting habitat quality and use.	No
Stockpile Locations	Western End Opposite the Marine Terminal	Technically Feasible	Economically Feasible: this location is both operationally and	In both alternatives, several wetlands would be lost. This alternative provides effective noise and visual mitigation.	Yes

			economically more practical.		
	Eastern End near Wetland 2	Technically Feasible although it greatly increases the complexity of operation and may introduce occupational health and safety risks	Not Economically Feasible: this location requires a complete reconfiguration of processing plant and a much longer conveyor system to deliver aggregate to the marine terminal.	In addition to wetland loss, Wetland 2 is potentially exposed to runoff from the stockpiles in this alternative	No
	Collection tank for septic wastes with transport and treatment at the Canso municipal waste water treatment facility	Technically Feasible and practical	Economically Feasible and cost effective	Minimal impact to Groundwater Resources and Marine and Surface Water Resources.	Yes
	Other septic treatment systems: conventional septic tank and leach field, raised bed systems, rotating biological contactors, peat-based treatment systems, constructed wetlands, and recirculating sand filtration	Not Technically Feasible due to lack of soil cover (conventional leach field): Technically Feasible but poor operational records when applied to operations at this scale (non-conventional treatment systems).	Economically more expensive to design, purchase, operate and maintain	Varying long term impacts can be expected to Groundwater Resources and Marine and Surface Water Resources through treated effluent discharge.	No
Waste Management	"Crusher fines" storage outside of the quarry	Technically Feasible	Economically Feasible but more expensive considering the increased transport distance to the storage site and the greater number of times the materials would be handled	Increased risk of accidental discharge with potential negative effects on Marine and Surface Water Resources, Terrestrial Ecosystems, Habitat & Vegetation, Wetlands, and Terrestrial Wildlife. Similar anticipated effects (i.e., minimal) on Groundwater Resources in both alternatives. Increased handling and transport increases impacts to air quality.	No

	"Crusher fines" storage within the quarry	Technically Feasible	Economically Feasible	No risk of accidental discharge to the environment (potentially affecting Marine and Surface Water Resources, Terrestrial Ecosystems, Habitat & Vegetation, Wetlands, and Terrestrial Wildlife)	Yes
Electrical Supply	Tie-in to the existing electrical transmission line	Technically Feasible	Economically Feasible; more expensive over the short term but costs are recovered over the longer term.	Environmental effects associated with habitat and vegetation loss within the right of way are minimized by using the same right of way for the access road.	Yes
	Use of multiple on-site generators	Technically Feasible	Economically Feasible but more expensive over the long term due to fuel, lubricant and transport costs, as well as maintenance and operating costs	Increased risks of fire and fuel spills given the generators' fuel requirements; increased impacts to ambient noise levels; increased GHG emissions	No

5.0 ENVIRONMENTAL EFFECTS ASSESSMENT METHODOLOGY

To establish the appropriate scope of an environmental assessment, it is standard practice to limit the assessment to those environmental components that are valued or of interest for ecological, scientific, cultural, regulatory and/or economic reasons. In keeping with the terminology used in the federal EIS Guidelines issued for the Black Point Quarry Project, these aspects are referred to as Valued Components (VCs). As described below, identification of the specific VCs considers feedback from the public, regulatory agencies, First Nations communities and other stakeholders. The EIS Guidelines (CEA Agency 2014) issued for the Black Point Quarry Project describe the type of Project information required, the scope of the environmental assessment and the factors to be considered during the assessment.

5.1 Overview

The method used to predict the effects of the Black Point Quarry Project was developed to meet the requirements of the EIS Guidelines (CEA Agency 2014). These Guidelines include requirements of both the federal and provincial governments. In addition, the methodology is intended to incorporate:

1. Subjects, concerns and issues raised by the Mi'kmaq, fishermen and the public at large over the course of the project;
2. The environmental and social aspects of interest to the scientific and regulator communities; and
3. Legislative and regulatory requirements that apply to this type of development.

The following sections describe the methodology used to derive:

- The spatial and temporal boundaries of the study areas;
- The origin and scope of the VCs that will be evaluated to assess project impacts;
- The probable interactions between the Project and the VCs;
- The potential environmental effects of the Project on the VCs;
- The mitigation measures that will be used to eliminate, reduce or control the potential environmental effects; and
- The residual effects that remain after mitigation measures are applied, combined with a determination of their significance.

The goal of applying a defined environmental assessment methodology is to carefully examine the Project and related activities to ensure they will not cause “serious or irreversible harm to the environment, especially with respect to environmental functions and integrity, system tolerance and resilience, and/or the human health of current or future generations” (CEA Agency 2014).

5.2 Application of the Precautionary Approach

The joint federal-provincial EIS Guidelines require that the proponent examine the proposed project infrastructure and activities and demonstrate the project has been planned in a “precautionary manner in order to ensure that they would not cause serious or irreversible damage to the environment...” (CEA Agency 2014). To demonstrate the precautionary approach, this environmental assessment:

1. Describes and justifies the assumptions made about the effects of the Project, and the approaches to minimize these effects;
2. Shows that priority will be given to strategies that avoid the creation of adverse effects;
3. Describes contingency plans that explicitly address accidents and malfunctions; and
4. Outlines follow-up and monitoring programs to verify impact predictions.

5.3 Valued Components Selection

The EIS Guidelines define Valued Components (VCs) as “attributes associated with the project that have been identified to be of concern by the proponent, government agencies, Aboriginal peoples and/or the public. The value of a component not only relates to its role in the ecosystem, but also to the value placed on it by humans” (CEA Agency 2014).

An internal issues-scoping exercise was undertaken to identify the VCs of both general and project-specific interest. For the Black Point Quarry Project, provisional VCs (Table 5-1) were identified through:

- Discussions regarding potential environmental concerns with the CEA Agency, DFO, Environment Canada, Transport Canada, NSE and NSDNR;
- A review of the EIS Guidelines prepared for this project, especially those subjects listed in section 9.1 of the Guidelines (CEA Agency 2014);
- A review of applicable provincial and federal regulation, including an appraisal of species of conservation concern and Species at Risk. The Guidelines specifically require consideration of the factors listed in subsection 19(1) of *CEAA 2012*, as well as those presented section 79 of the *Species at Risk Act* (CEA Agency 2014);
- Discussions with government scientific authorities (e.g., hydrogeologists, Species at Risk specialists, wetland experts, etc.);
- Previous environmental studies conducted on site by AMEC, Davis MacIntyre Associates, Mi'kma'ki All Points Services and others;
- Comments raised a public open house meeting held by Morien in Queensport on April 22, 2014 and subsequent comments received as part of the ongoing public consultation process as noted in Section 11;
- Comments raised during face-to-face meetings with nearby residents, fishermen and other stakeholders, including the Mi'kmaq (Section 11);
- A review of information submitted in support of nearby and similar environmental assessments; and
- The professional experience of the Project team.

**Table 5.1:
List of Provisional Valued Components**

Environmental Aspect	Provisional VC
Atmospheric Resources	Air Quality & Climate Change
	Noise
	Ambient Light
Biophysical Resources	Geology, Soil & Sediment
	Groundwater Resources
	Marine and Surface Water Resources
	Terrestrial Ecosystems, Habitat & Vegetation
	Wetlands
	Terrestrial Wildlife
	Freshwater Species and Habitat
	Marine Species and Habitat
	Species at Risk
	Local Economy, Land and Resource Use
Socio Economic and Heritage Resources	Tourism and Recreation
	Commercial Fisheries and Aquaculture
	Archaeological and Heritage Resources
	Aboriginal Land and Resource Use

5.4 Likely Project-Environment Interactions

Most interactions between the Project and the surrounding environment are fairly obvious and can be logically expected once the project activities and infrastructure have been described. In many instances, project-environment interactions are *direct*. For example, the quarry will remove granite rock from beneath certain existing wetlands: these wetlands will inevitably be lost. Other interactions may be *indirect* and are less obvious. For example, if down slope wetlands outside the property boundary are fed by surface runoff falling on the granite, then removal of the granite rock may reduce runoff and so negatively affect these wetlands.

In order to determine the potential direct and indirect interactions, the Project team (a) reviewed the anticipated activities required to construct, operate and decommission the Project; (b) considered the potential direct and indirect effects from these activities, (c) identified likely pathways between the Project and the receiving environment, and (d) assessed the probable Project effects on the environment through these pathways.

A “pathway” is a link between a Project activity and the environment. It is the means or route through which the Project may positively or negatively affect one or more environmental and/or social receptors. On occasion, a VC can act as both a receptor and a pathway. For example, surface water (the receptor) may be affected by the Project if erosion is not properly controlled during construction. At the same time, surface water may act as a pathway if poor surface water quality negatively affects aquatic organisms that depend on that water.

This linkage between the source, the pathway and the receptor is the core of the environmental assessment process. Once the linkage has been established, the assessment process can

predict the magnitude and duration of impacts, then evaluate mitigation measures to limit or eliminate those impacts. These steps are described in detail for each VC in Section 7.0.

Potential Project interactions with the provisional VCs are presented in Table 5-2. Table 5-3 summarizes the rationale for the selection of each VC, and also includes a description of the potential for certain VCs to act as pathways as well as receptors.

Table 5.2:
Potential Project Interactions with Valued Components (VCs)

Project Activity	Geology, Soils and Sediment	Groundwater Resources	Surface Water Resources	Climate Change	Air Quality	Noise	Ambient Light	Terrestrial Habitat and Vegetation	Wetlands	Terrestrial Fauna	Migratory Birds	Freshwater Species and Habitat	Marine Water Quality	Marine Species and Habitat	Species at Risk	Economy, Land & Resources	Commercial Fisheries and Aquaculture	Marine Safety and Navigation	Visual Landscape	Tourism and Recreation	Aboriginal Lands and Resource Use	Archaeological Resources

**Table 5.3:
Basis for Selection of VCs**

		Relevance to Environmental Features										Rationale for VC Selection (Interactions, Pathways and Relevance)
Environmental Category	Valued Component (VC)	Project - Environment Interaction (D=Direct; P = as Pathway)	Legal Requirement	Scientific Interest	Biophysical Context	Socio Economic	Human Health	Enjoyment of Life and Property	Cultural	Agency or Public Concern	Requirement of EIS Guidelines	
Biophysical Environment	Air Quality and Climate Change	D,P	☑	☑		☑	☑		☑	☑		<ul style="list-style-type: none"> • Potential for negative effects to local air quality. • Potential for contributions to local and global climate change. • Pathway to potential impacts on flora, fauna, and human health.
	Noise	D,P	☑	☑		☑	☑		☑	☑		<ul style="list-style-type: none"> • Potential for changes to existing acoustic environment. • Potential pathway for impacts on fauna and human health.
	Ambient Light	D, P						☑		☑	☑	<ul style="list-style-type: none"> • Potential for changes in the existing lighting conditions. • Potential pathway for impacts on fauna and human health.
	Geology, Soil & Sediment Quality	D, P			☑	☑				☑	☑	<ul style="list-style-type: none"> • Potential for generation of acid drainage from Halifax Formation bedrock. • Pathway to potential impacts on flora, fauna, and human health.
	Groundwater Resources	D,P	☑	☑	☑		☑			☑	☑	<ul style="list-style-type: none"> • Potential for negative effects on groundwater quality and quantity. • Potential for impacts on local water supply wells. • Pathway to potential impacts on human health.
	Marine and Surface Water Resources	D,P	☑	☑	☑		☑			☑	☑	<ul style="list-style-type: none"> • Potential marine water quality effects from acid generating rock, erosion during construction phase, stormwater discharges, accidental spills, and wastewater discharges. • Potential for siltation from erosion and stormwater discharges. • Pathway to potential impacts on fauna and human enjoyment of resources.
	Terrestrial Species	D,P	☑	☑	☑					☑	☑	<ul style="list-style-type: none"> • Potential for terrestrial habitat removal and/or alteration.

	and Habitat, including SAR											<ul style="list-style-type: none">• Potential for adverse effects on species resulting from changes in terrestrial habitat.• Potential for adverse effects on SAR as a result of direct impact or habitat changes.• Pathway to potential impacts on traditional land uses/ resource uses.
	Freshwater Species and Habitat, including SAR	P		☑	☑	☑			☑			<ul style="list-style-type: none">• Pathway to potential impacts on Aboriginal, commercial, recreational fisheries.
	Marine Species and Habitat, including SAR	D,P			☑	☑			☑	☑		<ul style="list-style-type: none">• Potential for 'severe harm' effect to fisheries productivity.• Potential for adverse effects on marine SAR as a result of direct impact or 'severe harm'.• Pathway to potential impacts on Aboriginal, commercial, recreational fisheries and Human Health.
	Wetlands	D, P		☑	☑	☑			☑	☑		<ul style="list-style-type: none">• Potential for direct loss and/or adverse effects on wetland extent and functions.
Socio-Economic and Cultural Environment	Local Economy, Land and Resource Use	D				☑	☑		☑	☑	☑	<ul style="list-style-type: none">• Short term employment opportunities during construction.• Long-term employment opportunities during operation.• Economic spin-off effects.• Potential to positively or negatively affect real estate values• Contributions to municipal tax base.• Pathway to potential impacts on traditional land uses/ resource uses.
	Tourism and Recreation	D				☑			☑	☑	☑	<ul style="list-style-type: none">• Potential to negatively affect wilderness/nature oriented tourism.• Improved economics leading to improvement of tourism infrastructure
	Commercial Fisheries and Aquaculture	D		☑	☑	☑	☑	☑	☑	☑	☑	<ul style="list-style-type: none">• Potential for displacement of fishermen to less productive areas• Potential for increased competition / lower harvests due to displacement• Potentially reduced harvest rates/ sales volumes as a consequence of adverse effects on resource.
	Aboriginal Land and Resource Use	D		☑			☑		☑	☑	☑	<ul style="list-style-type: none">• Potential for conflict with traditional land uses and land claims.
	Archaeological & Heritage Resources	D		☑					☑	☑	☑	<ul style="list-style-type: none">• Potential for disturbance of archaeological sites.

5.5 Project Boundaries

An important aspect of an environmental assessment is determining assessment boundaries that define the extent of anticipated effects. Project effects can be felt over different time periods (temporal boundaries), in different geographic areas (spatial boundaries) or can be limited by the nature of the effect (administrative and technical boundaries). Boundaries help focus the scope of the assessment to those zones that will logically experience actual project impacts.

5.5.1 Temporal Boundaries

Temporal boundaries represent the duration over which the Project activities interact with each VC. Since this may change depending on the VC, the duration of these interactions is described in each individual VC chapter. In general, the temporal boundaries are (a) the construction period, and (b) the operating life of the Project, through to decommissioning and reclamation.

Overall project timelines are based on an expectation of approximately two years to obtain regulatory approval before Project construction. This period allows sufficient time to achieve release from the environmental assessment process, which is followed by detailed project design and applications for construction and operating permits.

Initial processing plant construction is expected to require two to three years. As noted, the Proponent expects to begin with a smaller processing plant and expand operations as market conditions warrant. Construction on the marine terminal is expected to require approximately 11-13 months.

At this time, the expected operating life of the quarry is at least 50 years. Progressive reclamation will occur over the lifetime of the project, to extent this activity is possible within the active quarry. Closure, decommissioning, and final reclamation would follow the operating phase as is expected to require about two years.

5.5.2 Spatial Boundaries

Spatial boundaries are those geographic limits that help define the scale and range of the interactions between the Project and each VC. The spatial boundaries will also vary in accordance with each VC and so are presented in detail in each VC section. The following spatial boundaries are used for this assessment,

1. The **Project Area** (PA) is confined to all territory within the limits of the Project property boundary (**Figure 1.0-2**);
2. The **Affected Area** (AA) is the area which could potentially be affected by Project components or activities immediately beyond the PA. The Affected Area is similar to the area directly adjacent the Project property but can be larger depending on the component being considered.

The extent to which the AA is within the spatial boundaries of the Project is VC-specific and dependent on biological and physical considerations. For most VCs the AA is generally

within two kilometers of the Project property limit. Affected Area boundaries may be defined, for example, by habitat use of certain species, sub-watershed boundaries, and/or the predicted geographic extent of measureable air and noise emissions;

3. The **Study Area**: the Study Area (SA) is defined by considering all Project-environment interactions, including diffuse or longer range effects such as noise and light, which can only be modeled at this time. It may include, for example, the waters of Chedabucto Bay south of the shipping lanes where the Project-related marine activities and interactions will occur; for other VCs the SA may include the MODG where the majority of the social and economic effects can be expected.

Table 5-4 shows the spatial boundaries used to collect data during the baseline assessment phase of the environmental assessment, which in turn is applied to the effects assessment for each VC.

**Table 5.4:
Spatial Boundary Assessment by Valued Component**

Environment	Valued Component (VC)	Project Footprint	Adjacent Lands	Chedabucto Bay	MODG	Nova Scotia	Comment
Biophysical Environment	Air Quality and Climate Change	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>			<input checked="" type="checkbox"/>	NS is addressed with respect to climate change; air quality is of local interest.
	Noise	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>				AA is defined by the distance at which excessive noise effects are predicted.
	Ambient Light	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>			AA is defined by the distance at which light trespass is predicted.
	Geology, Soil & Sediment Quality	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>			Chedabucto Bay is included within AA.
	Groundwater Resources	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>				AA extends to the limit of the groundwater drawdown cone at full quarry buildout.
	Marine and Surface Water Resources	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>			Affected marine waters include those that may be affected through accidental or treated water discharges as well as Chedabucto Bay between the shore and shipping lanes transited by Project related vessels. Affected surface waters are defined through hydrological connectivity to the Project site.
	Terrestrial Species and Habitat, including SAR	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>				AA is defined by sub-watershed boundaries, habitat range and ecological links as well as by the geographic extent of predicted noise & air quality effects; marine areas for this VC are addressed in relation to waterfowl, wintering birds, and marine birds.
	Freshwater Species and Habitat,	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>				Sub-watershed boundaries are used to define AA
	Marine Species and Habitat, including SAR				<input checked="" type="checkbox"/>		AA is the marine terminal and vicinity and Chedabucto Bay between the shore and shipping lanes transited by Project related vessels.
	Wetlands	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>				AA is defined through hydrological connectivity to the Project site.
Socio-Economic and Cultural Environment	Local Economy, Land and Resource Use	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	AA is generally taken as Half Island Cove, Upper Fox Island and Fox Island Main; PA is the MODG
	Tourism and Recreation	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		AA is generally taken as extending from Half Island Cove to Fox Island Main.

Commercial Fisheries and Aquaculture	<input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/>	PA includes the zoned fished by local fishermen who generally reside from Guysborough to Canso but may include fishermen from outside this area
Aboriginal Land and Resource Use	<input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> <input checked="" type="checkbox"/>	. AA includes all areas that could be affected by the Project (e.g., through noise, light, dust etc) and are potentially used by Aboriginal peoples for traditional purposes. Spatial boundaries are defined in relation to health and socio-economic conditions for Aboriginal peoples
Archaeological & Heritage Resources	<input checked="" type="checkbox"/>	PA is confined to those areas disturbed by the Project

SAR = Species at Risk; MODG = Municipality of the District of Guysborough

5.5.3 Technical Boundaries

Technical boundaries represent limits to the Project team's ability to assess a VC, pathway or receptor. A technical boundary is a theoretical or actual limitation on the ability to measure, assess, and/or monitor potential environmental effects. These data gaps may in turn limit the ability to predict the potential effects of the Project on a particular VC. The EA methodology requires that these data gaps, if present, be described along with the steps taken to address the gaps (CEA Agency 2014).

5.5.4 Administrative Boundaries

Administrative boundaries are those limits that originate through regulatory, public policy or economic reasons. Administrative boundaries include, for example, the regulatory requirements as described in Section 2.0, the physical boundaries of wildlife sanctuaries, the different NAFO Division and Unit (fishing) Areas, and the temporal boundaries of hunting, fishing or trapping seasons. Where applicable, administrative boundaries are described in each VC chapter (Section 7.0)

5.6 Impact Prediction

Ultimately, an environmental assessment aims to determine whether a given project is "likely to cause significant adverse environmental effects"; these terms are defined in the reference CEA Agency (1994). As noted above, the environmental effects assessment consists of a series of steps beginning with the identification of the VCs. Following identification, the "baseline" or existing condition of each VC type is studied and described. Once the existing condition for each VC is known, the environmental assessment:

1. Predicts the adverse Project-related environmental effects or impacts and evaluates the scope and scale of these effects;
2. Describes a number of mitigation measures and practices that the Proponent will use to avoid, minimize, eliminate, mitigate, or compensate for the effects;

3. Predicts residual adverse environmental effects after mitigation but before the assessment of the cumulative effects described below.
4. Assesses the cumulative effects from other probable (i.e., certain and reasonably foreseeable) future projects, taking into consideration past and current projects; and
5. Determines the residual adverse effects remaining after mitigation and assesses the significance of these effects on each VC. This step also includes consideration of the cumulative effects described above.

5.7 Environmental Effects Assessment

As noted, the manner in which a project may affect the VCs is a function of the linkage or pathway from one to the other. The environmental effects of a project are a function of its activities, while the pathways are a function of several things, including project activities, ecological systems, and contaminant properties. Typically, the assessment uses provincial and federal guidelines and policies to determine potential pathways and effects, combined with computer or numerical modeling, knowledge of the site conditions and professional judgment. Other information sources include input from experts, stakeholders, and regulators; experience from previous environmental assessments; primary scientific literature.

5.8 Mitigation and Residual Effects

The next step in the environmental assessment determines the potential residual adverse environmental effects by Project phase. Residual adverse effects are derived using a three-step process:

1. Determine the potential interactions between the VCs and Project activities, for each Project phase, and the environmental effects of these interactions in combination with those from other likely future projects;
2. Assess the effect of the mitigation strategies applicable to each of the interactions; and
3. Characterize the nature and extent of the remaining, residual environmental effects after mitigation measures have been applied. That is, determine their “significance” and “likelihood”.

Environmental effects assessment matrices have been used to summarize the analysis of environmental effects (see Table 5-5 for an example). Cumulative environmental effects and potential impacts occurring from accidents, malfunctions and unplanned events are described in separate sections. This allows for a comprehensive analysis of all Project-VC interactions. Supporting discussion in the accompanying text highlights particularly important relationships, site data and assessment results.

A great variety of mitigation measures are available for most projects. These measures range from the use of standard industry best management practices for construction and operation, through training and sensitization of site workers, to site-specific design features that can be applied to limit or eliminate a particular effect. Based on the Proponent’s extensive experience with the potential environmental effects of aggregate production, a number of mitigation

measures were incorporated into the Project design and implementation plan in order to minimize potential adverse effects. In addition, mitigation measures can include environmental protection strategies, environmental management systems, and compensation projects, as noted in the EIS Guidelines, mitigation measures must be technically and economically feasible. Mitigation measures are described in each VC assessment chapter of Section 7.0.

Table 5.5:
Residual Environmental Effects Assessment Matrix for [Name of VC]

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Construction									
Activity 1									
Activity 2									
Operation									
Activity 1									
Activity 2									
Decommissioning									
Activity 1									
Activity 2									
Legend <u>Magnitude (see Table 5.6):</u> U= Unknown 0 = Nil 1 = Low 2 = Medium 3 = High variation)									
<u>Geographic Extent:</u> 1 = < 1 km ² 2 = 1 – 10 km ² 3 = 11 – 100 km ² 4 = 101 – 1,000 km ² 5 = 1,001 – 10,000 km ² <u>Duration:</u> 1 = < 1 month 2 = 1 – 12 months 3 = 13 – 36 months 4 = 37 – 72 months 5 = > 72 months									
<u>Frequency:</u> 1 = < 11 events/year 2 = 11 – 50 events/year 3 = 51 – 100 events/year 4 = 101 – 200 events/year 5 = > 200 events/year 6 = continuous <u>Reversibility:</u> R = Reversible I = Irreversible									
<u>Ecological / Socio-Economic Context:</u> 1 = Relatively pristine area or area not adversely affected by human activity. 2 = Evidence of adverse environmental effects. N/A = Not applicable A = Adverse P = Positive									

The legend is typical for biological VCs and is provided for illustrative purposes only. The legend may vary from VC to VC as appropriate.

The prediction of residual effects follows three general steps (CEA Agency 1994):

- Determining whether the environmental effects are *adverse*;
- Determining whether the adverse environmental effects are *significant*; and
- Determining whether the significant adverse environmental effects are *likely* to occur.

Some of the key factors that must be considered in determining *adverse* environmental effects are given in the CEA Agency's guidance document (CEA Agency 1994). This guidance was used when applying Table 5.5 to each VC:

- Negative environmental effects on the health of biota;
- Loss of rare or endangered species;
- Reduced biological diversity;
- Loss or avoidance of critical / productive habitat;
- Habitat fragmentation or interruption of movement corridors and migration routes;
- Transformation of natural landscapes;
- Chemical discharge;
- Loss or detrimental change in current use of lands and resources for traditional purposes;
- Foreclosure of future resource use or production;
- Adverse environmental effects on human health or well-being;

5.9 Residual Effects and the Determination of Significance

Residual impacts are those environmental effects predicted to remain after the mitigation measures have been applied or implemented. The predicted residual effects are considered for each Project phase (construction, operation, and decommissioning) and for potential accidental events. The *significance* of these residual effects to the local and regional areas is evaluated by assessing those criteria outlined in guidance documents provided by the CEA Agency (1994):

- **Magnitude:** the amount or degree of change in a measurable parameter or variable relative to existing conditions. It refers to the severity of the adverse environmental effect after mitigation.
- **Geographic Extent:** the area over which the adverse effect is predicted to occur after mitigation.
- **Duration:** the period of time over which the adverse effect will occur following mitigation.
- **Frequency:** the number of times during the Project that an effect might occur (e.g., one time or multiple times).
- **Reversibility:** the likelihood that a VC will recover from an adverse environmental effect, including consideration of reclamation, restoration, compensation and offset programs. Reversibility is considered on a population level for biological VCs: while

a severe effect like mortality is irreversible at the individual level, the environmental effect on the population may be reversible.

- **Ecological or Social Context:** the general setting of the area where the Project is located, as indicated by existing levels of human activity and associated disturbance.

The magnitude or severity of an adverse Project effect can be difficult to ascertain in some cases. To help assess magnitude, a relative rating was used, based on that used for other recent projects in the area (Table 5-6).

With respect to geographic extent, frequency, and duration, the environmental assessment employed defined or absolute values for these parameters, as described in each VC section.

**Table 5.6:
Definitions for Levels of Magnitude**

Rating	Magnitude*
High	An environmental effect affecting a whole ecological population or group of people, or where the effect or parameter is outside the range of natural variability determined from local knowledge over many seasons.
Medium	An environmental effect affecting part of a population, or one or two generations, or where there are rapid and unpredictable changes in an effect or parameter so that it is temporarily outside the range of natural variability determined from local knowledge over many seasons.
Low	An environmental effect affecting a specific group of individuals in a population in a localized area, one generation or less, or where there are distinguishable changes in a specific parameter; however, the parameter is within the range of natural variability determined from local knowledge over many seasons.
Nil	No environmental effect.
Unknown	An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.

(source: modified from AMEC 2013).

*Note: Definitions for magnitude for air and water quality are specific and addressed separately in their respective chapters in Section 7.0.

To determine the likelihood of significant adverse residual effects, the assessment considers *probability* of occurrence and the *scientific uncertainty* regarding the information used in the impact assessment.

5.10 Cumulative Environmental Effects

Cumulative environmental effects are residual project effects combined with the environmental effects of future projects and/or activities.

For the Black Point environmental assessment, the descriptions of the existing environment and of the current condition of each VC already includes the effects other past and current projects occurring within the Project Area. The assessment assumes that these existing projects will continue in the future and will have similar effects as are currently observed. The assessment has, therefore, integrated the cumulative effects of these ongoing projects and activities.

The cumulative effects assessment presented in Section 9.0 thus focuses on the effects of future projects and activities. This is consistent with guidance documentation developed by the CEA Agency: “temporal boundaries...should take into account future physical activities that are certain and reasonably foreseeable, and the degree to which the environmental effects of these physical activities will overlap those predicted from the designated project” (CEAA 2013).

5.11 Follow Up and Monitoring

“Follow-up” is a process that verifies the accuracy of the predicted impacts and determines the effectiveness of the measures taken to mitigate the adverse environmental effects.

A series of follow-up programs will be developed for the Black Point Quarry Project; these programs are outlined in Section 10. The elements of the programs will be developed through consideration of each VC, and where appropriate or warranted, follow-up measures will be taken.

In addition to follow-up programs pursuant to requirements of *CEAA 2012*, the Proponent will also evaluate the need for monitoring required to ensure regulatory or corporate compliance, and commitments to third parties. To help achieve the goal cause of preventing “serious or irreversible harm to the environment” as required by the EIS Guidelines (CEA Agency 2014), the proponent will implement environmental management and contingency plans to prevent or address situations during construction, operations and decommissioning that may result in accidents or malfunctions and lead to unexpected effects.

5.12 Effects of the Environment on the Project

The effects of the environment on the Project (i.e., severe weather, earthquakes, etc.) have also been taken into consideration. Project activities and infrastructure were reviewed for interactions with the natural environment, including wind, waves, ice and extreme precipitation events. Project plans and activities have been designed to reflect the limitations imposed by the natural environment. A significant effect of the environment on the Project is one that:

- Harms Project personnel or the public;
- Results in a substantial delay in construction (e.g., more than one season) or shutdown of operations;
- Damages infrastructure and compromises public safety; and
- Damages infrastructure to the extent that repair is not economically or technically feasible.

The effects of the environment on the Project are assessed in Section 8.0. Where effects of the environment on the Project can in turn result in effects to the environment (e.g., an oil spill could result from weather or ice conditions), this is addressed in the environmental assessment for each of the VCs. In the case of an accidental event, the worst case scenario event, regardless of the cause, has been assessed for each VC (Section 7.18).

5.13 Description of the Retained VCs

Tables 5.2 and 5.3 demonstrate that the provisional VCs identified in the scoping exercise can be potentially affected by the Project through a variety of pathways. This section describes the nature of each VC in more detail and provides a rationale for its selection.

Air Quality and Climate Change

Air quality concerns associated with the generation of dust have been raised by community residents and the Mi'kmaq, and so Air Quality is identified as a VC. Air quality within the Project site is regulated by the province through the *Workplace Health and Safety Regulations*, which establishes the air quality conditions needed to maintain worker health. Air quality is also a pathway to food chain via the transport of dust and deposition of contaminants on vegetation and surface water. Air quality outside of the Project site is also regulated by the province, which sets air quality emissions standards for industrial operations. Greenhouse gas (GHG) emissions are associated with climate change and have been the subject of provincial regulation and policy initiatives. Vehicles used at the Project site will produce GHGs from the combustion of fuel.

Noise

Activities such as blasting and aggregate processing will undoubtedly produce noise and have the potential to alter the ambient noise conditions of the local area. Noise concerns have been raised by residents living to the east and west of the Property. Changes to ambient noise may also affect a variety of wildlife, migratory birds and SAR. Noise associated with quarry activities is regulated by the province.

Construction of the marine terminal will likely result in temporary increases to noise in the marine environment, which in turn may affect nearby marine biota. Noise may alter the behaviour patterns of certain marine species, which may in turn affect these species at different times of their life cycles. Shipping associated with the marine terminal will add to the noise already present in the marine environment.

Ambient Light

Since the Project site is currently undeveloped, night time ambient light conditions are low. As the site is developed into a quarry, artificial light will be introduced in the form of vehicle headlights, work area illumination, and lights installed on the marine terminal to ensure safe navigation. Changes to ambient light conditions have the potential to negatively affect wildlife in the immediate area and birds from further afield. Increases in night time light levels may also be perceived as a nuisance by local residents.

Bedrock Geology and Sediment

The Project site is currently undeveloped, although historical records suggest at least three families inhabited areas near the coast in the past. Despite this, there is no evidence to suggest that contaminated soils or sediment are present on the site. Bedrock geology and sediment was selected as a VC primarily due to the presence of Halifax Formation rocks which underlay a small portion of the site near the coast. The rocks have the potential to generate acid runoff

when excavated and exposed to oxygen. Excavation of these rocks will be required in preparation for the installation of the processing plant and aggregate stockpiles.

Sedimentation in the marine environment has been identified by fishermen and nearby coastal residents as a potential concern, since the discharge or runoff of sediment-laden water during construction and operation may have harmful effects on nearby lobster habitat. In addition, residents and fishermen have expressed concern regarding the transport of suspended sediment along the shore and into neighbouring bays.

Groundwater Resources

Groundwater extracted from dug and drilled wells is used for drinking water by the nearest residents living to the east, west and south of the Project. In addition, groundwater can play an important role in sustaining streams and wetlands and the habitats and wildlife that depend on them. The Project will remove granite from below the water table, which in turn will affect the local groundwater table. Project activities are perceived by nearby residents to have the potential to affect groundwater supply and quality within their wells. Groundwater is also a potential pathway that can transport contaminants offsite. Groundwater quality is regulated by the province.

Marine and Surface Water Resources

As noted previously, marine water quality may be negatively affected by sediment laden water in the form of discharge or stormwater runoff. Acid rock drainage generated from the disturbance of Halifax Formation rocks may also affect marine water quality. Good quality water is essential to the well being of a large variety of organisms, from the smallest algae to large marine mammals. Marine water quality is also critical to the long term success and sustainability of the commercial fishery, which is a vital economic and social activity in the county and beyond. Marine water quality is regulated by the federal government, which is also responsible for managing and permitting the navigational aspects of the marine terminal.

Surface water quality and quantity play an important role in maintaining ecosystem health in downstream receptors, and surface water can transport contaminants off-site. Surface water can recharge groundwater and thus can act as a pathway for the transport of contaminants to the subsurface in the case of an on-site spill. Surface water is not used for drinking water purposes in the immediate Project area, but the project will use, treat and potentially discharge surface water during the course of operations. In addition, surface water quality may potentially be affected by accidental spills, fires or other events on the property. Surface water quality is regulated by the province.

Terrestrial Ecosystems, Habitat & Vegetation

Terrestrial ecosystems habitat and vegetation express local and regional biodiversity and support ecological resilience. These features form the basis upon which local wildlife populations depend. Terrestrial ecosystems and habitat will be permanently diminished or destroyed, and vegetation will be lost during the course of building and operating the Project. Mi'kmaq has expressed concerns with respect to their continuing ability to harvest terrestrial resources within the Project and adjacent areas, as well as the overall effect of Project activities

on ecological resources in general. Indirect impairments to ecosystems and habitat may occur through Project-related activities such as water use and dust emissions.

Wetlands

Wetlands are highly productive and diverse ecosystems that perform a number of biophysical and ecological functions. They may provide habitat or refuges for a diversity of species, including SAR, attenuate storm flows, recharge groundwater and provide discharge to downstream receptors during dry periods. Over the 50 year life of the Project, development will directly affect a number of wetlands on the Project site, and may indirectly affect others through effects to surface and groundwater flows. These effects will not be felt at once, but rather progressively as the quarry expands over its 50 year production life. Wetlands are regulated by the province.

Terrestrial Wildlife

Terrestrial wildlife species have ecological, aesthetic and recreational importance to the public and First Nations, primarily as a food source and as an economic and recreational resource. Project development will impair or eliminate the productive capacity of some terrestrial habitat within the Project footprint. Other indirect interactions (airborne dust, emissions, noise, vibration, light, water use) may affect species and habitat adjacent to the Project. Most terrestrial species and habitat are regulated by the Province but migratory birds are regulated at the Federal level.

Freshwater Species and Habitat

The creeks and lakes on the Property and in the immediate vicinity support important terrestrial habitat types and a number of aquatic species, but do not contain fish due to their acidity. Nevertheless, freshwater species and habitat are important biological components of larger ecological systems and are valued by the public and the Mi'kmaq. Project activities will destroy small areas of freshwater habitat (and may damage or impair other areas) but the Project will ultimately create considerably more freshwater habitat than currently exists on the site.

Marine Species and Habitat

Marine species and their habitat are valued for the aesthetic, cultural, ecological and economic attributes by First Nations and the public at large. Construction of the marine terminal will permanently destroy sea bottom habitat even as new habitat is created by the terminal foundations. To offset this habitat loss, habitat creation nearby is required by DFO. Transport of aggregate via seagoing vessels will impact upon the marine environment through noise associated with vessel passage and potentially through accidental spills or other incidents at sea. Marine SAR are of interest to scientists, regulators and public due to their inherent biological and cultural value and are protected under federal provincial legislation. Fish and fish habitat in general is regulated by DFO at the federal level.

Species at Risk

Species at Risk are identified as a VC due to their ecological role, scientific value and cultural attributes. Species at Risk may be regulated at the federal level, the provincial levels, or both. The direct loss of habitat used by terrestrial or marine SAR is the primary concern of this VC,

although SAR may be indirectly affected through noise, light and general activity at the Project site.

Local Economy, Land and Resource Use

Economic effects of the Project are of interest to local residents, municipal officials and the provincial government. Nearby residents gain their living through forestry, commercial fishing, tourism, government and service occupations. Project revenues or royalties that flow to the MODG and Project expenditures may positively affect local economies. The Project will also contribute to the municipal tax base. Regional economic improvements can affect the population size and demographics as workers move to the area, purchase property, goods and services, and raise families. Property values can also be affected by large scale project development.

Employment and business opportunities are valued by people who may benefit directly from income generated by the Project and/or indirectly from newly needed services. The Project will require a temporary labour force during construction and a smaller but significant labour force over the long term operation of the Project. In addition to direct hires, the Project will generate employment and economic activity through contracting for goods and services.

Existing and Planned Land Uses

A major development such as the proposed Project can affect existing as well as planned land uses. Current on-site land uses (trapping, local tourism) will be replaced by quarrying and associated activities. Existing and planned land uses on adjacent properties may be impacted through changes to the visual or acoustic environments. Land use is regulated by the Province and through municipal zoning and land use bylaws.

Tourism and Recreation

Residents and tourists alike make use of the local terrestrial and marine resources for outdoor activities such as camping, hiking, fishing, boating, off-road motoring, and hunting. These activities are popular and to a certain degree, available, due to the largely undeveloped nature of the area. The presence of quarry may influence perceptions regarding noise and changes in the visual character of the coastal landscape, resulting in changes to recreational resource use patterns. The Project may result in restrictions to currently accessible beaches and headlands at the Project site. Navigability of water courses and coastal waters is regulated by federal legislation.

Commercial Fisheries and Aquaculture

Marine commercial fisheries represent an important, sustainable resource of historical, cultural, social and economic value to local communities and the Mi'kmaq. As noted, there are no freshwater commercial or recreational fisheries on the Property. Aquaculture is not currently practiced along the south shore of Chedabucto Bay.

The marine terminal will result in limitations to lobster harvesting in the immediate area of the marine terminal and, as result, displacement of those who currently fish in the nearshore at the Black Point site into other areas. The transit of empty and loaded aggregate transport ships has

the potential to interfere with other commercial fishing activities that occur in deeper water between the shipping lanes and the south shore of Chedabucto Bay.

Accidental spills or discharges to the aquatic environment can alter water quality and physical habitat, which in turn can affect life-cycle stages of commercially important species and their food supply.

Fish harvesting is regulated by the Federal Government under the *Fisheries Act*.

Archaeological and Heritage Resources

Post-European contact heritage resources are found on the property near the coast where historical homesteads were established over the course of several generations. Archaeological and Heritage Resources were identified in the EIS Guidelines as a potential VC and concerns have been raised regarding the possible existence of these resources during the public outreach phase of the environmental assessment. Although a 30 m buffer zone will be left undisturbed along the coastline to protect some of these finds, much of the coastal zone inside this buffer will be built upon, thus disturbing, destroying or covering over some of these resources. Archaeological and Heritage Resources are protected through provincial legislation.

Aboriginal Land and Resource Use

Aboriginal culture in the form of traditional land and resource use is practiced on a regular basis by the Mi'kmaq community. Traditional hunting, fishing, and plant harvesting practices are deeply rooted and highly valued in these communities. Mi'kmaq land and resource use could be affected by the Project through the loss of access to or alteration of harvesting areas and traditionally use lands. Overarching Mi'kmaq land claims can affect the establishment of clear title to land designated for industrial development. Legal jurisprudence has defined federal and provincial responsibilities with respect to Aboriginal peoples and the settlement of outstanding land claims. Consideration of Aboriginal interests is legislated by federal and provincial laws and listed in the EIS Guidelines issued for this Project.

6.0 EXISTING CONDITIONS

6.1 Geophysical Environment

6.1.1 *Physiography, Geomorphology and Topography*

The Project site falls within the Atlantic Coast Ecoregion (**Figure 6.1-1**), which is located along the southeastern coast of Nova Scotia (Webb and Marshall 1999). There are eight ecoregions in Nova Scotia; all are subdivisions of the Atlantic Maritime Ecozone. Ecoregions are characterized by distinctive large-order landforms or assemblages of regional landforms, small order climates, water, soils, vegetation, and regional human activity uses and patterns (Neily *et al.* 2003).

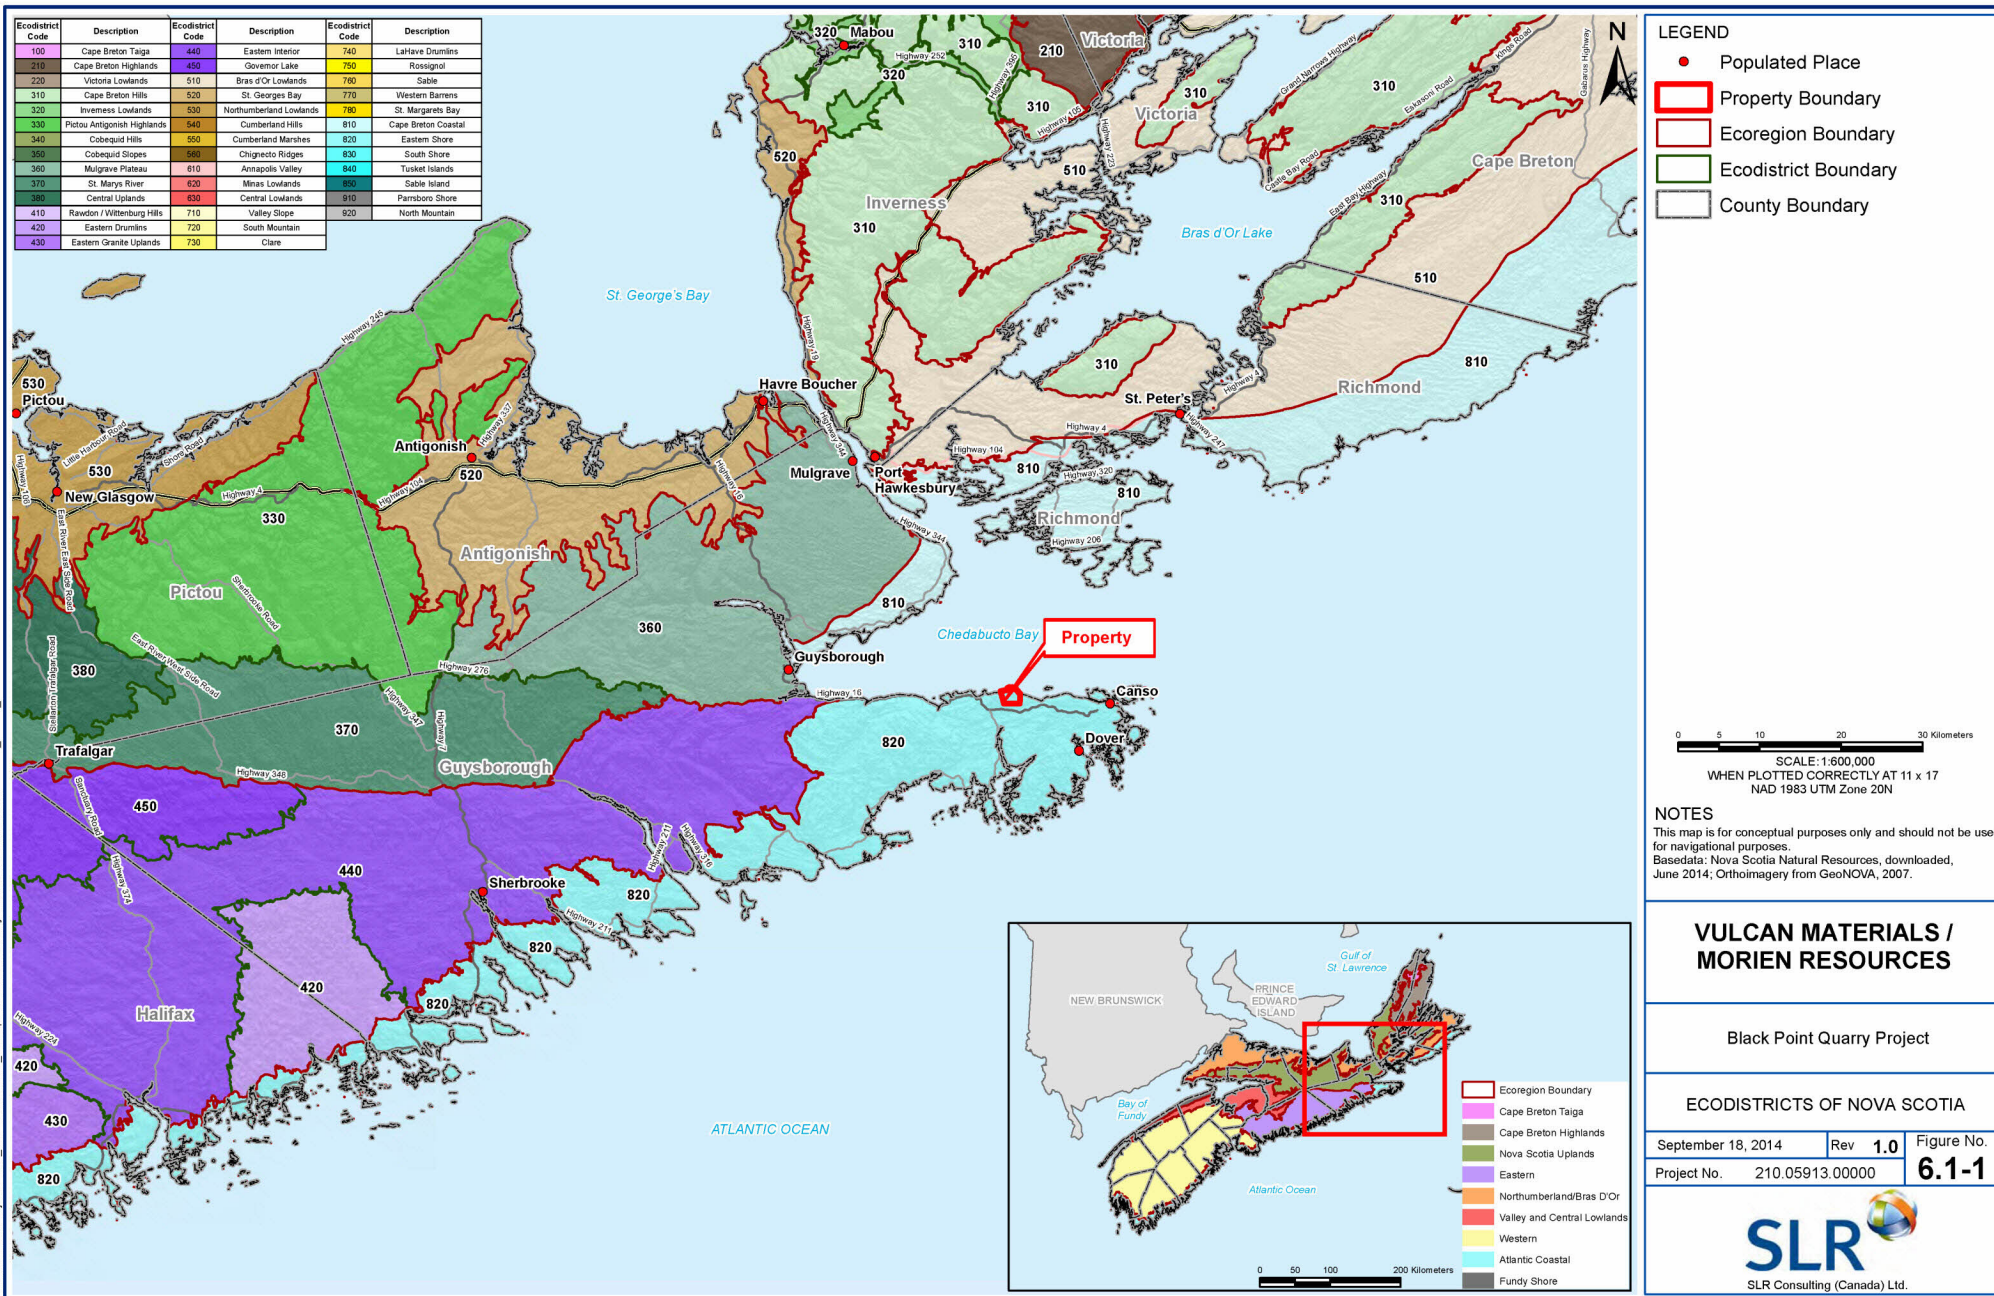

The Atlantic Coast Ecoregion has a highly irregular shoreline. Inactive geological fault lines have had a strong influence on shaping the many deep inlets along the eastern shore of Nova Scotia but these predominantly northwest-trending faults are less common along the south shore of Chedabucto Bay where the coast is less embayed. The south shore of Chedabucto Bay is very linear with an east-west orientation that reflects the presence of the inactive Cobequid-Chedabucto Fault (see 6.1.4). The landforms are underlain predominantly by Paleozoic-age metamorphic and granite bedrock, which is covered by a discontinuous veneer of stony glacial till¹. Common tree species in this Ecoregion include white spruce (*Picea galuca*), black spruce (*Picea mariana*), and balsam fir (*Abies balsamea*). Other tree species include the hardwoods red maple (*Acer rubrum*) and yellow birch (*Betula alleghaniensis*). Common wetlands in this ecoregion include fens, salt marshes, and raised and flat bogs (Webb and Marshall 1999).

Ecoregions are further divided into ecodistricts, which are characterized by distinctive groups of landforms, relief, bedrock and surficial geological material, soil, vegetation, water bodies, and land uses (Webb and Marshall 1999). The Project site is located within the Eastern Shore Ecodistrict. This Ecodistrict spans a varied landscape of landforms, geology, and soils between the east side of the Halifax peninsula up to and including the Canso peninsula. The influence of the Atlantic Ocean provides a consistent coastal climate which is reflected in the forest types found within the Ecodistrict. The Ecodistrict is bounded by granite barrens at both ends, with metamorphosed dark, clay-rich sandstones ("greywackes") and slates of the Halifax and Goldenville formations in between (Neily *et al.* 2003).

The Project site is located on a smooth granite hill with a maximum elevation of approximately 97 m above sea level (asl). This is one of the highest elevations in the region and places the Project site at the top of the local watershed. Topography slopes gently in all directions from the peak of the granite hill; to the north an abrupt change in elevation is observed at 60 m asl. The northwest edge of the property (north of Fogherty Lake) forms a cliff, which descends from 60 m asl to sea level over a distance of about 150 m. This cliff is lower in the north-central and northeast portions of the property between Fogherty Head and Black Point, where the topography levels off at approximately 20-30 m asl and gradually grades to the rocky coast (**Figure 6.1-2**).

¹ Glacial till is a heterogeneous mix of clay, sand, gravel and boulders left behind by melting glaciers.

6.1.2 Soils/Sediment

Approximately 94% of the soils in Guysborough County have developed from glacial till, with the remainder being developed on alluvial (river) deposits or glaciofluvial (rivers of glacial origin) deposits. Textures in the soils developed over till range from sandy loam to loam in the upper layers, while the parent till material ranges from gravelly sandy loam to clay loam. Textures in the alluvial and glaciofluvial soils range from gravelly sandy loam to silt loam in the surface layer, while in the subsoil the material ranges from gravel to silt loam (Hilchey *et al.* 1964).

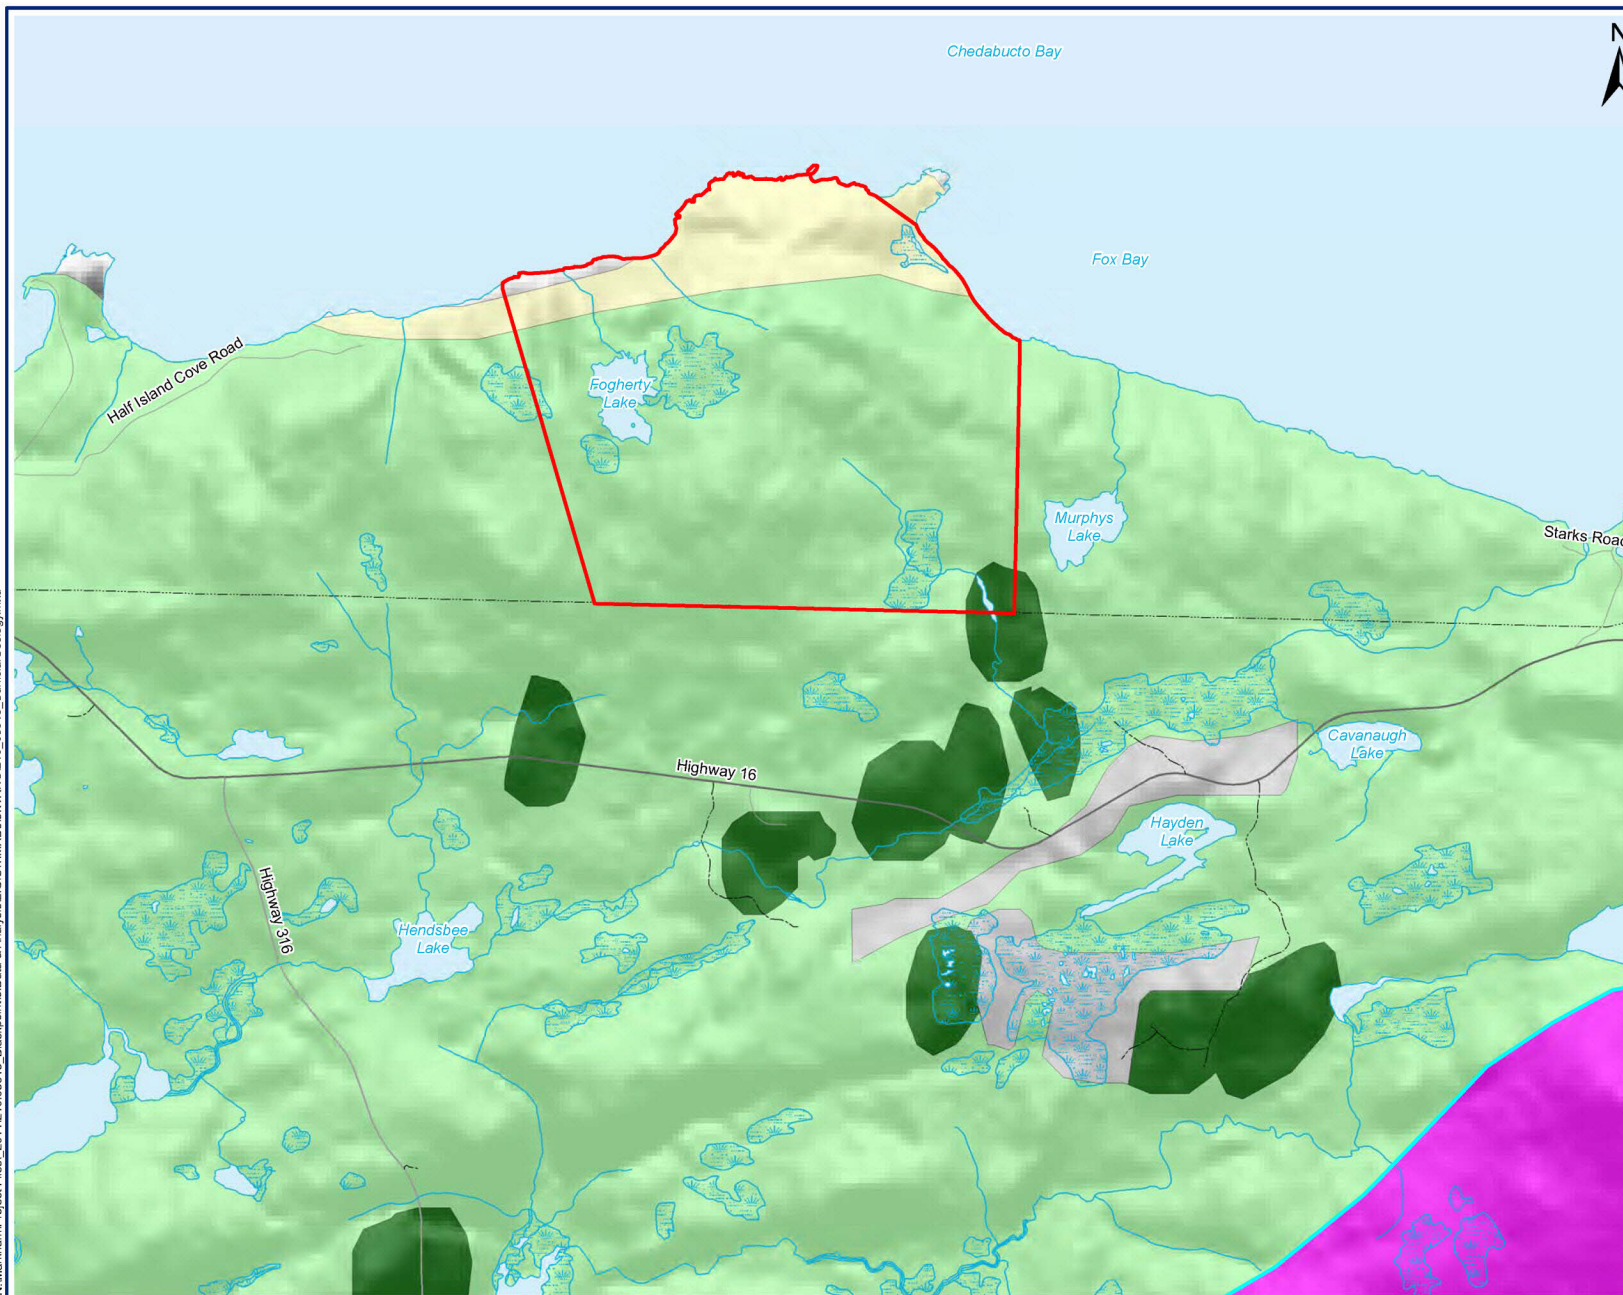

Soils are thin to non-existent on the top of the granite hill that dominates the property. Soils thicken to the east and west at lower elevations where wetlands have developed. The soil map labels the Project site as “Rockland”, defined as soil areas with 50% or more of rock outcrops or boulders (**Figure 6.1-3**). Isolated pockets of peat, defined as brown, poorly decomposed organic material 30 cm or more in depth, are shown adjacent to Fogherty Lake, and form the Castley soil type. A single occurrence of Wolfville Series soil is shown in the extreme southeast corner of the property. This soil consists of “moderately stony, dark brown friable loam over dark grayish brown sandy clay loam”. As noted above, this soil is developed from a parent material made of glacial till, in this case “firm dark reddish brown sandy clay loam glacial till” (SRI 1963).

N:\Marketing\Project Files_2014\210.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\3.WRK\210.05913_SoilCover.mxd

6.1.3 *Surficial Geology*

Surficial geology in the vicinity of the Project site is described on published geology maps (Stea *et al.* 1992; Stea and Fowler 1979) as predominantly comprising Pleistocene-age granite and quartzite tills derived from local bedrock sources (**Figure 6.1-4**). The stony till shown within the property boundary is yellow-brown in color, loose and sandy. Regionally, it averages 2 m thick but is up to 5 m thick in some areas. The quartzite till is bluish-greenish-grey in color, loose and coarser grained than the stony till; it averages 3 m thick but may be up to 20 m thick in some places. A thin band of red till and/or marine deposits developed on Halifax Formation bedrock is present along the coastal portion of the property.

SLR
SLR Consulting (Canada) Ltd.

Observations made on site indicate these tills are essentially absent on the top of the granite hill, but thicken on the slopes of the hill at lower elevations. The tills are well exposed along the coastline at Half Island Cove (Figure 6.1-5) and Fox Island Main. Dug wells, which are used more often than drilled wells in this area to provide potable water, are installed in these loose tills.

Figure 6.1-5:
View of glacial till east of Gaulman Point

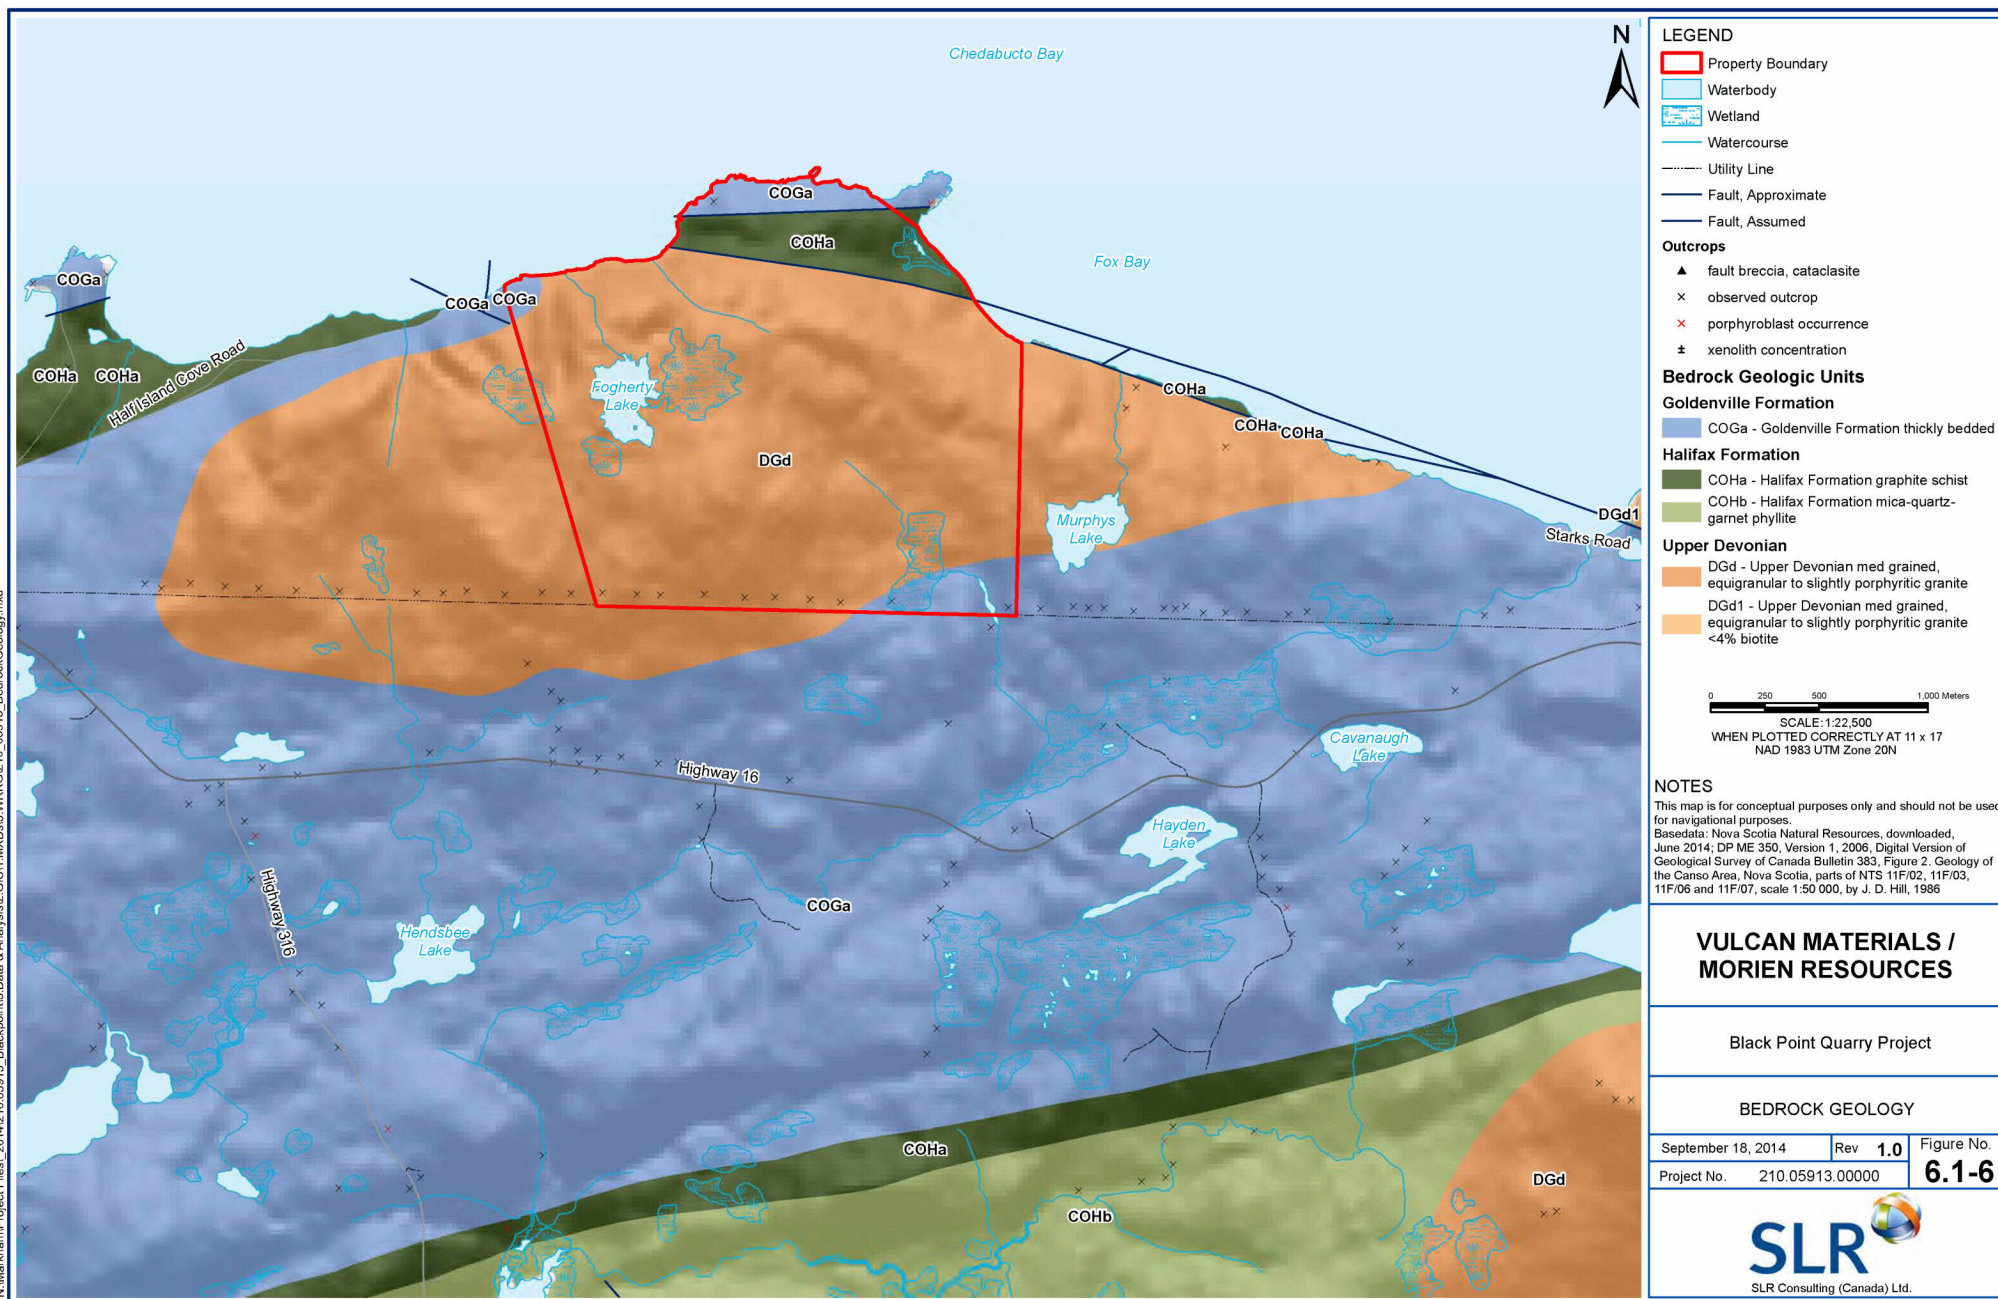

6.1.4 Regional Geology

The Project site is located within the Meguma Terrane, south of the Cobequid-Chedabucto Fault System which separates the Meguma Terrane in the south from the Avalon Terrane in the north. The Meguma Terrane underlies the southern mainland of Nova Scotia, south of a line connecting the Minas Basin with Chedabucto Bay, and also extends seaward. The sedimentary rocks of the Meguma Terrane consist of primarily metamorphosed, fine-grained sandstones and slates with minor amounts of volcanic and carbonate rocks in local areas. The Meguma Terrane was later intruded by younger granitic rocks (NSMNH 1984), including the granite intrusion at Black Point that will provide the aggregate material for the Project.

Granite represents about 20-25% of the bedrock in Nova Scotia and is found throughout mainland Nova Scotia and Cape Breton. The granite intrusions in the Meguma Terrane were generated during the Acadian mountain building event, when the Meguma sedimentary pile was

compressed against, and possibly over, the Avalon Zone (NSMNH 1984). The geology of the site and surrounding area is presented on Figure 6.1-6.

N:\Markham\Project Files_2014\210.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\3 WRK\210_05913_BedrockGeology.mxd

6.1.5 Local Geology

The geology of the Project site and surrounding areas consists of Cambro-Ordovician age metamorphosed sedimentary rocks of the Goldenville and Halifax Formations Figure 6.1-6. The Goldenville Formation is the older of the two and is generally found to the south and west of the Project site, although this rock also outcrops on the tip of the Fogherty Head / Black Point headland. The Goldenville Formation consists of a thickly bedded metamorphosed muddy sandstone (“metawacke”) with minor metamorphosed siltstone and slate (“metapelite”). Immediately to the south of the faulted boundary with the Goldenville Formation on the Fogherty Head / Black Point headland lies the Halifax Formation, consisting of graphite schist (a metamorphosed crystalline rock) interbedded with thin layers of metawacke (Hill 1991).

The majority of the Project site, including the area to be quarried, is underlain by medium-grained granite (Hill 1991). The granite has been intruded into the sedimentary rocks of the Goldenville and Halifax Formations. The granite’s northern boundary with the Halifax Formation is a west-northwest to east-southeast trending fault. Similarly, the boundary between the Halifax and Goldenville Formations between Fogherty Head and Black Point is also a fault. These faults are thought to be part of the Cobequid-Chedabucto Fault Zone that has been inactive for millions of years.

Eleven bore holes have been drilled in the Project site footprint in order to confirm the granite’s suitability as a construction aggregate. The drill logs are provided as an attachment to the Hydrogeological Technical Report in **Appendix A**. The logs describe a pinkish to greyish-white granite comprising 50% to 60% feldspar, 35% to 48% quartz and up to 10% biotite and muscovite mica.

The drill cores indicate that the most frequent fracturing and jointing occurs in the upper 40 m as demonstrated by the fracture frequency plot attached to Hydrogeological Technical Report in **Appendix A**. Two fault zones were noted in the core logs of drill holes BP-8 and BP-9 at 93 to 94 m below ground surface (bgs) and 20 m to 25 m bgs, respectively, and are shown on the fracture plots by fracture frequencies of >20 fractures per metre. Detailed topographic and LiDAR data of the site indicate a bifurcating lineament running from the northwest corner of Murphy’s Lake to Watercourse 2 located northeast of Fogherty Lake. This northwest-southeast trend is consistent with known faulting in the area. Core holes BP-8 and BP-9 are located close to this lineament and potentially intersect a related fault.

Twenty-two granite core samples from three holes drilled during the 2014 resource assessment program were submitted to the laboratory for major and minor element analysis. In total, 49 parameters were measured, including the naturally occurring radioactive elements thorium and uranium. The analyses demonstrated the granite is chemically stable and is ideally suited for use as aggregate.

The whole rock analyses of these 22 samples demonstrated average thorium concentrations of 7.9 ppm (range 6.7-8.9 ppm) and average uranium concentrations of 7.08 ppm (range 6.18-8.15 ppm). These values are typical for Nova Scotia granites. In the rock classification system presented for the South Mountain granite (the rock that underlies much of southwestern Nova Scotia), the Black Point granite would be classified as a muscovite-biotite bearing ‘fine-grained leucomonzogranite’ or FGLMG (MacDonald *et al.* 1992). Average geochemical compositions of 105 FGLMG samples revealed average thorium concentrations of 6.3 ppm with a standard deviation of 4.2 and average uranium concentrations of 7.9 ppm U with a standard deviation of 5.5 ppm. Therefore compositions ranging from 2.1 ppm to 10.5 ppm for thorium and 2.4 ppm to

13.4 ppm for uranium are within one standard deviation of the arithmetic mean for this type of rock and can be considered average compositions.

6.1.6 Acid Rock Drainage (ARD) Potential

The granite at the Project site will be quarried to produce crushed-stone aggregate. Analytical testing was conducted in 2014 on the granite taken from three boreholes drilled in the granite resource (BP-7, BP-8 and BP-9) to confirm its suitability as construction aggregate. Testing included analysis of weight % sulphur and acid production potential as indicators of acid rock drainage (ARD) potential, since ARD has both structural and environmental implications. Testing indicated that the concentration of sulphur / sulphide in the granite is well below the threshold indicated in the *Sulphide Bearing Material Disposal Regulations* and is therefore considered non-acid producing (**Appendix B**). This is fully consistent with the chemical composition of aggregate quality granite: even limited ARD potential would render the rock un-useable as aggregate.

Halifax formation slates, which are often sulphide bearing, and Goldenville formation quartzite and greywacke, which is rarely sulphide bearing, are present within the proposed Project area at the northern end of the site. These rocks underlay the area proposed for the processing plant and aggregate stockpiles (Figure 6.1-6). Although they will not be quarried for aggregate, these formations may be disturbed for construction of the laydown area.

In October 2011, Black Point Quarry project geologists collected samples from these formations for ARD analysis. Five of the six surface samples collected have a sulphide content below the 0.4% threshold stipulated in the Regulations (**Appendix B**). One sample had a sulphide content above the threshold (i.e., 0.935%); however, the material was found to contain some neutralizing capacity with a laboratory-generated pH of 7.4 (i.e., slightly alkaline). From all indications, the Goldenville Formation rock on site is sulphide free and is proposed to be used in construction of the rubble-fill for the wharf. The Halifax Formation, which likely contains sulphides appears to exist only in a small band across the site (**Appendix B**) and will be avoided to the extent possible. As described in Section 7.4, the Proponent will sample and test these rocks prior to any excavation in accordance with the guidance provided in the provincial Sulphide Bearing Material Disposal Regulations. Should sulphide bearing materials be disturbed, the Proponent will work with NSE and NSDNR to confirm that all regulatory requirements are met before excavation begins.

6.1.7 Seismic Activity

Seismic activity may affect operations of any facility, particularly one close to the ocean where a tsunami can have consequences. Figure 6.1-7 shows the distribution and size of historical earthquakes recorded in eastern Canada, while Figure 6.1-8 shows the relative earthquake hazard across Canada. All of Nova Scotia is located within the next-to-lowest low hazard zone.

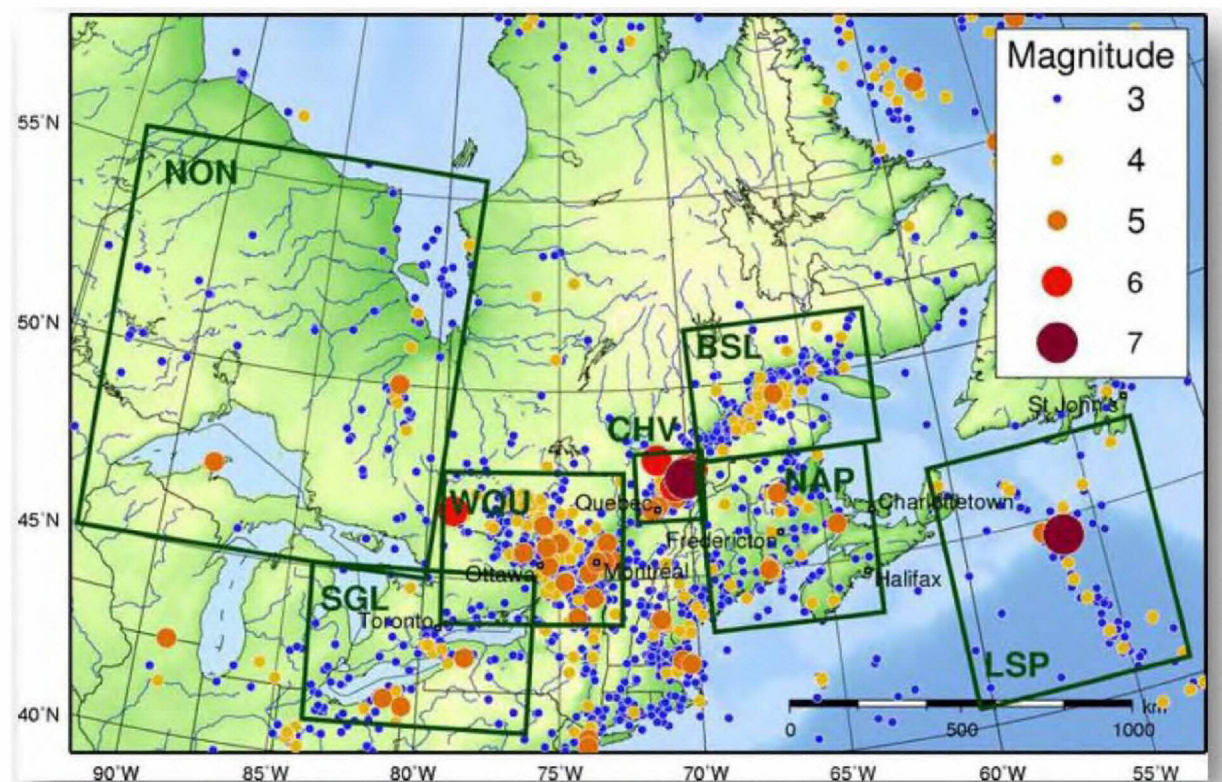

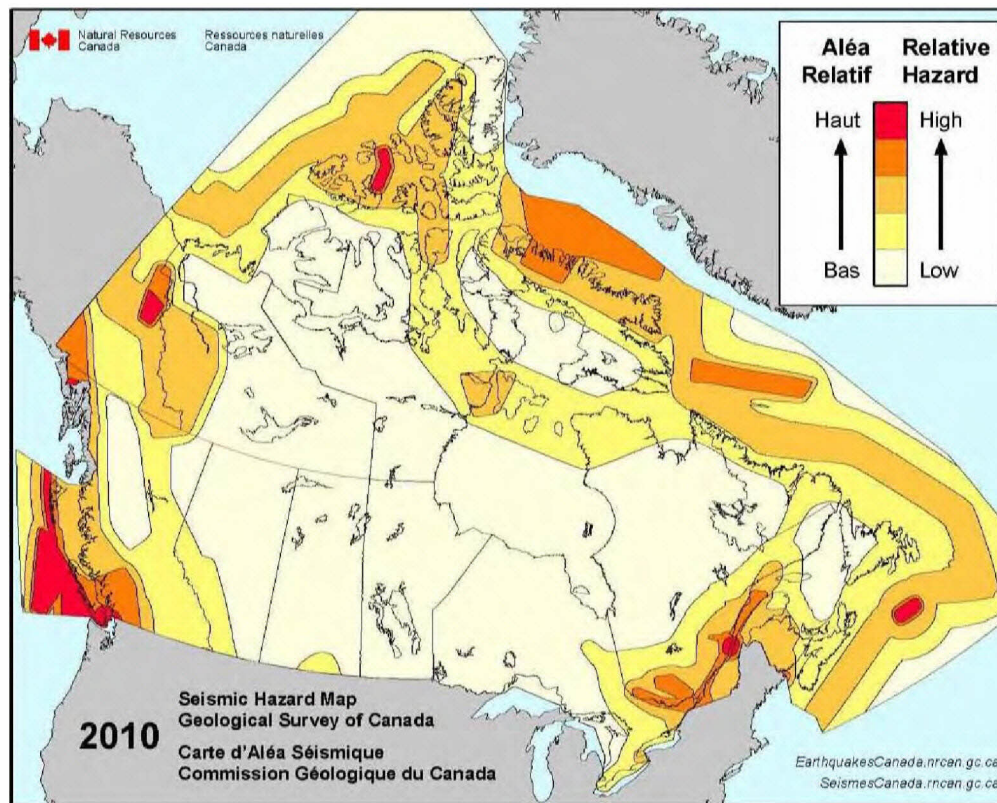

Figure 6.1-7:
Distribution and magnitude of historical earthquakes

Source NRCan 2013a

The rectangles delineate larger scale maps available at Earthquakes Canada. The Laurentian Slope Seismic Zone (LSP) denotes an area off Canada's southeast coast, which includes the Grand Banks of Newfoundland. The Laurentian Slope experienced about nine events 5.0 or greater between 1929 and 1977 (Ruffman 1995). The large red dot within the LSP zone identifies the location of a magnitude 7.2 earthquake that occurred in 1929. Tragically, this earthquake caused a tsunami which killed 28 people on Newfoundland's Burin Peninsula.

**Figure 6.1-8:
 Relative Earthquake Hazard**

Each year, approximately 450 earthquakes occur in eastern Canada, of which four will exceed magnitude 4, thirty will exceed magnitude 3, and about 25 will be reported as felt (NRCan 2013a). A decade will, on average, include three events greater than magnitude 5, generally taken as the threshold of damage.

Earthquakes on Canada's east coast are not caused by tectonic movement along active plate boundaries, as is commonly the case on the west coast. It is thought that seismic activity in this region is related to the large scale, regional stress fields (NRCan 2013a) and slumping of sediment at the edge of the continental shelf into deeper water below.

Although tsunamis are not common, they have been recorded periodically along the eastern seaboard of North America. Ruffman and Tuttle (2005) have summarized tsunamis reported along the eastern continent (quoted from AMEC 2006).

- A local tsunami was noted on June 27, 1864, at St. Shotts on the southwest extremity of the Avalon Peninsula, Newfoundland;
- On November 17, 1872, tide gauges on the Fox Islands in Penobscot Bay and in North Haven, Maine registered a train of tsunami-like waves for about six hours;
- On August 10, 1884, a magnitude 5.6 earthquake in southern New York State created a tsunami that was observed in Philadelphia, along the coast at Trenton and Highlands, New Jersey, and through to New York Harbour;

- On October 4, 1884, three trans-Atlantic cables south of the Tail of the Banks broke at the same time over a down-slope distance of 10 nautical miles suggesting a slump; a possible tsunami may have resulted, however no tsunami reports are presently known;
- On January 9, 1926, an apparent tsunami was seen at Bernard, in Bass Harbour on Mount Desert Island, and at Corea in Maine;
- On November 18, 1929, the magnitude 7.2 "Grand Banks" earthquake (epicentre of 44.5°N, 56.3°W) triggered a large submarine slump that generated a tsunami and caused the loss of 28 lives. It represents Canada's largest documented loss of life directly related to an earthquake; and
- In 1940, a small tsunami-like event observed on the Island of Saint-Pierre may have been associated with the Laurentian Slope Seismic zone.

The 1929 Grand Banks earthquake is the highest magnitude earthquake recorded on the east coast. No damage from this earthquake or the ensuing tsunami was reported in mainland Nova Scotia, although chimneys damaged on Cape Breton Island and minor landslides were reported. The tsunami was reportedly observed as far southwest as Lunenburg as well as in Bermuda. It was recorded on tide gauges as far south as Charleston in the US, in the Azores, and across the Atlantic Ocean in Portugal (NRCan 2013b).

The Black Point Quarry site is located at the edge of the "minor damage" zone for the 1929 tsunami (NRCan 2013b). As indicated in Figure 6.1-7, there are no historical earthquakes reported to originate in or near Cobequid Bay. For reference, reports of the 1929 earthquake were converted to Revised Modified Mercalli Intensities (MMI) and plotted on a map (Figure 6.1-9). Canso records a MMI of 5 out of 10 (shaking: moderate; damage very slight). In summary, the Project site is located in an area of low seismic hazard.

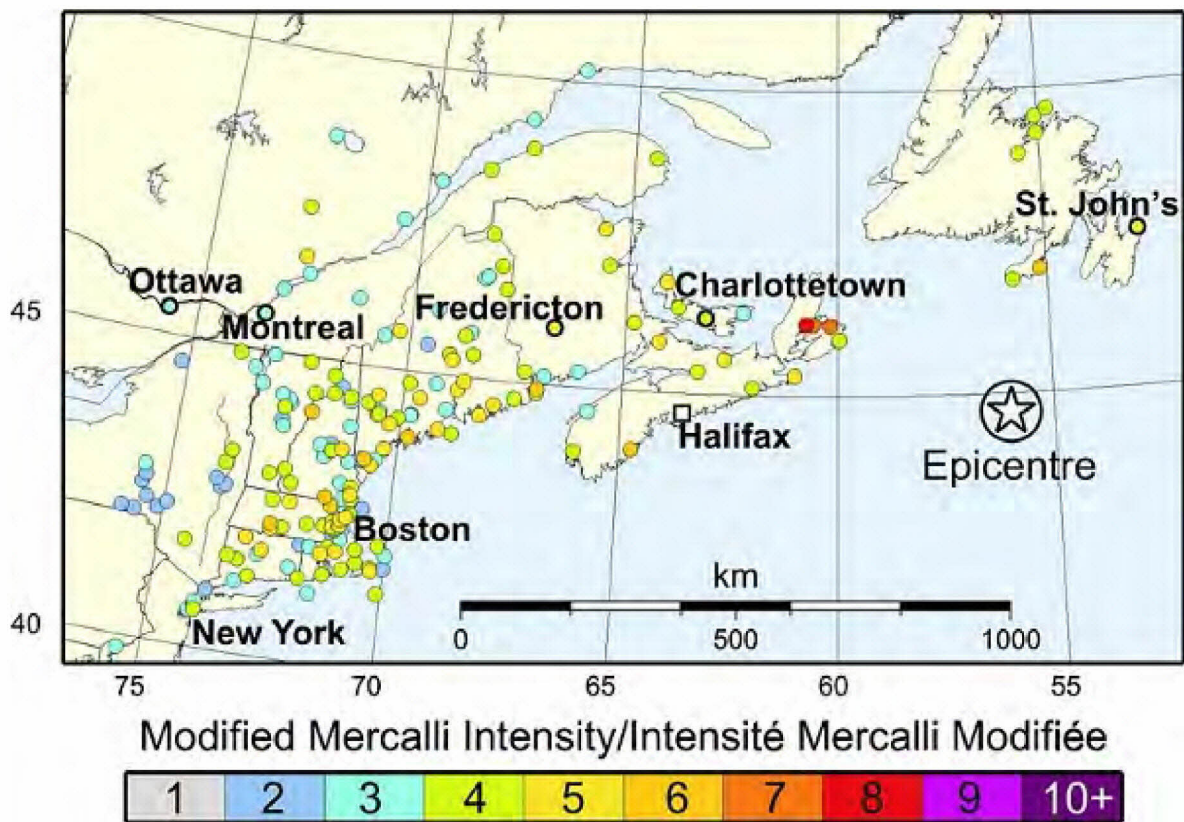

Figure 6.1-9:
Revised Modified Mercalli Intensities for the 1929 Grand Banks Earthquake

Source NRCan 2013c.

6.1.8 Isostatic Uplift and Subsidence

Sea level rise affecting coastal communities and ecosystems results from the combined effect of (a) increased global sea levels and (b) the added effect of regional or “isostatic” subsidence of the Earth’s crust. Uplift and subsidence are the crust’s secondary response to the removal through melting of the glaciers that covered much of Nova Scotia at the end of the last ice age, approximately 10,000 years ago.

At their peak, glaciers located centered in New Brunswick and Newfoundland reached several thousands of metres in thickness. The immense weight of these massive ice concentrations depressed the crustal rocks beneath them. At the same time as the crust beneath the glaciers was depressed, rocks further away from this centre of mass were flexed upward. The following analogy effectively describes this. The subsidence effect is similar to when a person sits upon a seat cushion: the cushion edge is displaced upward even as the centre of the cushion is pushed downward by the weight of the person. Once the weight of the glaciers was removed, the crust beneath the former glacier began to rise to its pre-glacial position, while the crust located further away began to subside as a secondary effect. This subsidence that followed isostatic rebound continues today. In much of Nova Scotia, crustal subsidence is exacerbating the effects of global sea level rise (Fader 2005; King and Fader 1988; Shaw *et al.* 2006).

6.1.9 Landslip Potential

No geotechnical analysis of the site specific conditions for future slope stability has been undertaken for this site. The granite proposed for use as aggregate is known to be highly resistant to fracture and slumping. The landslide potential is very low. The general lack of surficial deposits on the site limits the potential of these materials to fail (i.e., cause a landslide) during a seismic or heavy precipitation event. In addition, any surficial materials overlying the granite rocks will be stripped away prior to quarrying, and therefore will not be susceptible to slumping. Table 6.1-1: presents the geotechnical properties of the rock types found on the property.

**Table 6.1-1:
Geotechnical Properties of Bedrock on the Property**

Geologic Material	Density (pcf)	Compressive Strength psi x 1000	Permeability	Seismic Velocity fps x 1000
Igneous Intrusive	150-200	3-300	Low	12-20
Metamorphic High Grade	150-200	3-25	Low	12-20
	Excavation Difficulty	Resistance to Weathering	Foundation Support	Stability in Cuts
Igneous Intrusive	High	High	Good	Good
Metamorphic High Grade	High	High	Good	Good

Source: Koloski *et al.* 1989

As noted in Section 3.0, the crusher fines will be stored within the quarry itself. These materials are extremely stable when stockpiled. To ensure worker safety within the quarry, the stockpiles are designed to maintain their shape under all weather conditions. As described in Section 7.6, even if a waste rock pile were to slump, it would be entirely contained within the quarry.

6.2 Water Resources

6.2.1 Surface Water

Additional details of the baseline surface water environment are presented in the Surface Water Assessment Technical Report (**Appendix C**). A summary of the key findings is presented below.

6.2.1.1 Watersheds, Water Balance and Peak Flows

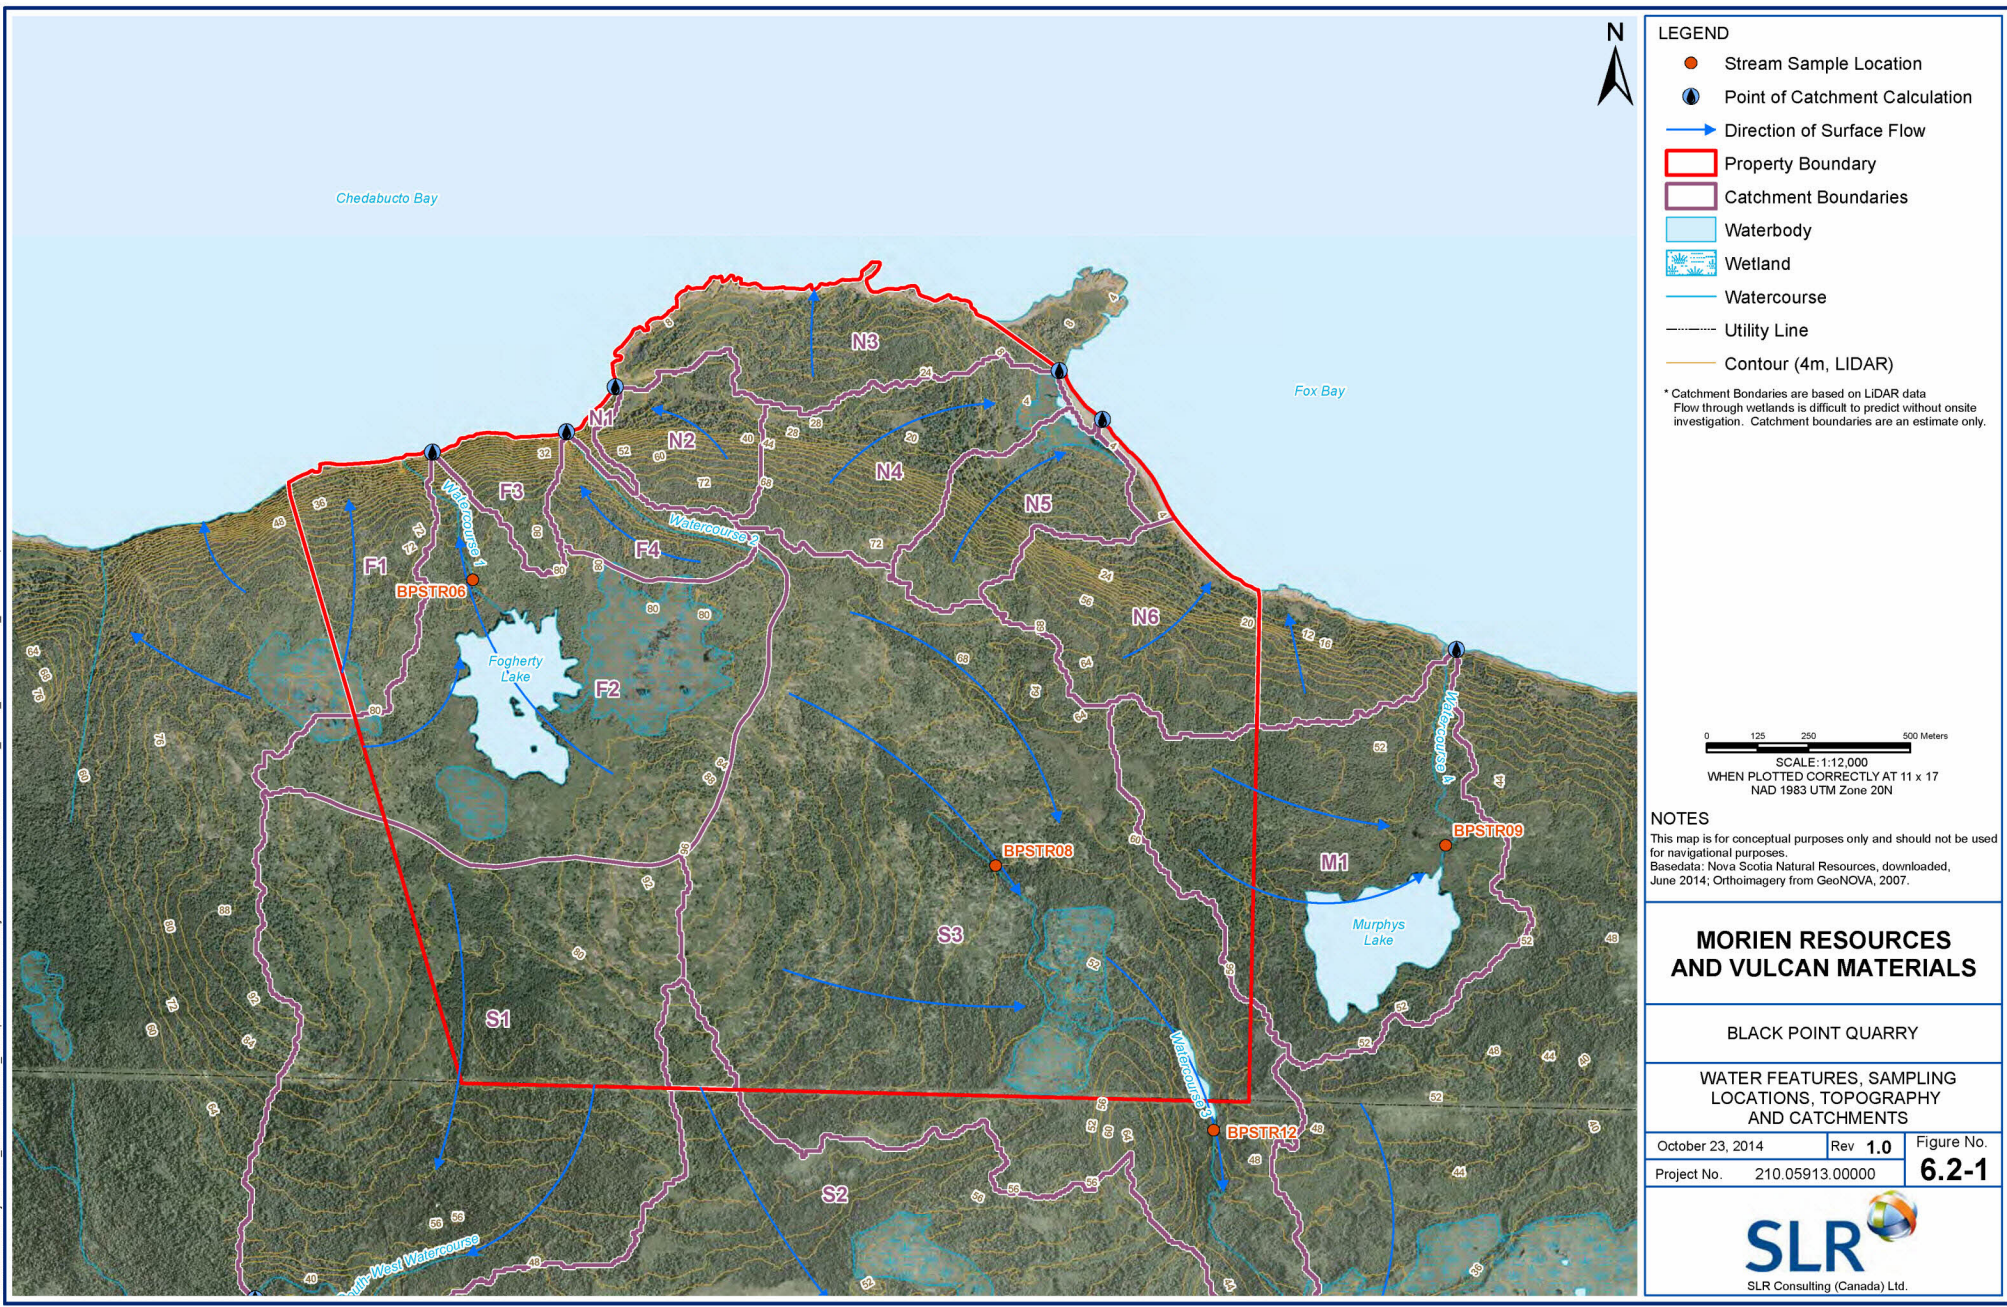

The mean annual runoff for the site has been estimated using a water balance approach, taking account of rainfall and evaporation data (presented in Section 6.3) and an infiltration factor to estimate annual runoff. It is estimated that of the total 1426 mm of annual precipitation, 549 mm evaporates and 351 mm infiltrates into the ground, providing an annual runoff of 526 mm. This equates to 1 865 592 m³ across the entire 354.5 ha site or an average flow of 59 L/s.

The Project site can be divided into 13 catchments, as shown in **Figure 6.2-1**, which drain to off-site watercourse systems (discussed in more detail in the following section) or directly to the ocean. The estimated mean annual for each catchment is presented in Table 6.2-1.

Table 6.2-1:
Catchment Areas and Mean Annual Runoff

Catchment	Flows To	Baseline Scenario (Pre Development)	
		Area (ha)	Mean Annual Runoff (m ³)
F1	Chedabucto Bay	14.4	75 573

Currently, precipitation falling on 54.7% of the site's surface area (193.8 ha) is directed by topography to the north, and discharges to Chedabucto Bay through surface water runoff and groundwater flow. This accounts for all precipitation (minus evapotranspiration) within catchment areas F1-F4, M1 and N1-N6. Some of these catchments, such as F2 and M1, provide surface water and shallow groundwater recharge to Fogherty and Murphys Lake, and the wetlands associated with these lakes. Flow from the remaining 45.4% of the site (160.7 ha) is directed south to wetlands and tributaries of Reynolds Brook.

Peak flows and flood volumes generated by the site during baseline and developed conditions were estimated using the SCS Method as presented in Surface Water Assessment Technical Report (**Appendix C**). As can be observed in the un-mitigated post-development scenario, peak flows will increase by 11% for a 1:25 year event and 8% for a 1:100 year event while the volume of runoff generated post development will be increased by 17% for a 1:25 year event and 13% for a 1:100 year event. Peak flows and flood volumes for the 25- and 100-year storms are given in Table 6.2-2.

**Table 6.2-2:
Peak Flow Rates and Flood Volumes**

Flood Hydrograph	1:25 years	1:100 years
Peak Flow (m ³ /s)	47	62
Flood Volume (m ³)	258 000	341.000

6.2.1.2 *Site Watercourses*

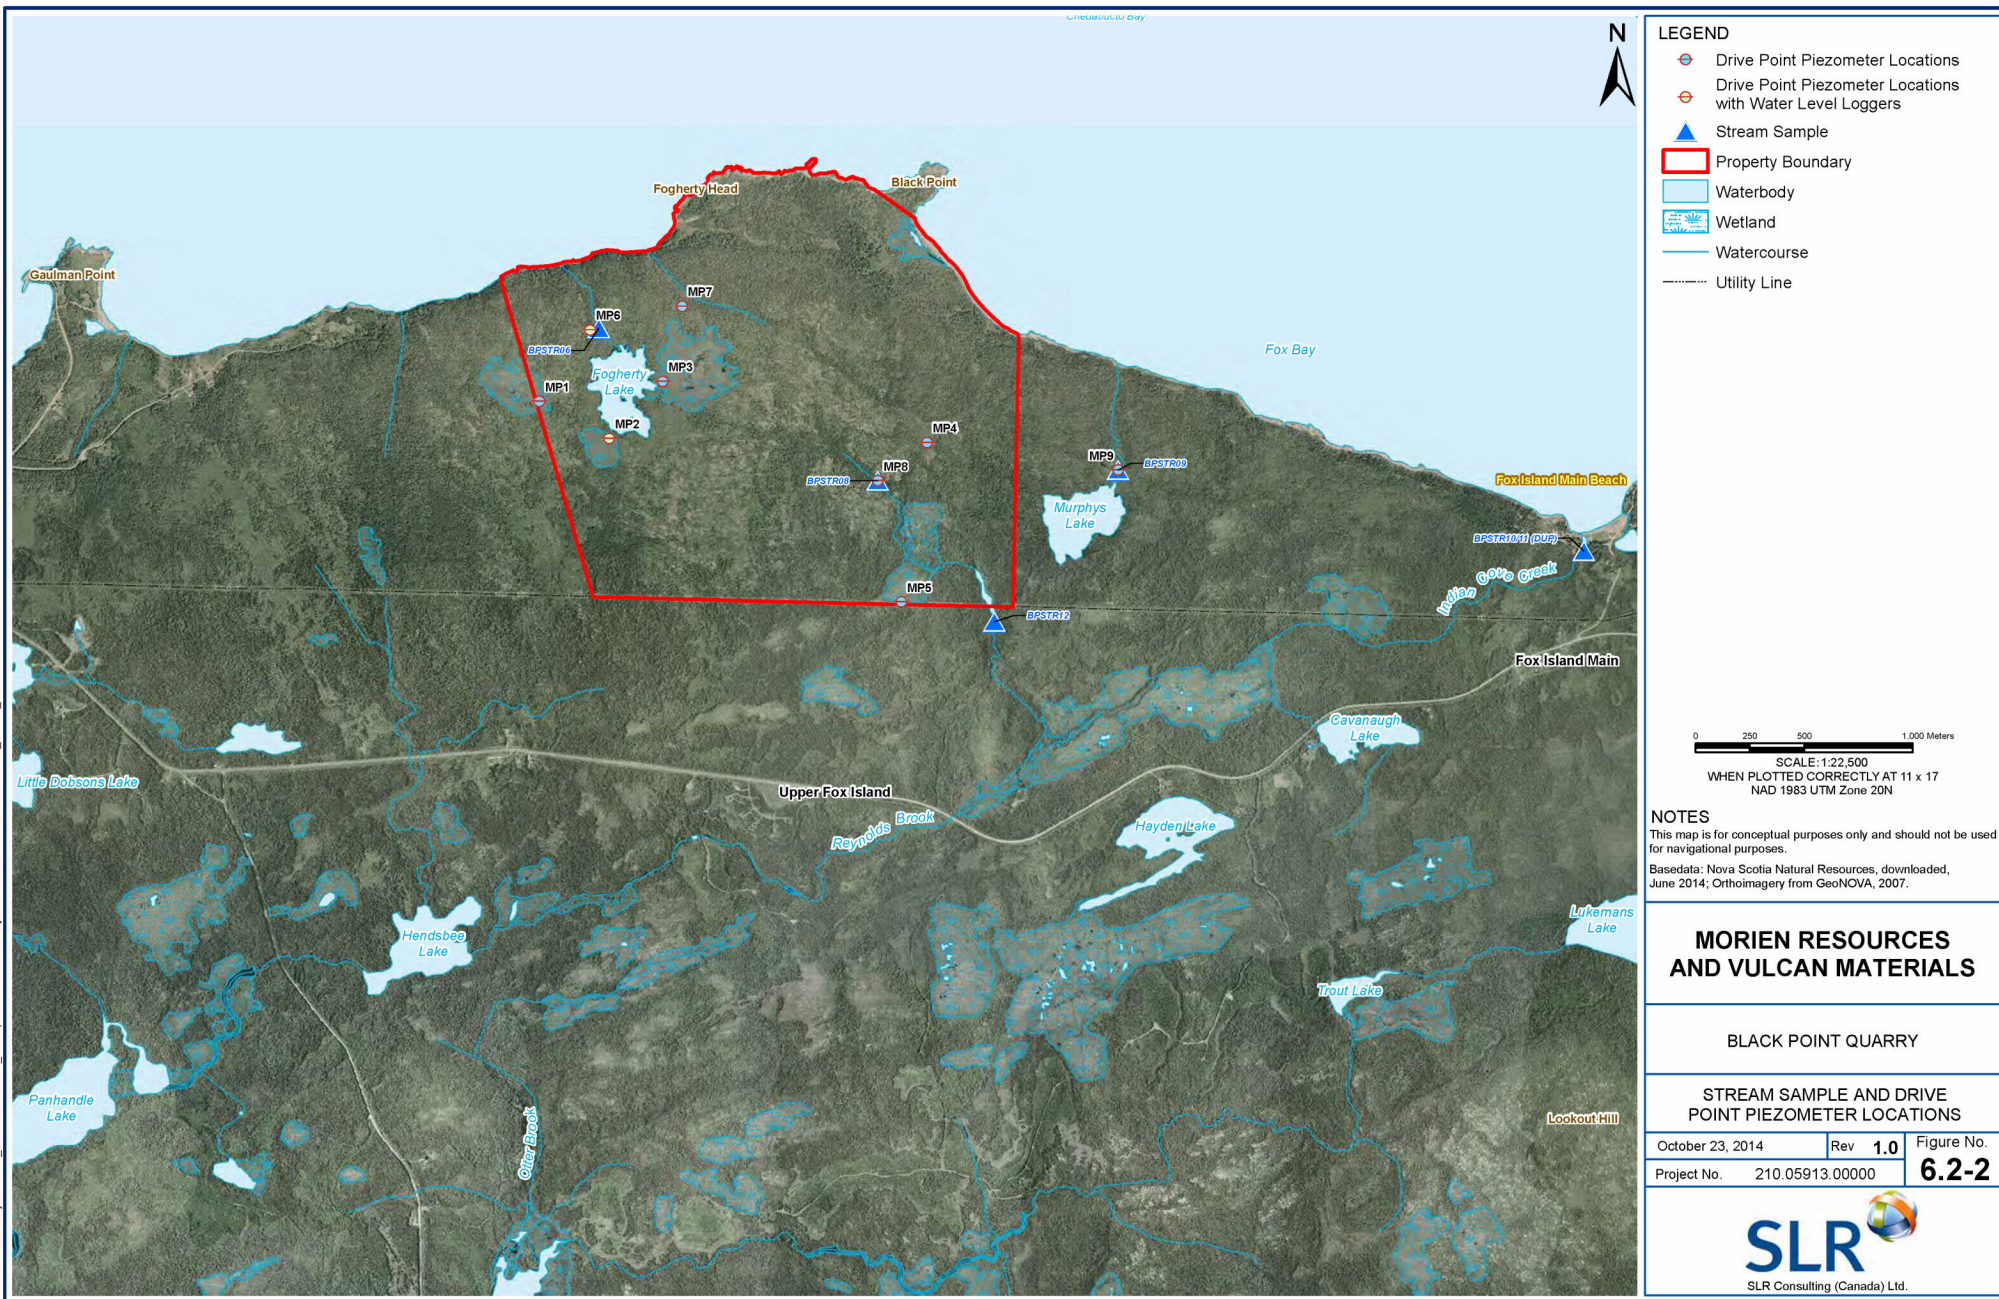

The site hosts numerous wetlands, Fogherty Lake, and three watercourses within the site boundary (**Figure 6.2-2**).

Fogherty Lake is a shallow waterbody surrounded by trees, barrens and exposed rock. The water is clear but darkly tea-coloured, and visibility is nil at approximately one metre depth. The lake substrate is exposed bedrock and large boulders. There is some woody organic debris on the lake bed, which has a strong sulfurous smell. Lake water is very acidic (field pH =2.94) (AMEC 2011 in **Appendix E**).

Three watercourses are identified within the site boundary and are described in full in AMEC's report (Appendix E), a summary of which follows:

- Watercourse 1 – which flows from Fogherty Lake north into Chedabucto Bay. A beaver dam is located near the upstream end of the watercourse. Upstream of the dam, the channel is deep and wide and the substrate largely consists of fines; downstream, the channel is a relatively narrow and shallow run with one area of natural deadwater. The northernmost 150 m of this watercourse was not surveyed, as it flows down a steep slope; however, the dimensions and substrate of the downstream reaches appeared to be similar to the run portions of the channel (AMEC 2011). Flow was measured (2014) and water quality monitored (2011, 2014) approximately 10 m downstream from the discharge of Fogherty Lake at location BPSTR06. The channel varied from approximately 0.50 to 1.0 m wide and had a moderate slope. The stream bed consisted of gravel with varied sized boulders scattered throughout.
- Watercourse 2 – flows within a steep valley from the centre of the site in a north-westerly direction into Chedabucto Bay. There was a great deal of deadfall in the channel valley. The upstream reaches were dry at the time of the 2011 survey, and further downstream the stream was very shallow; this watercourse is probably ephemeral. The stream was dry in July and August, 2014. The last 220 m of this watercourse was inaccessible, as it flows down a steep slope to the ocean, as does Watercourse 1; however, the dimensions and substrate of the downstream reaches appeared to be similar to the rest of the channel (AMEC 2011).

N:\Markham\Project Files\ 2014\210.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\3.WRK\210_05913_StreamAndMPLLocations.mxd

- Watercourse 3 – flows south from the wetlands in the southeast part of the site, across the transmission line cut and towards another wetland system southeast of the site. This in turn is the headwaters of Reynolds Brook, which drains in a south-westerly direction, eventually discharging through Hendsbee and Cooneycoff Lakes into Tor Bay. The downstream portion of the assessed section of Watercourse 3 is a large pool resulting from a beaver dam on the watercourse constructed just south of the site property line. In 2014, flows were measured and water quality monitored at two locations; BPSTR12 which is downstream of wetland 17, and BPSTR08 which is upstream of wetland 17. This watercourse was also sampled in 2011. The discharge measurement at BPSTR12, also on Watercourse 3, was taken at the outflow of Wetland 1. The channel is 2.0 to 10.0 m wide with low, gradual banks, and moderate slope. The stream bed consisted primarily of a mix of small and large boulders. The discharge measurement was located at a narrow, well-contained section 1.0 m wide with large boulders on each side, and consistent flow throughout the section.

The portion of Reynolds Brook nearest to the Property is located approximately 1.0 km southeast of the site. This point (the headwaters of Reynolds Brook) is marked by the discharge from a wetland located southeast of the Property beneath Route 16.

In addition to the abovementioned watercourses, the following significant off-site surface water resources are noted in close proximity to the site:

- South-West (off-site) Watercourse – ephemeral runoff from the south-west of the site drains towards a watercourse which flows to the south-west into Hendsbee Lake, approximately 1.3 km from the site.
- Murphys Lake (Sample ID BPSTR09) - runoff from the east of the site drains towards Murphys Lake which is located approximately 100 m east of the site. Murphys Lake drains to the north into Chedabucto Bay. The discharge measurement at BPSTR09 was measured approximately 20 m downstream from the discharge from Murphys Lake. The typical channel width was 1.0 m or less and had a moderate slope. The stream bed was muddy with fine gravel. The discharge measurement section was 0.80 m wide, had well-defined banks on each side, and had consistent flow throughout the entire section.
- Fox Island Main Creek (Sample ID BPRST10) - Fox Island Main creek drains a large wetland southeast of the Property and discharges north to Indian Cove approximately located 2.0 km east of the Property boundary. None of the surface water draining off the study Property feeds Fox Island Main Creek. Water samples and discharge measurements were taken approximately 10 m upstream from the bridge crossing at Starks Road, Fox Island Main. The typical full-bank channel width is approximately 3.0 m wide, with high banks and a moderate slope. The stream was in low-flow conditions at the time of July and August, 2014 measurements. The stream bed consisted of a mix of gravel and small boulders. The discharge measurement section was 1.1 m wide, well-defined with boulders at each bank, with flow concentrated primarily in middle of the cross-section and negligible at the banks.
- Reynolds Brook – As noted, Reynolds Brook is located south of Route 16 (Marine Drive) at least 1.0 km south of the Property and flows south-west into Hendsbee Lake. Reynolds Brook itself was not inventoried for the presence of fish, but Watercourse 3, which discharges into the wetland that feeds Reynolds Brook, does not support fish.

6.2.1.3 Flow Measurements

Shallow and low permeability soils and the numerous wetlands suggest that relatively low infiltration rates and therefore high runoff rates are typical across the site.

As presented in Table 6.2-3, flow measurements were taken in five watercourses at the end of July 2014 and end of August 2014 (**Appendix C**). The July flows were considered representative of dry (baseflow) conditions (no precipitation for the three days prior to measurements). These measurements show flow out of Fogherty Lake in Watercourse 1 to be 0.03 L/s and flow out of the southeast wetland in Watercourse 3 to be 7.7 L/s. The August flows were also considered representative of low flow conditions and measured flows were consistently lower than during the July round of measurements.

**Table 6.2-3:
Stream Discharge Summary**

Sample ID	Location Description	Discharge (L/s)	Dates Measured (2014)
BPSTR06	Fogherty Lake Outflow Watercourse 1	0.031 / 0	July 30 / Aug 27
None	Watercourse 2	0 / 0	July 30 / Aug 26
BPSTR08	Wetland 17 Inflow Watercourse 3 Upstream	0 / 0	July 30 / Aug 26
BPSTR09	Murphys Lake Outflow	0.170 / 0	July 31 / Aug 27
BPSTR12	Wetland 1 Outflow (Watercourse 3 downstream)	7.73 / 0.325	July 31 / Aug 27
BPSTR10	Fox Island Creek Outflow	4.24 / 0.394	July 25 / Aug 27

6.2.1.4 Water Quality

Surface water quality monitoring was undertaken at 5 locations on 31st July, 2014. These samples were intended to complement data collected in August and September, 2010 at many of the same sample locations, including Fogherty Lake (AMEC 2011 – **Appendix E**). The analytical results were compared against Canadian Water Quality Guidelines (CWQG) for the Protection for Aquatic Life (PAL) Freshwater Guideline Update 7.0 (CCME 2007). The results indicate:

- Laboratory-measured pH was low (4.33 – 4.70) in all 5 samples and is outside of the acceptable CWQG PAL guideline range (6.5-9.0).
- Lead slightly exceeded the CWQG PAL guidelines at two locations.
- Iron was elevated (320 – 1600 ug/L) in all 5 samples and exceeded the CWQG PAL guidelines (300 ug/L).
- Cadmium was above the CWQG PAL guidelines at one location (0.09 ug/L).
- Ammonia was elevated (0.08 – 0.086 mg/L) in 2 samples and exceeded the CWQG PAL guidelines (0.05 mg/L).
- Aluminium was elevated (270 – 820 ug/L) in all 5 samples and exceeded the CWQG PAL guidelines (5 ug/L).

The pH of surface water features is low and colour of water is typically dark brown, both characteristics are thought to be attributable to the peaty soils which are common across the site. The low pH is likely to be the cause of the elevated dissolved metals concentrations within

the samples. None of the on-site watercourses support fish habitat. Water quality data from 2010 and 2014 are presented in **Appendix C**.

6.2.1.5 *Surface Water Use*

No consumers of surface water were identified within two kilometers of the property boundary. As noted, the freshwater streams on the property, including Fogherty Lake, do not support fish populations and so are not used for recreational fishing. No industrial water taking occurs within two kilometers of the Project site. A Designated Water Supply Area (the Walsh or Wilkins Lake Water Supply Area) is located 4.5 km southeast of the property boundary. This water supply area is located within a separate watershed that does not receive surface water runoff from the Project site.

6.2.2 *Water Supply Potential*

Given the yields of wells in the vicinity of the Project (Section 6.2), groundwater is unlikely to yield sufficient water to meet development needs. Surface water bodies in the area are not suitable for processing water due to their acidity. In light of this, the Project will capture rainwater and snowmelt to meet water requirements.

The estimated mean annual runoff from the quarry and lower platform areas which will drain into the stormwater ponds and will be available for use in the processing plant and for dust suppression is estimated to be 1 248 202 m³, which equates to an average flow of 3 420 m³ per day during the fully developed site. However, runoff volumes will be lower during the initial stages of site development. Prior to excavation of the quarry, the mean annual runoff from the lower platform is expected to be 161 467 m³ (442 m³ per day). This volume will be sufficient, when stored to meet Project requirements, estimated at 315-378 m³ per day for the expected 10-12 hrs of operation during Phase 1 and rising to about 3 859 m³ per day during Phase 3.

6.2.3 *Ground Water*

The Project site is not equipped with municipal water or wastewater services. The nearest municipal water supply is located in Canso, approximately 10 km east of Black Point Quarry property. Residents in the communities of Fox Island Main, Upper Fox Island along Highway 16, and Half Island Cove, rely on groundwater wells for their potable water, and each house has a private septic system.

A residential well survey was conducted in July and August, 2014 to document the number of dug and drilled wells in the vicinity of the Project site, residential water quality, and water supply aquifer characteristics. This was combined with permeability testing undertaken on boreholes drilled in the granite proposed for aggregate use, and (as noted above) stream water sampling, stream flow measurements, installation of piezometers to evaluate discharge/recharge conditions in site wetlands, additional water samples taken from the granite boreholes and a number of water level measurements in these boreholes. The following sections provide information regarding groundwater conditions at and around the site, and describe the likely effects of the quarry on local groundwater supplies. Additional information regarding groundwater is found in the Hydrogeological Technical Report presented in **Appendix A**.

Regional Groundwater Characteristics

The Nova Scotia Well Logs Database is a compilation of water supply well information provided to the province by licensed well drillers over the past several decades (NSE 2014a). The database typically contains information regarding well construction and lithology (rock types) but may also provide information on aquifer characteristics.

A total of 16 drilled wells are reportedly present within 2.0 km of the property boundaries. Most of these wells are located in Fox Island Main and along Highway 16 and were visited during the residential well survey. This information, combined with the residential well survey, provides a comprehensive data set regarding local water supply. Available data extracted from NSDNR's Interactive Groundwater Map (<http://gis4.natr.gov.ns.ca/website/nsgroundwater>) from the 16 drilled wells are presented on Table 6.2-4. No well logs data are available regarding dug wells.

**Table 6.2-4:
Well Characteristics within Two Kilometres of the Property**

Well Number	Address / Community	Depth (m)	Casing (m)	Depth to Bedrock (m)	Static Level (m)	Yield (Lpm)	Elevation (mASL)	Easting	Northing

Average		68	12	7.6	5.2	10.4			

Table 6.2-4 indicates that surficial cover over bedrock is generally less than 10 m deep and drilled wells in the area typically range from 40 to 80 m deep (average 68 m). The water table is usually found about 5-6 m below ground surface.

Regionally, drilled well hydraulic characteristics are also reported in the database, for both metamorphic (Goldenville and Halifax Formation) and plutonic (granite) rocks (Table 6.2-5).

**Table 6.2-5:
Drilled Groundwater Well Regional Hydraulic Characteristics**

Region Name	Median Apparent Transmissivity (m2/day)	Median Q20 (Lpm)	Median Specific Capacity (m3/d/m)	Minimum Apparent Transmissivity (m2/day)	Maximum Apparent Transmissivity (m2/day)	Minimum Q20 (Lpm)	Maximum Q20 (Lpm)	Minimum Specific Capacity (m3/d/m)	Maximum Specific Capacity (m3/d/m)
Metamorphic	1.26	19.75	2.09	0.01	206.2	0.5	1801.11	0.01	448.29
Plutonic	1.43	22.7	2.47	0.06	320	1	1009	0.1	164.09

Similar hydraulic data are available on a regional basis for the surficial aquifer (Table 6.2-6).

**Table 6.2-6:
Surficial Deposit Regional Hydraulic Characteristics**

Groundwater Region Name	Median Apparent Transmissivity (m2/day)	Median Q20 (Lpm)	Median Specific Capacity (m3/d/m)	Minimum Apparent Transmissivity (m2/day)	Maximum Apparent Transmissivity (m2/day)	Minimum Q20 (Lpm)	Maximum Q20 (Lpm)	Minimum Specific Capacity (m3/d/m)	Maximum Specific Capacity (m3/d/m)
Glaciolacustrine/Till Plains/Colluvial	79.9	113.85	82.1	8.7	262.49	28.2	172.7	11.96	255.59

Both bedrock and surficial aquifers provide sufficient water quantities for residential use. Data from pumping tests completed in 1973 on two nearby wells are also reported from NSDNR's Interactive Groundwater Map Table 6.2-7. One well is located east of the site, at Sea Breeze Campground, and one is located west of the site, at the former Half Island Cove School near Dobson's Lake.

**Table 6.2-7:
Pumping Test Data, 1973**

Community	Test For	Formation	Depth (m)	Static (m)	Average Rate (m3/d)	Available Draw Down (m)	Max Draw Down (m)	Tapp (m2/d)	SC (m2/d)	Q20 (m3/d)	Q20 (l/min)	Easting	Northing
Fox Island Main	Sea Breeze	Goldenville	48.8	7.6	98.18	32	31.8	2.5	3.01	42.5	29.5	649076	5023051
Half Island Cove	School	Halifax	45.7	3	32.73	33.4	5.5	4.1	5.8	75.3	52.3	641188	5022332

Note: Tapp = apparent transmissivity; SC = specific capacity; Q20 = safe yield (20 year long-term yield)

The data indicate these two bedrock wells have intercepted significant water bearing fractures and are able to provide considerable volumes of water over the long term.

Regional groundwater chemistry for both bedrock and surficial deposits is presented in NSDNR's Interactive Groundwater Map. Table 6.2-8 presents bedrock water chemistry, which is generally based on over 200 water samples in the region. The rock type is reported as "metamorphic" indicating that these data were compiled from wells installed in Goldenville and Halifax Formation rocks, rather than the granite.

**Table 6.2-8:
Regional Bedrock and Surficial Aquifer Chemistry**

	Groundwater (Bedrock)	Groundwater (Surficial)
HCO ₃ (mg/L)	63	39
Alk (mg/L)	65	37
Na (mg/L)	17	11
K (mg/L)	1.2	1.5
Ca (mg/L)	22.5	20.3
Mg (mg/L)	3.3	3.7
F (mg/L)	0.17	0.05
SO ₄ (mg/L)	11	11
Cl (mg/L)	16	18
Hrd (mg/L)	70.5	68.8
TDS (mg/L)	149	153.5
pH	7.7	6.9
NO ₃ - NO ₂ N (mg/L)	0	0.4
As (ug/L)	1.45	1
U (ug/L)	0.3	0.2
Fe (ug/L)	125	50
Mn (ug/L)	65	13

Regional groundwater quality is similar for many parameters, with the notable exceptions of pH, which tends to be lower in surficial groundwater and metals, which are also lower in surficial aquifers. Bedrock groundwater tends to be “harder”, containing more dissolved minerals and bicarbonate.

In addition, the Interactive Groundwater Map indicates that radionuclide potential is regionally “very likely” in granites and rocks immediately adjacent to granite in this area (i.e., within 1 km), and “likely” outside of this limit. Similarly, arsenic risk is regionally “very likely” throughout the area, from Canso to Queensport and beyond.

Residential Groundwater Characteristics

The objective of the residential well survey was to introduce the Project to residents living nearest to the site, respond to their questions, gather information regarding their well construction and water quality (to the extent this was known), collect water samples and undertake brief drawdown tests where permitted. The residential well survey included all residences at an approximate distance of 2 km west and south of the property, and all residences within about 3.5 km west of the site. This is referred to as “the vicinity of the Project” and includes all residences on Half Island Cove Road to the junction of Half Island Cove Wharf

Road; residences along Highway 16 between Route 316 and Fox Island Main Road; and residences along Fox Island Main Road and Starks Road in the community of Fox Island Main.

Of all the civic addresses visited in the vicinity of the Project, the majority (17 of 23 or 74%) obtain potable water from shallow dug wells excavated in surficial deposits. No surface water streams or lakes are used for potable water. A drilled well is present immediately south of the property boundary on Highway 16, while the remaining five drilled wells are located in Fox Island; three of these five wells are located east of Indian Cove, more than 3 km from the Property boundary. Sampled and non-sampled wells are summarized on Table 6.2-9.

Note: addresses are not given to protect privacy.

A total of 14 water samples (not including duplicates) were taken during the residential well survey. All targeted wells (defined as those closest to property boundary) were sampled, as well as additional well in the immediate vicinity. Samples were collected from 11 dug wells and 3 drilled wells, as shown on Table 6.2-9 above and on **Figure 6.2-3**.

Groundwater quality measured at residential wells is presented in Table 6.2-10.

NOTES:

NV = no value

Canadian Drinking Water Quality CDWQ Guidelines: Aug 2012

3. Aluminum Aesthetic Objective (CDWQ - AO): Conventional Treatment Plants = 0.1 mg/L (100 ug/L), Other Treatment Systems = 0.2 mg/L (200 ug/L)

4. pH Objective (CDWQ): 6.5 - 8.5

5. Calculated result only includes measured parameters. Actual TDS may be higher.

6. Sample results likely affected by water softner treatment system

BOLD RED Exceeds guideline

Canadian Drinking Water Quality CDWQ Guidelines: Aug 2012

3. Aluminum Aesthetic Objective (CDWQ - AO): Conventional Treatment Plants = 0.1 mg/L (100 ug/L), Other Treatment Systems = 0.2 mg/L (200 ug/L)

4. pH Objective (CDWQ): 6.5 - 8.5

5. Calculated result only includes measured parameters. Actual TDS may be higher.

6. Sample results likely affected by water softener treatment system

BOLD RED Exceeds guideline

Groundwater in the surficial deposits sampled in dug wells is generally high quality, with the only exceedances of the Canadian Drinking Water Quality (CDWQ) guidelines occurring in the aesthetic objective parameters iron, manganese and pH, and a small number of exceedances of the turbidity CDWQ guideline. The groundwater quality in the surficial deposits is indicative of recharge from rainfall having a short residence time in the subsurface, where fewer parameters have time to dissolve in the groundwater.

Groundwater in drilled wells is also generally of good quality with only one or two samples exceeding the aesthetic objectives for manganese and turbidity. Two samples plus a field duplicate from a single residential well² demonstrated arsenic concentrations which exceed the CDWQ Guideline. As noted above, the NSDNR Interactive Groundwater Map indicates that elevated arsenic concentrations are common in this region; in fact elevated arsenic in groundwater is well documented in the Goldenville Formation (Dummer *et al.* 2014).

Aggregate Granite Groundwater Characteristics

A total of 11 boreholes have been drilled within the granite to sample and assess the rock suitability as an aggregate source. Detailed drill logs describe the lithological and structural attributes encountered in the boreholes. Borehole depths ranged from 56 m to 136 m. Static water levels recorded in 2011 and 2014 are presented in Table 6.2-11.

N:\Markham\Project Files\ 2014\210.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\4 BPT\BPT HydroGeologicAssessment\210_05913_RPT_HYD_ReadWellAndBoreholes.mxd

As described in the Hydrogeological Technical Report (**Appendix A**), the granite bedrock is a crystalline rock with negligible primary porosity. Groundwater movement occurs within the joints and fractures. Analysis of fracture frequency reported in the drill logs indicates that the highest frequency of fractures within the granite occurs in the upper 40 m. Two fault zones were noted in the core logs for BP-8 and BP-9 and depending on their nature may act as preferential pathways or boundaries to groundwater flow. It appears that most groundwater flow occurs in the upper 40 m.

A number of slug and pumping and recovery tests were undertaken on granite core holes BP-5, BP-7, BP-8 and BP-9 (**Appendix A**). Initial slug tests indicated hydraulic conductivities of approximately 6×10^{-7} m/s to 7×10^{-7} m/s, however, later pumping and recovery tests indicated hydraulic conductivities of 2×10^{-7} m/s to 6×10^{-7} m/s. It is considered that the longer pumping and recovery tests give a better idea of the bulk granite properties due to their larger water level changes and radius of influence around the wells.

Groundwater samples were taken from four of the granite boreholes on two occasions. On the first occasion (June), a bailer was used to remove ten bailer volumes (approximately 10 L) of water prior to sampling. On the second occasion (August), an electric pump was used to withdrawn water from the well for approximately one hour before sampling. Field measurements (temperature, electrical conductivity and pH) were measured at 15 minute intervals to determine when to sample; when these parameters stabilized, water samples were taken³. Water quality results from both sampling events are presented in Table 6.2-12.

³ Pumping parameters prior to sampling were: BH-5: 6.3 L/min for 135 min; BH-7: 5.7 L/min for 30 min; BH-8: 3.2 L/min for 135 min; BH-9: 2.6 L/min for 99 minutes.

Notes:

NV = no value; "--" = not measured

5. Calculated result only includes measured parameters. Actual TDS may be higher.

In general, groundwater in the granite exhibits elevated concentrations of metals such as aluminium, iron, manganese, lead, arsenic and uranium when compared to surface water samples. The parameter pH was low in two of eight samples (ranging from 5.05 to 5.85), indicating neutral to slightly acidic conditions within the granite. The reported arsenic and uranium concentrations are considered background levels: regional maps prepared by the province indicate that elevated concentrations of arsenic are considered very likely in the area (NSE 2005) and uranium is considered most likely to occur in areas containing granitic intrusions (NSE 2014b). Background uranium concentrations in the granite bedrock are described in Section 6.1.5.

Discharge and Recharge

Nested-pair or single drive point mini-piezometer (MP) pairs are currently in use at nine locations to determine groundwater recharge and discharge on the Property. Five piezometer installations, including piezometers MP1, MP2 and MP5 installed in wetlands, along with streams at locations MP6 and MP8 indicate downward gradients which suggest aquifer recharge is occurring at these locations. Upward vertical gradients measured at wetland areas MP3, MP4 and MP7, along with the stream at MP9 indicate that discharge from the aquifer is occurring at these locations.

6.3 Atmospheric Resources

6.3.1 General Climate and Weather Patterns

The climate of Nova Scotia is generally moderate and moist due to the surrounding bodies of water (Gulf of St. Lawrence to the north, Bay of Fundy to the west, and Atlantic Ocean to the south and east). During the summer, Nova Scotia experiences warm temperatures with winds originating from the south. This is attributed to high pressure systems moving up the Atlantic Coast from the tropics. In the winter westerly and northwesterly winds bring cold air from the northern interior of Canada to Nova Scotia.

Historical climate records were obtained from weather stations near the proposed Project site. The following Meteorological Service of Canada (MSC) weather stations were considered to represent the Project site.

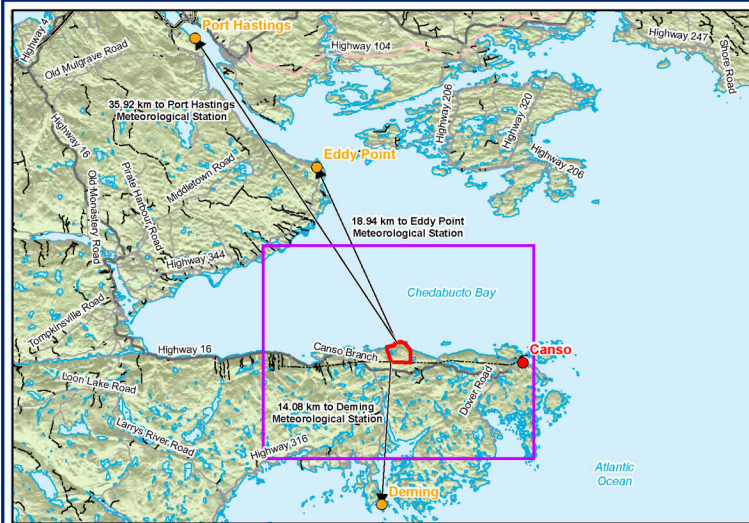

- Deming, N.S. [45°12'59.007"N, 61°10'40.090"W];
- Port Hastings, N.S. [45°38'00.000"N, 61°24'00.000"W];
- Eddy Point, N.S. [45°31'00.000" N, 61°15'00.000" W].

A map of the surrounding area showing the location of each meteorological station is provided as **Figure 6.3-1**. The approximate distance to these stations from the Project site is 19.8 km northwest for Eddy Point, 15 km southwest for Deming Point, and 37 km northwest for Port Hastings. Although the data accumulated from Eddy Point are older, it is more representative of the Project site due to its location on the coast of the Chedabucto Bay. None of these weather stations currently collect climatic data. Table 6.3-1 summarizes climate data collected from these stations.

**Table 6.3-1:
Climate Near the Project Site**

Project No.	210.05913.00000	6.3-1

6.3.1.1 Temperature and Precipitation Normals and Extremes

It is assumed that the climate normals for Deming, which is 15 km southwest of the Project site, are generally representative of the climate at the Project site. The design of mitigation measures and assessment of impacts are not heavily influenced by slight changes in climate normal, as would be expected from slightly longer data records. Temperature and precipitation normals recorded at the Deming, N.S. weather station are shown in Table 6.3-2. The extreme temperatures (i.e., weather events occurring <5% of the time) recorded by this weather station ranged from -25°C and +31.1°C.

At Eddy Point approximately 20 km northwest of the site, freezing rain and snowfall amounts are highest between the months of October and May, with December through to March are typified by the heaviest precipitation events (EC 2014a). According to monthly totals recorded for the years 1951-1980, Eddy Point typically experiences monthly rainfall amounts ranging from a low of approximately 89 mm to a high of approximately 165 mm, while Deming records from 75 mm to 145.2 mm (1981-2010).

More recent temperature data from the Hart Island station (45°21'00.000" N, 60°59'00.000" W) near Canso, N. S. are presented in Table 6.3-3. This station is located approximately 13.9 km east of the Project site. However, the precipitation data were not available for the Hart Island station.

6.3.2 Wind Normals and Extremes

Sea breezes, a wind that blows inland from the ocean at typically low wind speeds, are common along coastal regions of the province. This is due to the difference in solar insulation of land and ocean surfaces. As the land and ocean absorbs heat from the sun, warmed air rises from these surfaces which lower the pressure. The air above the surface of the ocean warms more slowly than the land, so air pressure over the ocean is higher than air pressure over the land. Wind will naturally blow from areas of higher surface pressure to lower surface pressure resulting in daytime sea breezes. The reverse can occur at night, but due to the cold coastal waters, these "land breezes" do not typically occur in Nova Scotia. Sea breezes are light in nature and accordingly will only have minimal impact on the quarry and marine facility. In addition, sea breezes, which are most common from May to October, generally come from the southwest and therefore the marine terminal will be in the lee of the land, further reducing the impact from breezes.

During the winter season, the wind typically comes from the west and northwest at an average speed of 22 km/h. In the summer, the wind typically blows from the south and southwest with an average speed of 10-15 km/h (EC 2006a). Chedabucto Bay often experiences easterly gales since the wide entrance to the Bay faces the open ocean in an easterly direction. The average and extreme wind speed and directional values are displayed in Table 6.3-4.

**Table 6.3-4:

40.0 (74.1)	0.01

Source: Atmospheric Environment Branch. Canadian Climate Normals 1951-1980. (MSC 2002)

The MSC50 Environment Canada hourly wind data were also used to characterize the wind conditions for the Project site (CBLC 2010). The annual wind rose and location from the MSC50 data is presented in **Figure 6.3-1**. Note, the MSC50 data is from a wind hindcast model, which generated 54 years of hourly wind direction and intensity from many sources and are not real-time measurements such as those presented above. The MSC50 data is from a single grid point located approximately 6 kilometres northeast of the Project site. This grid point was selected because it was the closest of the six available MSC50 grid points in Chedabucto Bay. It is anticipated that the wind and wave conditions at this grid point will differ somewhat from the conditions along the coastline at the Project site, as it is located towards the middle of Chedabucto Bay. The model showed winds predominantly from the northwest during the winter and fall months and predominantly from the southwest during late spring and summer months.

Data for wind direction and intensity, and wave direction and height, both in percentage and hours per year, are given in Table 6.3-6. These data indicate that winds in excess of 20 m/s (i.e. 72 km/h) were present 0.42% of the year (36.51 hours) when averaged over the past 54 years. Winds in excess of 27 m/s (97 km/h) were not recorded on a yearly basis, when averaged over the past 54 years. Wave heights at the MSC50 grid point near the Project site were less than 2 metres in height 92.77% of the time whereas waves from 2 to 3 metres and 3 to 4 metres were present 5.96% and 1.02% of the time, respectively. Waves in excess of 4 metres were relatively minor and only present over 0.25% of the year on average.

6.3.3 Adverse Weather

The Atlantic coast of Nova Scotia and the south coast of Newfoundland experience more storms over the course of one year than any other region in Canada (EC 2006a). These storms bring high winds along the coast, heavy precipitation, storm surges exceeding 1.0 m, freezing rain, and peak waves nearing 14 meters in height (EC 2006a). The winds that affect the coast and mainland Nova Scotia can exceed 150 km/h, and may result in extreme wind chills during the winter. Additionally, Nova Scotia can experience reduced visibility due to precipitation events and fog, as well as blizzards and ice storms in the winter.

Nova Scotia lies within the limit of the Atlantic Hurricane system. Hurricanes tend to develop within or east of the Caribbean Sea with many storms moving up the eastern seaboard. There have been 19 Atlantic hurricanes that have made landfall in Nova Scotia over the past 100 years (Environment Canada 2014d). Of these, 16 were Category 1 storms with wind speeds from 119 to 153 km/h and three were Category 2 intensity with wind speeds from 154 to 177 km/h. In the past 100 years there have been no storms reaching Category 3, 4 or 5 intensities. In addition, over the past 100 years there have been 19 tropical storms (wind speeds from 63 – 118 km/h) that have made landfall in Nova Scotia. The potential impacts on Nova Scotia, especially in coastal regions including the Project site in Chedabucto Bay where these storms may make landfall, are high winds, storm surges and heavy rainfall. Additional information regarding the impacts of severe weather, including climate change effects, is presented in Section 8 Effects of the Environment on the Project.

The majority of Atlantic hurricanes and tropical storms that move up the eastern seaboard dissipate or are significantly attenuated as they come into contact with the cold waters off the northeastern coast of Canada and the United States. The resulting impact on coastal regions of Nova Scotia is heavy tidal swells and high waves. The peak hurricane season in Nova Scotia usually falls between September and October. It should be noted however that hurricanes have been landing in Nova Scotia more frequently as of late, including Hurricane Juan in 2003, and can develop outside the September – October period (Wightman 2012).

Given its position extending into the Atlantic Ocean, Nova Scotia, especially coastal regions, experiences a considerable number of fog days, typically in the spring to early summer. Halifax International Airport has 122 days/yr with at least 1 hour of fog, largely due to the chilled air above the Labrador Current mixing with the moist warm air from the Gulf Stream. Coupled with sea breezes, these bands of fog that lie off the coast of Nova Scotia during the daytime hours have a tendency to move inland into the bays and inlets at night. The nearest station to the Project site monitoring this data is near Canso. Canso is approximately 12 km from the Project site and is an appropriate representation of conditions at the Project site because both locations are along the southern coast of the Chedabucto Bay. Canso experiences 115 days/yr of at least 1 hour of fog cover (EC 2006a).

Fog, ice fog, freezing fog, precipitation and other severe weather can pose a serious threat or risk to marine vessels in the proposed Black Point area. The monthly average number of occurrences with adverse weather that were monitored at South Side Harbour Station near Canso, N.S. is presented in Table 6.3-7 (Farmzone 2014).

**Table 6.3-7:
Adverse Weather Events at South Side Harbour, N.S. Over Last 30 Years**

Days With	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sept	Oct	Nov	Dec
Freezing Rain / Freezing Drizzle	5	3	2	2	0	0	0	0	0	0	1	1
Thunderstorms	0	0	0	0	0	0	1	0	0	0	0	0
Hail	0	0	0	0	0	0	0	0	0	0	0	0
Fog, Ice Fog, Freezing Fog	Data Unavailable											
Haze or Smoke	Data Unavailable											
Blowing Dust	Data Unavailable											
Blowing Snow	Data Unavailable											

Source: Farmzone 2014. The Weather Network 2014. Adverse Weather for Canso, N.S.

Note: Fog Forms, Haze/Smoke, and Blowing Dust/Snow were not recorded over the 30 years that data were collected from the South Side Harbour Station in Canso, N.S. However, 115 days of fog persisting for at least 1 hour were recorded in Canso, N.S. in 2013 (EC 2006a).

On the coastline of Chedabucto Bay, visibility can often be reduced to one-half nautical mile twelve months of the year. However, reduced visibility attributed to dense fog is much more likely in the late spring and early summer (July being the month with the most fog) when the warm air from the south flows over the cold coastal waters of the Atlantic Ocean. By early fall in Nova Scotia, with contributions from cool dry air and elevated ocean temperatures, the fog dramatically decreases. During the winter season, poor visibility occurs less than 10 percent of the time and can often be attributed to snow or heavy rain.

A further concern for ships travelling into and out of Chedabucto Bay is the build-up of ice on the ship or any other structures, including the shoreline ("shorefast ice") due to freezing spray. Freezing spray occurs when ocean spray (as a result from increased winds, heavy seas and even the motion of the vessel) spreads over the ship and freezes on point of contact. The typical seasonal range for freezing spray occurs between November and April; however it is highest in February (JWEL 2004).

North westerly or northerly winds generally contribute to freezing spray. When the strong, cold winds are persistent from the northwest, fall and winter temperatures in Nova Scotia can plummet. When air temperatures drop below the freezing point of salt water, i.e. -2°C or lower, freezing spray conditions in seawater can exist.

6.3.4 Regional Ambient Air Quality

6.3.4.1 Overview

Air quality in this region is generally good and the pollutant levels meet national and provincial quality standards and objectives. This can be largely attributed to its small population, small industrial base, and climatic conditions that provide excellent dispersion of air contaminants (NSE 1998). The ambient air quality also benefits from the mixture of relatively clean polar and Arctic air masses. However, on some occasions, there has been a tendency for the long-range transport of air masses, originating in central Canada and the eastern seaboard, to enter into the Nova Scotia area and cause poor air quality conditions. (EC 2014b). Historically, these air

masses have imported gaseous sulphur compounds responsible for acid rain, which has caused considerable degradation to the Province's surface water resources.

The Air Quality Health Index (AQHI) is measured for Halifax, Sydney, Kentville, Greenwood, Pictou, and Port Hawkesbury. The AQHI measures the current levels of outdoor air pollution and related human health risks using a scale of 1 to 10 representing low to very high risk levels. Three air pollutants are measured in order to calculate the AQHI and include ground-level ozone (O₃), particulate matter less than 10-micron in diameter (PM_{2.5}) and nitrogen dioxide (NO₂). The closest monitoring station to the Project site is Port Hawkesbury and the current air quality levels can be viewed online at the Nova Scotia Environment website at www.airhealth.ca.

The Project site is located in a rural setting with little industrial development; the closest industrial development is in Port Hawkesbury approximately 40 km east of the Black Point property. Industrial sites that reside within a 50 km radius include: the Pacific West Paper Mill, Point Tupper Generating Station, ExxonMobil Point Tupper Fractionation Plant, NuStar Terminals hydrocarbon trans-shipping facility and the Goldboro (LNG) gas plant. There is also several mineral extraction and shipping facilities within 50 km of the Project site, including the Martin Marrietta aggregate quarry and marine facility and the Georgia Pacific gypsum load-out facility, both located along the Canso Strait. Aside from this, there are no other anthropogenic sources within 100 km that could negatively affect the ambient air quality.

6.3.5 *Ambient Air Quality Standards*

Nova Scotia Department of the Environment (NSE) has set maximum permissible ground level concentrations for ambient air quality in the province of Nova Scotia (Table 6.3-8).

**Table 6.3-8:
NS Ambient Air Quality Standards**

Contaminant	Averaging Period	Maximum Permissible Ground Level Concentration	
		($\mu\text{g}/\text{m}^3$)	(pphm)
Carbon Monoxide (CO)	1 hour	34,600	3,000
	8 hours	12,700	1,100
Hydrogen Sulphide (H ₂ S)	1 hour	42	3
	24 hours	8	0.6
Nitrogen Dioxide (NO ₂)	1 hour	400	21
	Annual	100	5
Ozone (O ₃)	1 hour	160	8.2
Sulphur Dioxide (SO ₂)	1 hour	900	34
	24 hours	300	11
	Annual	60	2
Total Suspended Particulate (TSP)	24 hours	120	-
	Annual	70	-

Source: Nova Scotia *Air Quality Regulations*, Schedule A.

In 2012, provincial jurisdictions agreed to the implementation of a new air quality management program. The new Canadian Ambient Air Quality Standards (CAAQS) are authorized as new objectives under the Canadian Environmental Protection Act, 1999 (CEPA) and replace the current Canada Wide Air Quality Standards under CCME (2000). Currently, standards for particulate matter less than 2.5-micron in diameter (PM_{2.5}) and ground-level ozone (O₃) have been developed. CEPA is currently working on baseline standards for nitrogen dioxide (NO₂) and sulfur dioxide (SO₂). The CAAQS are voluntary objectives. Table 6.3-9 details the new air quality standards for PM_{2.5} and ozone to be established by 2015 and 2020.

**Table 6.3-9:
Canadian Ambient Air Quality Standards for PM_{2.5} and Ozone**

Pollutant	Averaging Time	Standard 2015	Standard 2020
PM _{2.5}	24- Hour	28 $\mu\text{g}/\text{m}^3$	27 $\mu\text{g}/\text{m}^3$
	Annual	10 $\mu\text{g}/\text{m}^3$	8.8 $\mu\text{g}/\text{m}^3$
Ozone	8-hr	63 ppb	62 ppb

Source: CCME, 2010

6.3.6 Regional Air Quality Baseline

Ambient air quality in Nova Scotia is monitored using a network of 13 sites operated by NSE and Environment Canada through the National Air Pollution Surveillance (NAPS) Network. Motor vehicles, electrical power generation, and pulp and paper processing are the major local sources of air pollutants in the province. Common air pollutants monitored regularly are sulphur dioxide (SO₂), total particulate matter (TPM), PM_{2.5}, particulate matter less than 10 microns in diameter (PM₁₀), carbon monoxide (CO), O₃, and NO₂. There is no air quality monitoring station

in Black Point. The closest NSE monitoring site to the Project site is located in Port Hawkesbury at the old Post Office, approximately 38 km from the site.

The province had an ambient air monitoring station running in the Port Hawkesbury/Point Tupper area, which measured the concentrations of SO₂, Hydrogen Sulphide (H₂S), and TSP. The measured values at these sites were published in 1993 and are presented in Table 6.3-10. The most recent data available for this monitoring station were from a report published by Environmental Canada in August 2013. According to this report, the SO₂ concentrations at the Post Office site were 231 ppb (1-hour max) and 41 ppb (24-hour max) in 2007 (EC 2013a). The proposed Project area, being very much undeveloped, would probably have better air quality and thus less airborne emissions compared to Point Tupper due to Point Tupper's proximity to local industry.

**Table 6.3-10:
Ambient Air Quality at Nearest Monitoring Stations**

	1-Hour Max Concentration	24-Hour Max Concentration	Annual Mean Concentration	Total Number of Exceedances of 1- Hour N.S. Standard
<i>Sulphur Dioxide (SO₂)</i>				
Point Tupper (1993)	538 ppb	196 ppb	8.0 ppb	10
Old Post Office (1993)	100 ppb	23 ppb	4.0 ppb	Not Available
<i>Hydrogen Sulphide (H₂S)</i>				
Point Tupper (1993)	61.8 ppb	16.6 ppb	0.7 ppb	9
<i>Particulate Matter 2.5 microns (PM_{2.5})</i>				
Port Hawkesbury (2013)	Not Available	Not Available	6 ug/m ³	Not Available
<i>Nitrogen Dioxide (NO₂)</i>				
Port Hawkesbury (2013)	Not Available	Not Available	9.4 ug/m ³	Not Available
<i>Total Suspended Particulate (TSP)</i>				
Point Tupper (1993)	Not Available	60 µg/m ³	23 µg/m ³	2
Old Post Office (1993)	Not Available	55 µg/m ³	25 µg/m ³	Not Available

Source: NSDOE 1994 Ambient Air Quality in Nova Scotia (Point Tupper and Old Post Office); Environment Canada 2013 National Air Pollutant Surveillance (NAPS) Monitoring Results 2013 (Port Hawkesbury).

Based on the information above, background concentrations of criteria air pollutants are most likely not exceeding current provincial and national standards at the proposed Black Point Quarry site.

6.3.7 Ambient Noise (Terrestrial and Marine)

The existing terrestrial noise environment has been determined by measurement at two representative geographic locations (one inland, and one nearer the coast). The locations are the residential receptors located nearest to the Property boundary. Noise data were recorded in A-weighted decibels (dBA) and reported in three categories:

1. as equivalent continuous noise level (L_{eq}),

2. as the noise level exceeded for 10% of the time (L_{10}), which is used to give an indication of the upper limit of fluctuating noise, such as that from road traffic; and
3. as the noise level exceeded 90% of the time (L_{90}). This last parameter is generally taken to be the ambient or background noise level.

At both locations, measurements were collected over 1-hour intervals. This data have been collated to report results over the daytime (7am to 7pm), evening (7pm to 11pm), and night-time (11pm to 7am) periods. Time periods corresponding to wind speeds greater than 20 km/h or periods of precipitation have not been included in the summary analysis. The results are summarised in Table 6.3.11.

**Table 6.3-11:
Measured Ambient Noise Levels**

Location	Time Period	Sound Level (dBA)		
		L_{eq}	L_{90}	L_{10}
Location #1 Coastal Half Island Cove Road	Daytime (7am to 7pm)	38.3	27.1	43.2
	Evening (7pm to 11pm)	31.7	28.9	34.4
	Night-time (11pm to 7am)	33.1	28.2	37.0
Location #2 Inland Eagle Valley Road	Daytime (7am to 7pm)	51.0	24.2	56.3
	Evening (7pm to 11pm)	48.9	25.8	53.9
	Night-time (11pm to 7am)	42.1	24.3	35.8

As is expected for a remote rural environment, existing L_{90} background noise levels are very low, below 30 dBA in all time periods at both locations. At each location, little temporal variation was observed in background noise levels throughout the daytime, evening and night-time. The location near the coast had slightly higher background noise levels than the inland location. However, the L_{eq} (or average) noise levels were higher at the inland location, probably due to the influence of road traffic noise.

At the measurement location west of the Project site near the coast, the dominant noise sources noted were natural, including waves, birds, and the movement of leaves. At the location further inland traffic noise from the road was observed, in addition to natural noise sources.

Ambient underwater noise levels in the Project area have not been measured. While there are no existing localised anthropogenic sources, underwater noise can propagate over large distances. For this reason, both natural and anthropogenic sources may contribute to the existing underwater noise environment. Natural underwater noise sources include wind, waves, precipitation, sea ice, marine fauna, and seismic background activity. Anthropogenic noise sources include commercial fishing, shipping, seismic exploration activity, sonar equipment, construction and industrial activity, and distant explosive detonations. Whether natural or anthropogenic sources dominate in the Project area at any particular time and location depends on changing natural conditions, and the proximity and level of the human activities.

Appendix D (Noise and Vibration Technical Report) provides a more detailed description of the existing ambient noise environment. This report also explains the technical terminology used to describe noise levels.

6.3.8 Ambient Light

Given its remote location, there are no existing data sources for summarizing the current light levels in the vicinity of the Project. The Project site is not easily accessible and so transitory ambient light sources from vehicles are rare (from the occasional ATV) to non-existent. Given this, ambient light levels are expected to be minimal and typical of an undeveloped rural area.

The largest artificial light sources in the Project area are the nearest residences on Half Island Cove Road and in Fox Island Main, and vehicle traffic along Highway 16. Additional light originates from passing and anchored ships, which are visible from the shore of the Property. Estimates indicate that 500 – 600 ships traverse Chedabucto Bay annually, not including fishing and recreational vessels (G. Freer, pers. comm. 2014).

6.4 Terrestrial Environment

The description of the terrestrial environment includes habitat, vegetation and wildlife found in the Project site and nearby areas. It also includes birds observed in the marine areas adjacent to the Project site.

Between 2010 and 2014 a number of desk top reviews and field surveys were conducted within the Project area to gather field data for a description of the existing terrestrial environment. The work was carried out in particular to:

- Describe existing habitats and develop a habitat map;
- Confirm, identify, and describe significant habitats including wetlands;
- Delineate and functionally assess wetlands in Project Study Area;
- Identify high potential habitats for rare vascular plant species;
- Determine likely lichen habitat, conduct a rare lichen survey, and evaluated existing habitats for their potential to support rare lichen species;
- Identify and describe indications of previous disturbance; and
- Record (opportunistic) wildlife sightings.

Table 6.4-1 provides a summary of the various terrestrial environment baseline field surveys.

**Table 6.4-1:
Terrestrial Environment Baseline Field Surveys**

Ecological Component	Type of Survey and Information Collected	Survey Date
Vascular Plants	Included species at risk (SAR)/species of conservation concern (SOCC);	June 2010; August 2010; August 2014
	Compiled vascular plant species list for entire Project site	
Lichens	Focused surveys for Species at Risk (SAR)/species of conservation concern (SOCC)	June 2010; August 2014
Birds	Compiled species lists including passerine migration, early and late breeding birds, raptors (owls), early and late shorebird migrants	April 2010; May 2010; June 2010; August 2010; September 2010 January 2011
Mammals	Moose fall rut surveys; general mammal surveys were conducted in conjunction with other taxonomic groups	Targeted survey in September 2014; casual observation as part of various surveys listed in this table

Ecological Component	Type of Survey and Information Collected	Survey Date
Wetlands	Wetland delineations, habitat assessments and functional assessments	August 2010; July 2011; August 2014
Herpetiles	Surveys conducted in conjunction with other taxonomic groups	Part of various surveys listed in this table
Odonates	Compiled lists of species utilizing Project site	June/July 2010; August 2010

Field surveys were supplemented by a review of existing information from various information sources including Species of Conservation Concern (SOCC) databases, federal and provincial government departments and agencies, non- profit groups, internet websites, existing reports and knowledgeable individuals. Specific sources utilized include:

- Atlantic Canada Conservation Data Centre (ACCDC);
- NSDNR;
- NSE;
- NSMNH;
- Canadian Wildlife Service (CWS)/ EC; and
- Other sources as indicated where applicable.

6.4.1 Terrestrial Habitat and Vegetation

The following description of existing terrestrial habitat at the Black Point Project Area is based on observations during field surveys conducted in June 2010, August 2010 and August 2014 as well as compiled data from existing sources.

Ecological Land Classification (ELC) links the abiotic and biotic components of each ecosystem. Climate, landform, and soil influence the distribution of vegetation (NSDNR 2003). ELC therefore provides information on the factors that influence habitats present at the Project site. The site is located in the Acadian Forest Ecozone, the Atlantic Coastal Ecoregion (Ecoregion 8) and the Eastern Shore Ecodistrict (Ecodistrict # 820) (NSDNR 2006). Ecodistrict 820 has an annual precipitation of 1426 mm, a growing season of 195 days, a mean annual temperature of 5.8°C, a mean summer temperature of 14.8°C and a mean winter temp of -3.7°C (NSDNR 2003).

Large portions of the District 820 are covered with forest. The presence of the Atlantic Ocean has more influence on the forests in this ecodistrict than the soils, geology or landform. The ocean provides a consistent coastal climate, resulting in the absence of Red Spruce (*Picea rubens*), Sugar Maple (*Acer saccharum*), White Pine (*Pinus strobus*) and American Beech (*Fagus grandifolia*) in coastal forests. Coastal forest is typically dominated by Balsam Fir (*Abies balsamea*), Black Spruce (*Picea mariana*) and scattered White Spruce. The coastal forests are short lived and usually exist less than 100 years, but the moist climate is conducive to natural regeneration. Typically, most stands of Balsam Fir and Black Spruce have already developed a layer of regeneration while the overstorey breaks up. The influence of the ocean extends inland until it reaches the 60 m contour. Therefore, the Project site is influenced by the ocean (NSDNR 2003).

The Black Point Quarry Project Area encompasses two Ecosections (NSDNR 2006). Ecosection WCKK applies to the western section of the Project Area as well as the northern boundary between the Atlantic coast and the steep cliff. The central and eastern portion of the

Area is classified as Ecosection WCHO. Descriptions of the climatic, geographic and ecological conditions such as disturbance patterns associated with this classification can be found in NSDNR (2003). Ecosections describe the more permanent physical features of topographic patterns, soil texture and soil drainage (NSDNR 2003). Ecosection WCKK indicates well drained, coarse textured soil on hilly terrain. Ecosection WCHO indicates well drained, coarse textured soil on hummocky terrain (NSDNR 2006).

Study Method

In preparation for the vascular plant field surveys, maps of existing habitat were assembled, indicating streams, wetlands and habitats including forest types. A priority species list was prepared prior to conducting field work in order to help guide the plant surveys by identifying plant species at risk /conservation concern potentially present on the site. In order to prepare this priority list an ACCDC data search was obtained to identify any plant species at risk/conservation concern previously identified within 100 km radius of the site.

Surveys within the Project site focused on habitats suitable for potential vascular plant species at risk. Habitats with high potential for species at risk include freshwater and marine wetlands, as well as floodplains of streams and rivers. Forest habitats, except forests in flood plains, are estimated to have medium to low potential for rare vascular plants. Surveys for rare vascular plants were timed to cover both early and late phenology. Further details regarding survey methods and photos are provided in **Appendix E**.

6.4.1.1 Habitat Survey Results

Forest inventory mapping available from NSDNR is based on aerial photography and satellite data. For Guysborough East, which includes the Black Point Quarry site, the mapping used the aerial photography from 1990 to 1998, satellite data last obtained 1999-2002, and treatment data from 2003. The current Forest Inventory Map (NSDNR 2007/2012) was reviewed (NSDNR 2013) and supplemented with field data to prepare a terrestrial habitat map of the Project Area (Figure 6.4-1).

The majority of the Project site consists of a mix of coniferous forest and open/shrub barren vegetation. Vegetation on the Project site remains relatively unaltered with the exception of a few property cut lines, ATV trails and skidder tracks (constructed for underground exploratory testing). A number of treed and open bogs are located on the site while other wetland types present include fen, swamp and marsh. Mixed forests are uncommon but occur in patches on the main portion of the site.

A steep cliff is located near the north end of the Study Area which separates the northern portion from the rest of the Project site. Coniferous forest dominates the cliff and lower north end of the site while a disturbed regenerating forest was also noted in this area as well as a number of wetlands (fen, marsh and bog types). Habitat located immediately adjacent to the coast includes low shrub coastal barrens, rock cliffs, and cobble/boulder/sand beaches.

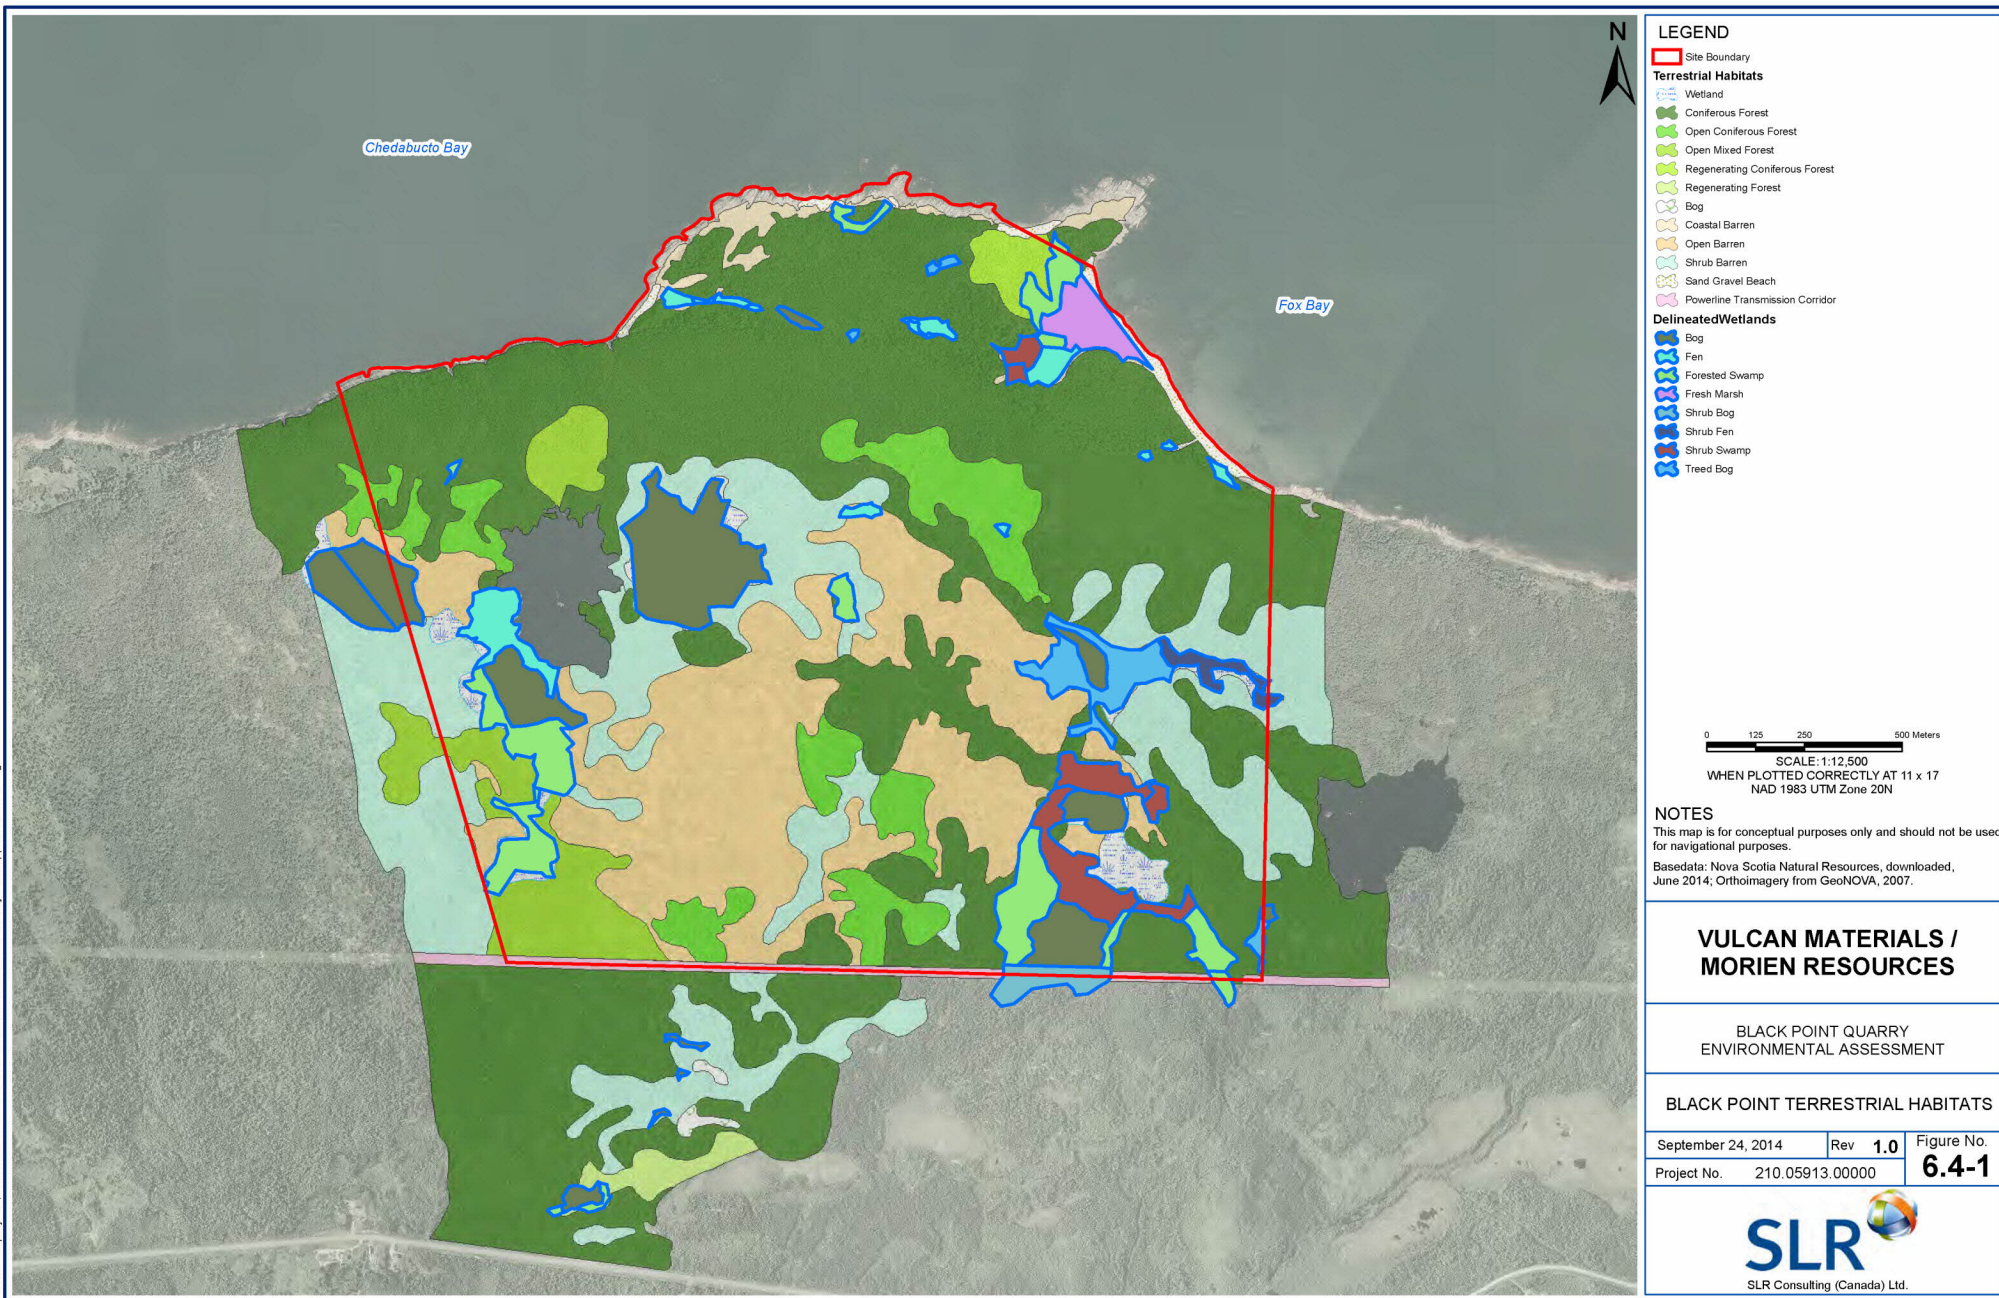

The following description of habitat is based on the most frequent plant species observed in 2014, and tree size where applicable. Seven habitat types and plant communities were identified, including one category of wetlands, containing several wetland classes. The habitat types are summarized in Table 6.4-2. Photos depicting habitat types are provided in **Appendix E**. Photos of wetlands are also provided in the separate wetland survey report (**Appendix F**). A

delineation of habitat types in the Black Point Study Area is shown on Figure 6.4-1 as well as Figure 6.4-2. The individual types are described in more detail below.

**Table 6.4-2:
Habitat Types - Definitions and Summaries**

Picture #	Type	Definition and Summaries
		Forest stands composed of more than 75% coniferous (softwood) trees.
2-1; 2-2	Natural Stand: Coniferous Forest	In the Project footprint, the trees in these polygons are more mature than the trees in "young coniferous forest". Dominated by Black Spruce and Balsam Fir, mature or nearing maturity, with tree diameters for Balsam Fir and Black Spruce from about 15 cm diameter at breast height (dbh ³) to 20 cm and occasionally 30 cm dbh; Red Maple and Heartleaf Birch (<i>Betula cordifolia</i>) are few and up to 20-30 cm dbh.
2-6	Tall Shrubs	At the Project site, tall shrubs with an estimated height of around 2 m, dominated by Huckleberry, Mountain Holly and Pin Cherry. NSDNR categorized this area as "brush", which is defined as any area containing less than 25% merchantable tree cover and contains non-merchantable woody plants consisting of at least 25% cover.
	Young Coniferous Forest	Areas of re-growth, most often following forestry activity, and other disturbance. Dominated by young trees (saplings) with occasional patches of shrubs (often Mountain Holly (<i>Nemopanthus mucronatus</i>), Witherod (<i>Viburnum nudum</i>) or alders (<i>Alnus incana</i>)). Older regenerating forest ⁵ is dominated by young Balsam Fir with an estimated height of 6-10 m.
2-10	Riparian	Habitat along watercourses. In the Project footprint, there is little such habitat. Long stretches of streams have no real floodplain, possibly due to the steep gradient of the terrain.
2-4 ;2-5	Barren	Any area of less than 25% live tree cover containing "ericaceous" vegetation with less than 50% rock out crops and/ or boulder cover and less than 50% other woody plant cover. Area dry and firm in summer. Indicator plants: Bearberry (<i>Arctostaphylos uva-ursi</i>), Rhodora (<i>Rhododendron canadense</i>), Blueberry (<i>Vaccinium</i> sp.), Huckleberry (<i>Gaylussacia</i> sp.) and Lambkill (<i>Kalmia angustifolia</i>).
2-7	Natural Stand: Mixed Forest	Forest stands composed mostly of Balsam Fir, White Birch, Red Maple, and Black Spruce.
See Appendix F	Fresh Water Wetlands	"Any wet area not identified as a lake, river or stream". Encompasses the wetland classes: fen, marsh, swamp, and open water; definition extended to include wetland class bog.

\\h1x1-f61\project\5300 PROJECTS\2014\TV144003 - Black Point Quarry EA Support\CAD\EA Figures\6.4-1.mxd

Coniferous Forest

Coniferous forest is a forest dominated by coniferous trees (greater than 75%). The dominant tree species is Balsam Fir and Black Spruce (occasionally White Spruce closer to the coast). A few Mountain Ash (*Sorbus* sp.), Heart-leaf Birch and Red Maple are scattered throughout. The coniferous forest can be more or less open, resulting in various light conditions. The ground cover is dominated by feather mosses with up to 95% cover (e.g., *Hylocomium splendens*, *Pleurozium shreberi*); other mosses including *Dicranum* sp., *Ptilidium crispum*, and occasionally peatmoss (*Sphagnum* sp.) occur. Sparse patches of terricolous lichens (such as reindeer lichen and related species (*Cladonia rangiferina* (*Cladonia* sp. / *Cladonia* sp., *C. maxima*)) are found infrequently. Herbaceous plants such as Bunchberry (*Cornus canadensis*), Sarsaparilla (*Aralia nudicaulis*), Starflower (*Trientalis borealis*), Twin Flower (*Linnaea borealis*), Canada Mayflower (*Maianthemum canadensis*) Goldthread (*Coptis trifolia*), Common Wood Sorrel (*Oxalis montana*) and ferns (e.g., *Dryopteris* sp., *D. felix femina*, or Bracken (*Pteridium aquilinum*), and in damp areas occasionally Cinnamon Fern (*Osmunda cinnamomea*)) are sparse.

Sheep Laurel (*Kalmia angustifolia*), blueberries (*Vaccinium* sp.), and seedlings or saplings of trees and Witherod contribute to a sparse low shrub stratum. Standing and fallen woody debris occur in many areas. Some patches of open coniferous forest can also have a well developed layer of low shrubs, mostly Lambkill, as well as herbaceous plants and mosses. Local relief in coniferous forests on the Site is generally hummocky.

Young (Regenerating) Coniferous Forest

This habitat type encompasses both younger and older regenerating forests. Regenerating forests are areas of re-growth, usually following apparent clear-cut harvesting or other disturbances. These young forests consist of dense stands or young trees dominated by young trees (seedlings, saplings) and shrubs (often Mountain Holly, Witherod, or Alders). Balsam Fir is the dominant tree species, accompanied by spruce (Black Spruce with some White Spruce), and scattered Heart-leaf Birch, Red Maple, and Mountain Ash. Herbaceous ground vegetation is often sparse due to the density of the woody vegetation. Ground cover consists of patches of conifer needles or patches of feather mosses with bunchberry where there is more. This habitat type is primarily located in the northern end of the Study Area, southwest of Wetland 2 (WL2).

Tall Shrub Habitat

Tall shrub habitat is dominated by tall Huckleberry, Mountain Holly and Witherod, scattered alders and occasionally Rhodora, with scattered tree saplings (Balsam Fir, Black Spruce, Red Maple, Mountain Ash, Heart-leaf Birch). The shrubs are an estimated 2 m or more high, and the tree saplings reach an estimated 4 to 6 m height. Ground cover consists of mosses (e.g., peatmoss (*Sphagnum* sp.) and others such as *Dicranum* sp.), ferns (*Dryopteris* sp., bracken, occasionally Ladyfern (*Dryopteris filix-femina*)), Bunchberry and scattered Sarsaparilla. Low shrubs in the understorey are sparse: Lambkill and Velvet-leaved Blueberry (*Vaccinium myrtilloides*) occur, and occasionally Labrador Tea (*Rhododendron groenlandicum*) and Huckleberry. A few scattered larger trees can be found, e.g., Black Spruce, Larch (*Larix laricina*) Balsam Fir or Heart-leaf Birch with a diameter at breast height (dbh) of an estimated 15 to 20 cm. Tall shrub habitat is located throughout the Study Area however it is the dominant habitat in the central portion.

Barren

Much of the Project Site is dominated by low barren vegetation. This habitat type can either be dominated by shrub species such as huckleberry (*Gaylussacia baccata*), late low blueberry and common juniper (*Juniperus communis*) growing to heights of less than one metre. Other forms of this habitat type are dominated by black crowberry mats growing over rocks. This type of barren is typically located closer to the coast (on headlands), but can occur inland over bedrock outcrops.

Riparian

Riparian habitats are found along the small watercourses throughout the Study Area. There is little such habitat within the Study Area where long stretches of streams have no real floodplain, possibly due to the steep gradient of the terrain and the small size of the streams. Consequently, species composition is often similar to the surrounding habitats. A few submergent aquatic vascular plants such as Burreed (*Sparganium* sp.) were found, e.g., in Wetland 1. A stretch of well-developed riparian habitat was found along the un-named streams associated with Wetland 1 and Wetland 14. These areas are dominated by a thick Sphagnum ground layer, Cinnamon Fern, Balsam Fir and Black Spruce.

Mixed Forest

Mixed forest patches are scattered throughout the Project site. These areas are dominated by canopy species such as red maple (*Acer rubrum*), heart-leaved paper birch (*Betula papyrifera* var. *cordifolia*), balsam fir, and understorey species including lambkill, late low blueberry, twinflower, bunchberry, starflower and wild sarsaparilla (*Aralia nudicaulis*). This habitat type is generally located in the southern end of the Project Site but does occur in patches closer to the coast.

Fresh Water Wetlands

Twenty-two freshwater wetlands were detected during the surveys in August 2010, July 2011 and September 2014. Wetland types encountered within the Project Site include open/treed bogs, fens, and treed/shrub swamps. Wetlands surveyed within the Project Area are described in more detail below in Section 6.4.2 and in the 2014 Wetland Baseline Survey Report (**Appendix F**).

Other Habitat

In addition to the vegetation as described above, the following plant communities were noted during the course of the field surveys. The ocean shoreline vegetation is typical of marine shores and includes Beach Pea, Sea Rocket (*Cakile edentula*), Oysterleaf (*Mertensia maritima*), Seaside Plantain, Scotch Lovage, and Sea Lavender. Seaweeds (*Fucus* sp., *Ascophyllum* sp.) are attached to the rocks in the intertidal and subtidal zone.

6.4.1.2 *Plant and Lichen Species of Conservation Concern (SOCC)*

A total of 189 vascular plant species were recorded during the field surveys conducted in 2010 and 2014. A complete list of plant species recorded for the site is provided in **Appendix E**. No

plant species listed by the Species At Risk Act (SARA) or the Nova Scotia Endangered Species Act (NSESA) was recorded during the field surveys. Two plant species of conservation concern were recorded. Plant and lichen Species at Risk (SAR) and species of conservation concern are discussed further in Section 6.7.

One vascular plant species of conservation concern was detected on the Project site during the June 2010 surveys. Southern Twayblade (*Listera australis*) has an ACCDC rarity rank of S2. This species was encountered along two streams located within the Project Area. One location contained over 40 individuals within a relatively small area whereas only one individual was found at the second location. An additional plant species of conservation concern, Northern Comandra (*Geocaulon lividum* – ACCDC rank S3) was detected during the August 2014 field survey. This species was noted in Wetland 18 (WL18) in the open bog portion of this wetland. Numerous individuals were reported throughout this wetland.

Lichen surveys were conducted within the Project Site in June 2010 and August 2014. A list of species recorded and methodologies are discussed in **Appendix E**. Three lichen species of conservation concern were noted during the 2014 surveys and include: Black-footed Reindeer Lichen (*Cladonia stygia*: ACCDC S2S3; Canadian General Status rank 3), Naked Kidney Lichen (*Nephroma bellum*: ACCDC S3?; Canadian General Status rank 3) and Coastal Bushy Beard Lichen (*Usnea flammea*: ACCDC S2S3; Canadian General Status rank 3). In addition, Angelhair Ramalina Lichen *Ramalina thrausta*, detected in 2010, is still considered a species of conservation concern, with a General Status rank of 3.

6.4.1.3 Indications of Past Disturbance

As discussed above, the majority of the Project site is in a natural state with little evidence of disturbance, except for past clearing on the lower platform where homesteading occurred. Some vegetation cutting has occurred to clear property boundaries and a small number of ATV trails are present on site. Recently a number of skidder trails have been cleared to allow a drill rig access to various test pit locations throughout the site for underground exploratory purposes. There is also some evidence of past tree clearing (indicated by remaining stumps) in various portions of the site.

6.4.2 Wetlands

6.4.2.1 Study Methods

Several definitions of “wetland” exist in literature:

- Lands that are seasonally or permanently covered by shallow water, including lands where the water table is at or close to the surface. The presence of abundant water causes the formation of hydric soils and favours the dominance of either hydrophytic or water-tolerant plants. The five major types of wetlands are: marshes, swamps, bogs, fens and shallow open waters (EC 2013b).
- A wetland is land “where the water table is at, near, or above the surface or which is saturated for a long enough period to promote such features as wet-altered soils and water tolerant vegetation” (EC 1996).
- A wetland is land that is “saturated with water long enough to promote wetland or aquatic processes as indicated by poorly drained soils, hydrophytic (i.e., water-loving) vegetation and various kinds of biological activity which are adapted to a wet environment” (GC 1991).

- Wetlands are areas of “marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six metres” (United Nations Educational, Scientific and Cultural Organization (UNESCO) 1987).

Although each definition is slightly different, the relevant common aspects adopted for the purpose of this report that define a wetland are:

- Land that is saturated or covered by water for some time during the growing season;
- Poorly drained soils; and
- Predominantly hydrophytic vegetation.

Following this definition, wetland determinations were based on the following three criteria:

- Majority of dominant vegetation species are wetland associated species;
- Hydrologic conditions exist that result in periods of flooding, ponding, or saturation during the growing season; and
- Hydric soils are present.

A combination of desktop review and field work was utilized to identify and assess wetland habitat occurring within and/or adjacent to the Project area. Wetland delineations were conducted according to standard methodologies approved by NSE (NSE 2014c). The determination of wetland habitat in the field was based largely on the Corps of Engineers Wetland Delineation Manual (the Manual) (Environmental Laboratory 1987) and the Regional Supplement to the Corps of Engineers Wetland Delineation Manual (US Army Corps of Engineers (USACE), 2012). Functional assessments were conducted using the NovaWET method which has been developed by NSE for the purpose of assessing wetland functions in NS. A field report is presented in **Appendix F** which provides further details related to the methodologies used to delineate and assess all wetlands identified as well as detailed results of the wetland study.

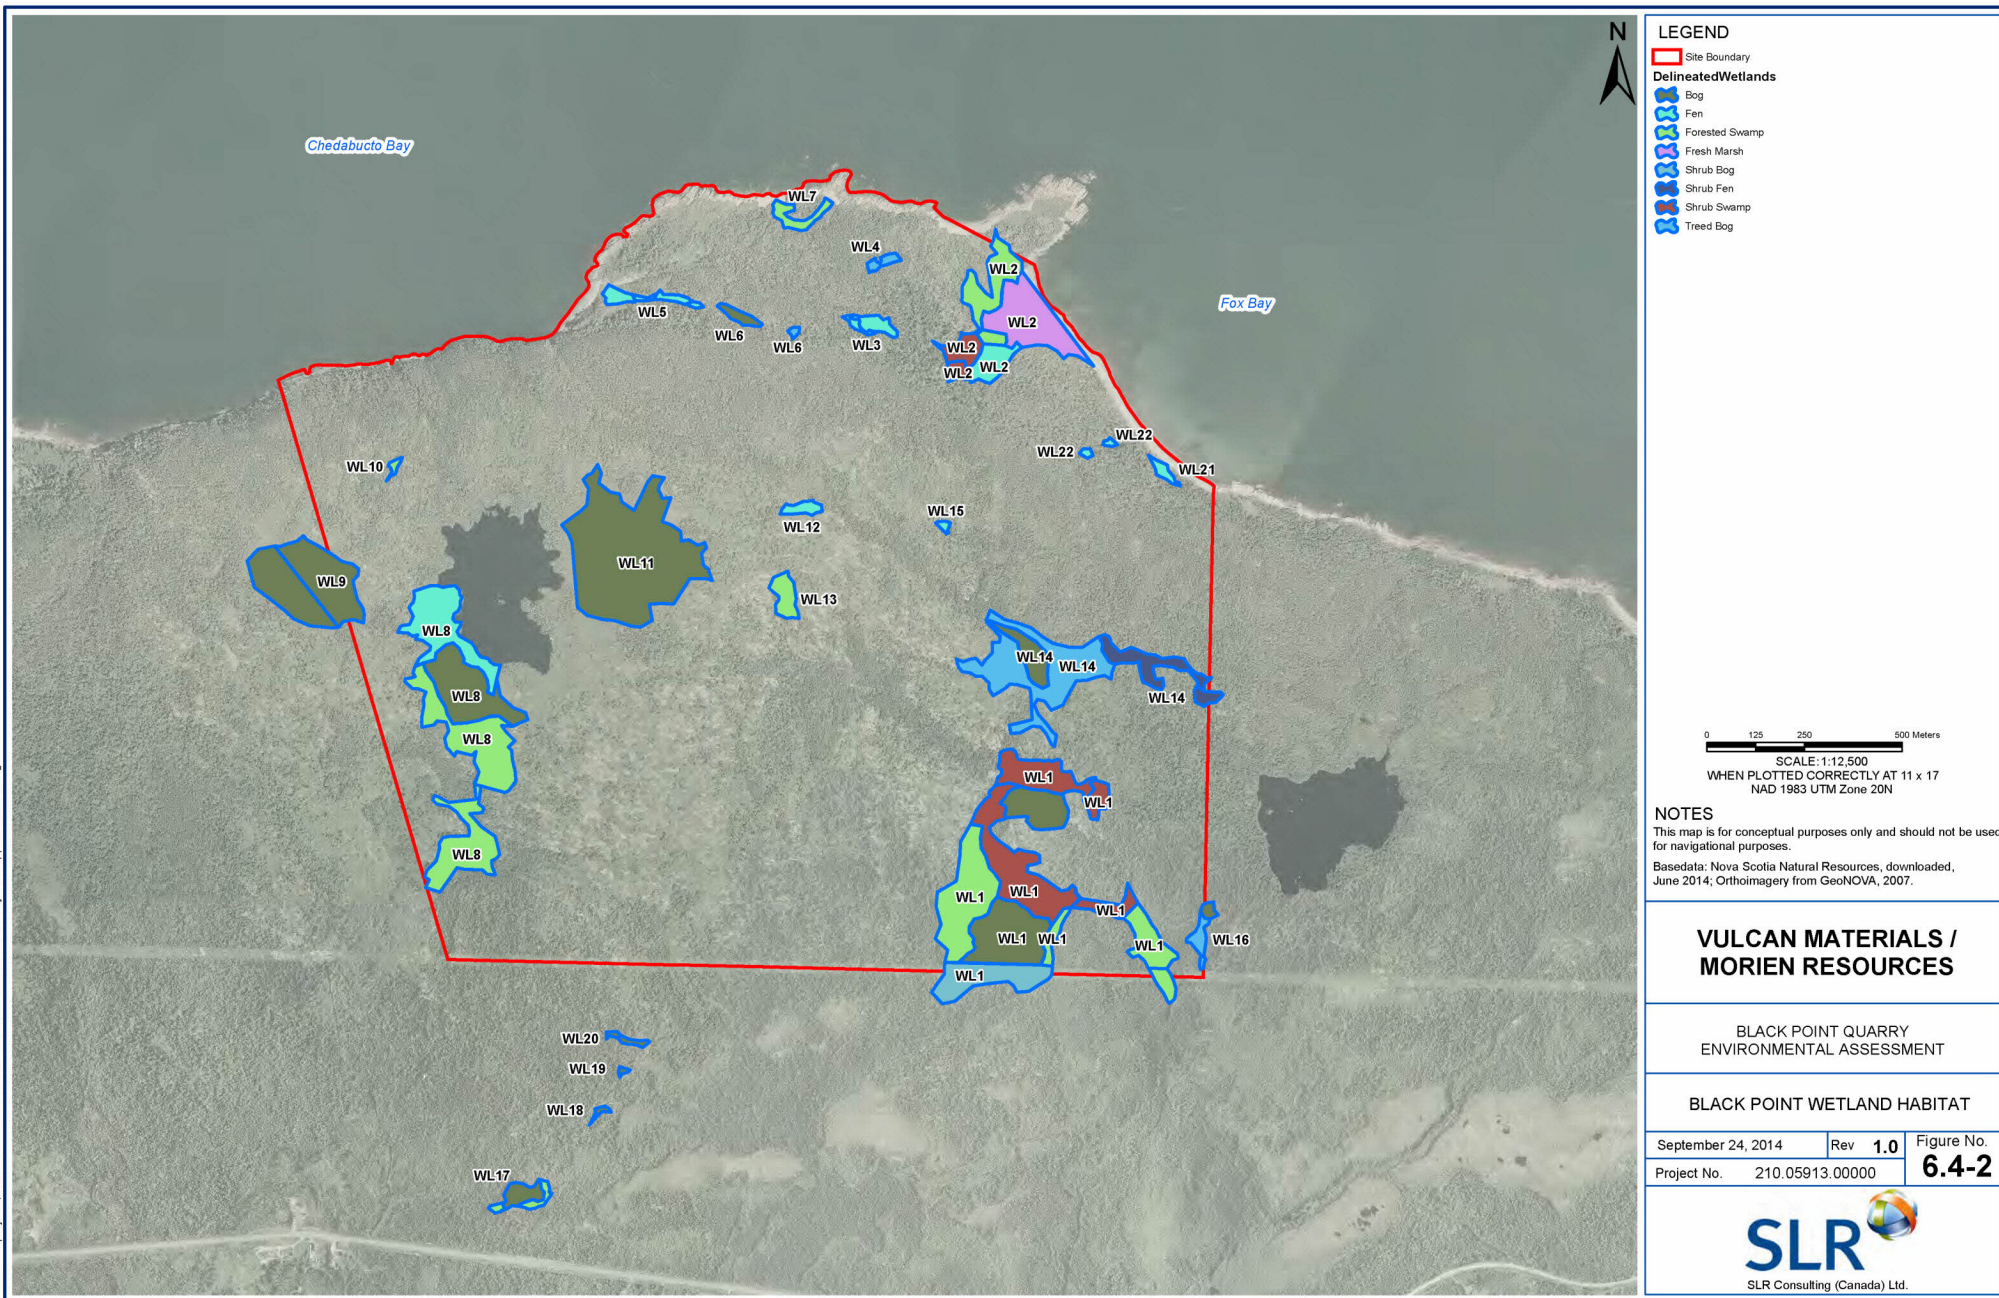

6.4.2.2 *Wetland Survey Results*

A total of 22 wetlands were identified within the Project footprint and/or determined to be hydrologically connected downstream (Figure 6.4-2 and Table 6.4-3). The majority of wetland habitat identified consists of open bogs and riparian fens which range in size from approximately 16.5 ha to <0.5 ha. Other wetland types identified include swamp and marsh as well as complexes including a combination of a number of these wetland types. The total area of wetland habitat identified within the Project Study Area is approximately 57 ha.

Ten (10) of the 22 wetlands surveyed were found to occur directly within the proposed footprint of the Pit, Fill Areas and Plant Location (WL1, WL3 – WL6 and WL11-WL15 inclusive in Table 6.4-3). Four (4) wetlands surveyed were also found to occur within the proposed footprint of the access road (WL12- WL20 inclusive). Seven (7) wetlands surveyed (WL7-WL10, WL16, WL21 and WL2) were found to occur outside the proposed footprint of all Project components however these wetlands may be indirectly impacted by the project and as such were included in the surveys. Complete wetland delineation, habitat assessments and functional assessments were conducted for all 22 wetlands surveyed.

Table 6.4-3 provides a summary of all wetlands assessed along with their general characteristics and corresponding coordinates (UTM Zone 20, NAD 83).

Total Wetland Area (ha)				57.3			

The functional assessments conducted for the 22 wetlands located within the Project site determined that the overall watershed condition within which these wetlands are located is in a relatively unaltered state with wetland habitat covering approximately 11% of the total land area of the watershed. The buffer area surrounding these wetlands is fully vegetated and relatively unaltered providing high quality wildlife habitat and water quality functions. All wetlands assessed were determined to provide high floristic quality where the plant community is composed of native species characteristic of the wetland type with a very minor component of non-native species. Table 6.4-4 presents a summary of the various significant functions for which each wetland was assessed to provide (see **Appendix F** for more details regarding the functional assessments).

**Table 6.4-4:
Wetland Functional Assessment Summary**

Significant Function	WL1	WL2	WL3	WL4	WL5	WL6	WL7	WL8	WL9	WL10	WL11	WL12	WL13	WL14	WL15	WL16	WL17	WL18	WL19	WL20	WL21	WL22

SF29-Rate the wetland's community use/value (H,M,L)	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L	L

Notes:

* SF7/SF25/SF27 is considered a red rated function if a species present is listed by SARA or NSESA as Endangered/Threatened/Special Concern; NSDNR - Red listed; or Ranked by ACCDC as S1

Cells highlighted in red indicate this function is considered to be critical to the watershed or represent a highly degraded watershed. These functions are typically unique or rare or associated with a high risk to the watershed if lost (NSE 2014c).

unless otherwise stated: H=High; M=Moderate/Medium; L=Low; Y=Yes; N=No; NAT=Natural

Wetland 1 (WL1)

WL1 is a fen/bog/swamp wetland complex approximately 16.5 ha in total area located in the southeast end of the Project Area. An un-named stream flows into this wetland from the northwest corner and outlets from the southeast corner. A shrub and treed swamp borders the stream as it flows through the wetland. A power transmission corridor is present along the southern end of this wetland. This wetland may significantly contribute to the maintenance of water flow to the unnamed stream that constitutes the inlet and outlet of this wetland. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was recorded in WL1.

Wetland 2 (WL2)

WL2 is characterized as a wetland complex comprised of marsh, fen and swamp wetland types. This wetland borders a small pond at the northern boundary located behind a barrier beach. Two small unnamed streams enter this wetland on the south side but there is no evidence of an outlet channel. There is evidence that this area does receive periodic salt water influx during storm events (presence of dried seaweed and ocean litter such as lobster traps and buoys) however the vegetation present in this wetland indicate that this is a fresh water pond. This wetland provides a high diversity of habitat that can be utilized by various wildlife species. WL2 may also serve to stabilize the shoreline during storm events.

Wetland 3 (WL3)

WL3 is characterized as a sloped throughflow fen wetland located in the northern end of the Project Area. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. This wetland may significantly contribute to the maintenance of water flow to the unnamed stream that constitutes the inlet and outlet of this wetland which flows east and connects to WL2.

Wetland 4 (WL4)

WL4 is characterized as an isolated treed bog wetland located near the coast in the northern end of the Project Area. Dominant species in this wetland include Cinnamon Fern, Three-seeded Sedge (*Carex trisperma*) and Black Spruce. The land surrounding the wetland is dominated by coniferous forest and is in a natural state and fully vegetated. Although the wetland contains low diversity in terms of species and plant communities, the plant community present is considered of high quality.

Wetland 5 (WL5)

WL5 is characterized as a sloped throughflow fen wetland at the northern end of the Project Area. This wetland contains a mix of herb and shrub dominated areas. The herb fen portions of this wetland are dominated by Cottongrass (*Eriophorum* sp), and Bog Aster (*Oclemena nemoralis*) while the shrub portion is dominated by Alder and Mountain Holy. Broadleaf cattail (*Typha latifolia*) is present within the small stream that flows through this wetland.

Wetland 6 (WL6)

WL6 is characterized as an outflow bog wetland. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. This wetland is important in maintaining stream flow of the unnamed stream that originates from the west and east ends of this wetland. These outflow streams hydrologically connect Wetland 6 to Wetland 5 in the west and WL3 in the east.

Wetland 7 (WL7)

WL7 is characterized as a throughflow swamp wetland which occurs at the forest edge at the northern end of the Project Site. Dominant species in this wetland include Cinnamon Fern, Three-seeded Sedge (*Carex trisperma*) and Black Spruce. The land surrounding the wetland is dominated by coniferous forest and is in a natural state and fully vegetated.

Wetland 8 (WL8)

WL8 is characterized as a wetland complex comprised of a mix of bog, fen and swamp types that follows an un-named watercourse along the western end of the Project Area. This wetland may significantly contribute to the maintenance of water flow to this stream which southwest beyond the Project Area. The Bog Portion of this wetland may also serve as a groundwater recharge site which is based on the lack of perennial outlet channel, type of wetland and conditions of upland soil. Wetland 8 contains a high diversity of plant communities providing habitat to a variety of wildlife species. Two lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) and Coastal Bushy Heard Lichen (*Usnea flammea* – ACCDC rank; S2S3) were recorded in WL8.

Wetland 9 (WL9)

WL9 is characterized as an isolated domed bog wetland located on the western boundary of the Project Area. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. This wetland may serve as a groundwater recharge site which is based on the lack of perennial outlet channel, type of wetland and conditions of upland soil. The plant community in this wetland was determined to be relatively intact with moderate species diversity and little to no influence of invasive/non-native species. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was recorded in WL9.

Wetland 10 (WL10)

WL10 is characterized as a throughflow treed swamp wetland located in the western end of the Project Area. An ATV trail was noted to run through the southern end of this wetland. Although this wetland contains low diversity of plant communities, the community present is of high quality. One lichen species of conservation concern, Naked Kidney Lichen (*Nephroma bellum* – ACCDC rank; S3?) was recorded in WL10.

Wetland 11 (WL11)

WL11 is characterized as a large isolated domed bog wetland located in the central portion of the Project Area near Fogherty Lake. This wetland may serve as a groundwater recharge site. The plant community in this wetland was determined to be relatively intact with moderate species diversity and little to no influence of invasive/non-native species. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was recorded in WL11.

Wetland 12 (WL12)

WL12 is characterized as an outflow bog / fen wetland located in the central portion of the Project Area. A skidder trail has been constructed through this wetland however the integrity of the wetland and surrounding buffer is considered to be high. Although this wetland contains low diversity of plant communities, the community present is of high quality. One lichen species of conservation concern, Coastal Bushy Beard Lichen (*Usnea flammea* – ACCDC rank; S2S3) was recorded in WL12.

Wetland 13 (WL13)

WL13 is characterized as an isolated treed swamp wetland located in a depression in the landscape in the central portion of the Project Area. Vegetation surrounding the wetland consists of a mix of coniferous forest and shrub barren. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated.

Wetland 14 (WL14)

WL14 is characterized as a wetland complex comprised of a mix of bog and fen types. The plant community in this wetland was determined to be relatively intact with moderate species diversity and little to no influence of invasive/non-native species. This complex consists of a number of different wetland types and as such it is considered to have a moderate diversity of high quality vegetation communities. This wetland may significantly contribute to the maintenance of water flow to the unnamed stream that constitutes the inlet and outlet of this wetland which flows to the east eventually into Murphy's Lake.

Wetland 15 (WL15)

WL15 is characterized as a sloped throughflow fen wetland located in a depression in the landscape. A skidder trail is present through the east side of the wetland. A small watercourse flows through this wetland from west to east, eventually connecting to Wetland 14. Vegetation surrounding the wetland consists of a mix of coniferous forest and tall shrub barren. Although this wetland contains low diversity of plant communities, the community present is of high quality.

Wetland 16 (WL16)

WL16 is characterized as an isolated bog wetland. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. This wetland is located at

the eastern boundary of the Project Area. Wetland 16 may serve as a groundwater recharge site.

Wetland 17 (WL17)

WL17 is characterized as an outflow bog / swamp wetland complex located along the proposed access road to the Site. This wetland may significantly contribute to the maintenance of water flow to the unnamed stream that originates from this wetland and extends to the west of the Site. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. Two lichen species of conservation concern, Coastal Bushy Beard Lichen (*Usnea flammea* – ACCDC rank; S2S3) and Naked Kidney Lichen (*Nephroma bellum* – ACCDC rank S3?) was recorded in WL17.

Wetland 18 (WL18)

WL18 is characterized as an isolated bog wetland located along the proposed access road to the Project Site. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. One plant species of conservation concern, Northern Comandra (*Geocaulon lividum* – ACCDC rank; S3) was recorded in WL18. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was also recorded in WL18. This wetland may also serve as a groundwater recharge site.

Wetland 19 (WL19)

WL19 is characterized as an isolated bog wetland located on the proposed access road to the Project Site. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was recorded in WL19. This wetland may also serve as a groundwater recharge site.

Wetland 20 (WL20)

WL20 is characterized as an isolated bog wetland located on the proposed access road to the Project Site. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. One lichen species of conservation concern, Black-footed Reindeer Lichen (*Cladonia stygia* – ACCDC rank; S2S3) was recorded in WL20. This wetland may also serve as a groundwater recharge site.

Wetland 21 (WL21)

WL21 is characterized as a sloped inflow fen wetland located at the north east corner of the Project Area. Although there is no outflow channel present, outflow from this wetland likely occurs under/through the boulder, cobble beach located along the northern boundary of this wetland. An old ATV trail is present through this wetland however there is a second more recently used trail travelling around the wetland indicating that users are now avoiding the wetland. The plant community in this wetland was determined to be relatively intact with

moderate species diversity and little to no influence of invasive/non-native species. Although this wetland contains low diversity of plant communities, the community present is of high quality.

Wetland 22 (WL22)

WL22 is characterized as a sloped throughflow fen wetland located at the north east end of the Project Area. The integrity of this wetland and surrounding buffer is considered to be high where impacts to this wetland are minimal and the adjacent buffer area is considered to be in a natural state and fully vegetated. This wetland consists of two open fen portions connected by a small watercourse. Although this wetland contains low diversity of plant communities, the community present is of high quality.

6.4.3 Terrestrial Wildlife

Important Terrestrial Fauna Habitats

Significant habitats include sites where SAR or species of conservation concern occur, habitats that are rare in NS, and sites where unusually large concentrations of wildlife occur (NSEL 2009). The NSDNR maintains a Significant Species and Habitats (SigHab) database (NSDNR 2012a), which in addition to sites described above may also report habitats that are critical for species that are not rare but are valued by humans, or are sensitive to human developments.

The NSDNR (SigHab) database (NSDNR 2012a) was reviewed in order to obtain a complete list of significant habitats identified within 100 km of the Project footprint. It should be noted, however, that this database may not be comprehensive or up to date for the Project area. A total of 956 significant habitat polygons (identified by unique site ID numbers) are located within 100 km of the proposed Project site, including:

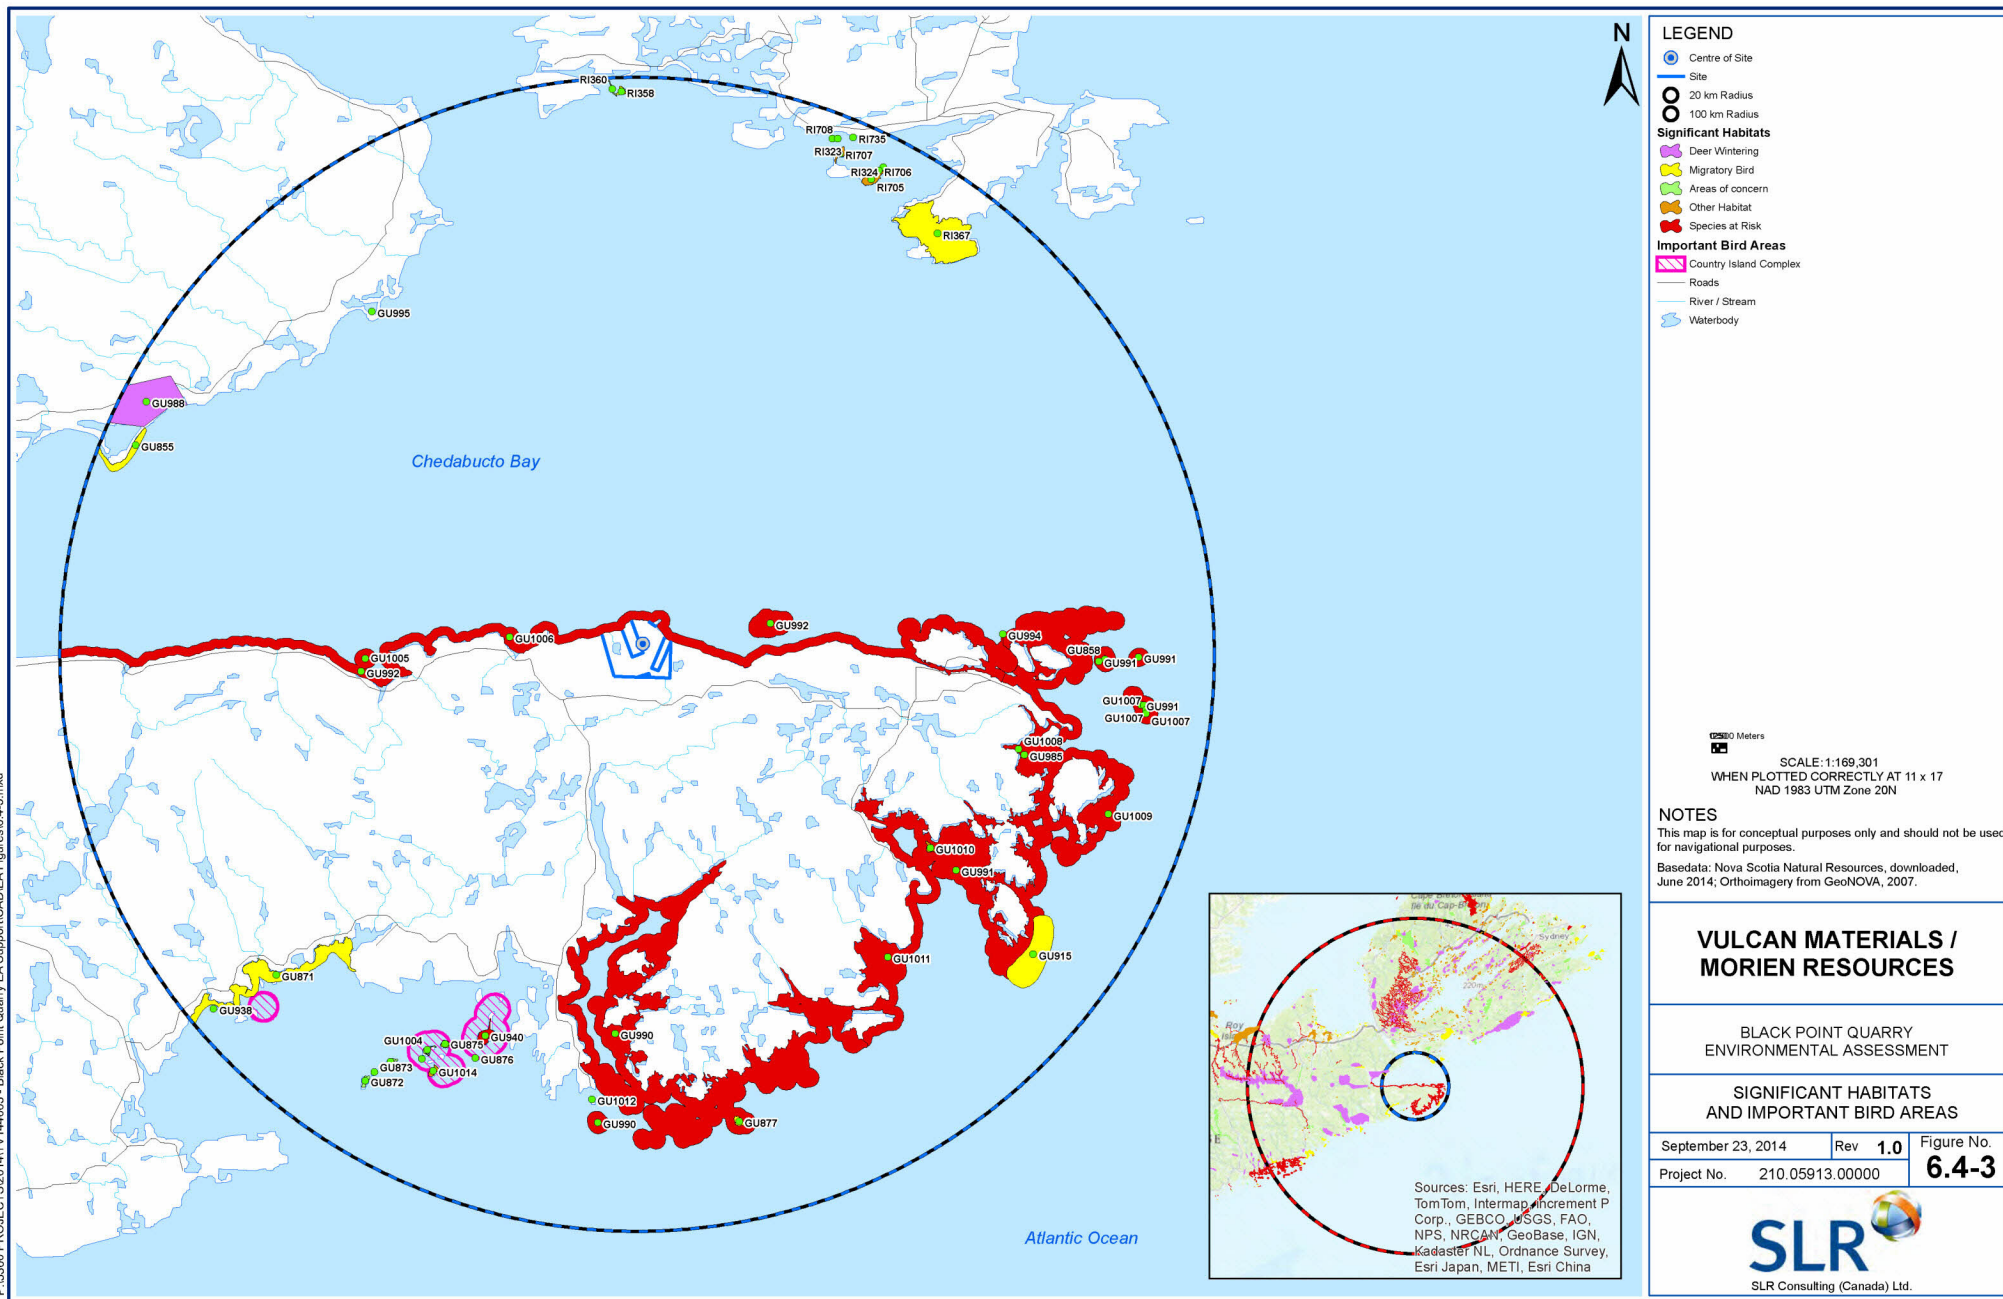

- 170 deer wintering areas;
- 127 migratory bird areas;
- 193 areas with species of concern;
- 39 areas for SAR; and
- 427 areas considered “other habitats”.

Forty-one of these significant habitats are located within 20 km of the Project site (Figure 6.4-5), only one (for Harlequin Duck) overlap with the Project site. Almost half of the significant habitats (18) are areas with avian species of concern; the others are migratory bird areas (10), areas with avian SAR (4), deer wintering areas (1), and “other habitats” (8) which include important habitats for Common Eider and nesting areas for raptors or colonial species.

**Table 6.4-5:
Significant Habitats Within 20 km of the Project Site**

Site #	Type	Primary Species	Approximate Location in relation to Project area
RI360	Species of concern	Common Tern	Across Chedabucto Bay, approximately 19 km to the north.
RI358	Migratory bird	Common Eider	Across Chedabucto Bay, approximately 19 km to the north.
RI323	Migratory bird	Double-crested Cormorant	Across Chedabucto Bay, approximately 18.7 km to the northeast.
RI324	Species of concern	Common Tern	Across Chedabucto Bay, approximately 18.5 km to the northeast.
RI367	Migratory bird	Whimbrel	Across Chedabucto Bay, approximately 16.5 km to the northeast.
GU855	Migratory bird	Unspecified	Across Chedabucto Bay, approximately 18.8 km to the west-northwest.
GU858	Migratory bird	Unspecified	Located 16.0 km to the east.
GU915	Migratory bird	Common Eider	Nearest point is 16.4 km to the south-southeast.
GU875	Migratory bird	Common Eider	Nearest point is 15.5 km to the south-southwest.
GU874	Species of concern	Common Eider	Nearest point is 16.9 km to the southwest.
GU876	Other habitat	Significant area	Located 15.5 km to the south-southwest.
GU873	Species of concern	Common Eider	Located 17.5 km to the southwest.
GU872	Species of concern	Common Eider	Nearest point is 17.9 km to the southwest.
GU877	Migratory bird	Common Eider	Nearest point is 16.9 km to the south-southeast.
GU938	Species of concern	Roseate Tern	Located 19.5 km to the southwest.
GU940	SAR	Tern (unclassified)	Nearest point is 14 km to the south-southwest.
GU985	Other habitat	Bald Eagle	Located 13.8 km east of the site.
GU871	Migratory bird	Waterfowl	Nearest point is 15.5 km to the southwest.
GU988	Deer wintering area	White-tailed Deer	Nearest point is 19 km to the west-northwest, across Chedabucto Bay.
RI705	Other habitat	Common Eider	Across Chedabucto Bay, approximately 18 km to the northeast.
RI706	Other habitat	Common Eider	Across Chedabucto Bay, approximately 18.3 km to the northeast.
RI707	Other habitat	Common Eider	Across Chedabucto Bay, approximately 18.3 km to the northeast.
RI708	Other habitat	Common Eider	Across Chedabucto Bay, approximately 18.8 km to the northeast.
GU990	SAR	Harlequin Duck	Nearest point is 7.6 km to the south-southeast.
GU991	SAR	Harlequin Duck	Nearest point is 9.2 km to the east.
GU992	SAR	Harlequin Duck	Extends along part of the coast of the Canso peninsula, including the northern edge of the Project area.
GU994	Migratory bird	Double-crested Cormorant	Located 12.5 km to the east.
GU995	Species of concern	Tern (unclassified)	Located 14.8 km to the northwest, across Chedabucto Bay.
GU1002	Species of concern	Tern (unclassified)	Located 16.3 km to the south-southwest.
GU1004	Species of concern	Tern (unclassified)	Located 15.9 km to the south-southwest.
GU1005	Species of concern	Tern (unclassified)	Located 9.6 km to the west.

Site #	Type	Primary Species	Approximate Location in relation to Project area
GU1006	Species of concern	Tern (unclassified)	Located 4.6 km to the west.
GU1007	Species of concern	Tern (unclassified)	Nearest point is 17.5 km to the east.
GU1008	Species of concern	Tern (unclassified)	Located 13.5 km to the east.
GU1009	Species of concern	Cormorant (unclassified)	Located 17.2 km to the east.
GU1010	Other habitat	Great Blue Heron	Nearest point is 12.2 km to the southeast.
GU1011	Species of concern	Tern (unclassified)	Located 13.8 km to the southeast.
GU1012	Species of concern	Tern (unclassified)	Located 15.9 km to the south.
GU1013	Species of concern	Tern (unclassified)	Located 16.3 km to the south.
GU1014	Other habitat	Great Blue Heron	Nearest point is 16.5 km to the south.
RI735	Species of concern	Tern (unclassified)	Across Chedabucto Bay, approximately 19 km to the northeast.

One significant habitat was located along the northern coast of the Project footprint, Site # GU992 - SAR (Harlequin Duck). Harlequin Duck (NSES: Endangered; SARA: Special Concern) are most often found along the coast of NS from November to April, where they congregate in coastal waters along turbulent rocky shores to feed (EC 2007).

Areas of particular importance to the survival of bird species may be given the designation of Important Bird Area (IBA). The IBA program is coordinated by BirdLife International, and administered in Canada by the Canadian Nature Federation and Bird Studies Canada (IBA 2014). The criteria used to identify important habitat are internationally standardized, and are based on the presence of species at risk, species with restricted range, habitats holding representative species assemblages, or a congregation of a significant proportion of a species' population during one or more season. These criteria are used to identify sites of national and international importance.

There is only one IBA located within 25 km of the Project area, the Country Island Complex (NS028), located in Country Harbour and Tor Bay. The Country Island Complex includes Country Island, Goose Island, an unnamed island off Charlos Cove, a peninsula at Fisherman's Harbour, Inner West Bird Island, and three sites in Tor Bay (Cooks, Dorts, and Hog Islands), and its nearest point is approximately 13 km from the Project area to the southwest. Each of these sites supports or has previously supported nesting Roseate Terns, with the largest number found on Country Island (IBA 2014). In 2000, 54 nests were recorded in the Country Island Complex (IBA 2014), although in 2014, just 15 pairs were reported (J. Rock, pers. comm. 2014). The complex also supports a globally significant colony of Leach's Storm-petrel (*Oceanodroma leucorhoa*) (IBA 2014).

Marine traffic associated with the quarry involves at maximum about two bulk carriers visiting the site per week. These vessels will travel within existing commercial shipping lanes, which pass to the south of the South Shore (Port Joli sector) IBA (NS004) near the town of Liverpool. This IBA includes four designated Migratory Bird Sanctuaries (Port Joli, Port Hebert, Sable River and Haley Lake) and provides a variety of coastal habitats including tidal rivers and estuaries, mud or sand flats, open seas, inlets, coastal cliffs and rocky shores (IBA 2014). Nationally significant numbers of Piping Plover (SARA and NSES: Endangered) have nested in this IBA, and during fall migration, large numbers of shorebirds including Black-bellied Plover, Willet, Least Sandpiper, Semipalmated Sandpiper, and Pectoral Sandpiper, feed on the tidal flats. In the winter months, large numbers of waterfowl including Canada Goose, American Black Duck, and Harlequin Duck are present (IBA 2014).

Vertebrates

Birds

Most birds are protected under the MBCA, while others (including raptors, non-migratory game birds, and kingfishers) are regulated under the NSWA. In order to obtain site-specific information on bird species in the Project area, avian field surveys were conducted at the site in 2010 and 2011, and supplemental avian observations on the Project site were made during the September 2014 moose survey.

Field surveys for birds were carried out at those times of the year when birds make the most intensive use of the area; details of the survey methodologies can be found in **Appendix E** (AMEC 2010 surveys) and **Appendix G** (AECOM 2011 winter bird surveys). Survey times were

chosen based on known breeding and migration periods, and all habitats used by the targeted birds were surveyed at appropriate times of the year to maximize the quality and quantity of data obtained. Surveys were conducted at the time of day with the highest likelihood of detecting the target species (e.g., early morning for breeding passerines, and during the appropriate parts of the tidal cycle for shorebirds), and in favourable conditions to maximize detection probability (low winds, no precipitation). Survey dates and primary targets were as follows, and the survey locations are provided in Figure 6.4-4.

- April 14th, 2010: year-round residents and early breeders, including owls;
- May 18th and 19th, 2010: main passerine migration and early breeders;
- June 22nd and 23rd, 2010: main passerine breeding;
- August 25th, 2010: shorebird migration;
- September 23rd, 2010: late shorebird migration; and
- January 18th and 19th, 2011: winter bird species.

Results were obtained for the Second Maritimes Breeding Bird Atlas for the 10 km by 10 km Atlas square which includes the Project area (MBBA 2014). Breeding evidence was recorded for 43 species in Square 20PR42, including four confirmed breeding and 12 considered to be probably breeding based on observed evidence (**Appendix E**). Data were obtained for the Audubon Christmas Bird Count (CBC) in the Strait of Canso, which is the count location nearest the Project area, centred approximately 30 km to the northwest (National Audubon Society 2014). A total of 116 species have been identified in the 17 years of Christmas Bird Counts for which data were available (1995 - 2012; see **Appendix E**). Additional information on bird species in the general Project area was obtained from the ACCDC, Important Bird Areas (IBA) of Canada website, and through information requests from EC-CWS and NatureCounts.

Species Protected under *Nova Scotia Wildlife Act* (NSWA)

Raptor and owl species reported during 2010 and 2011 field surveys of the Project site include Barred Owl, Northern Saw-whet Owl, Bald Eagle, American Kestrel, Merlin, Northern Harrier, Red-tailed Hawk, Sharp-shinned Hawk, and an Osprey was observed in the Project area in 2014. In addition to owls and raptors, Belted Kingfisher, Spruce Grouse and Ruffed Grouse were observed during the 2010-2011 field surveys (**Appendix E**). All of these species are considered possibly breeding in the Project area.

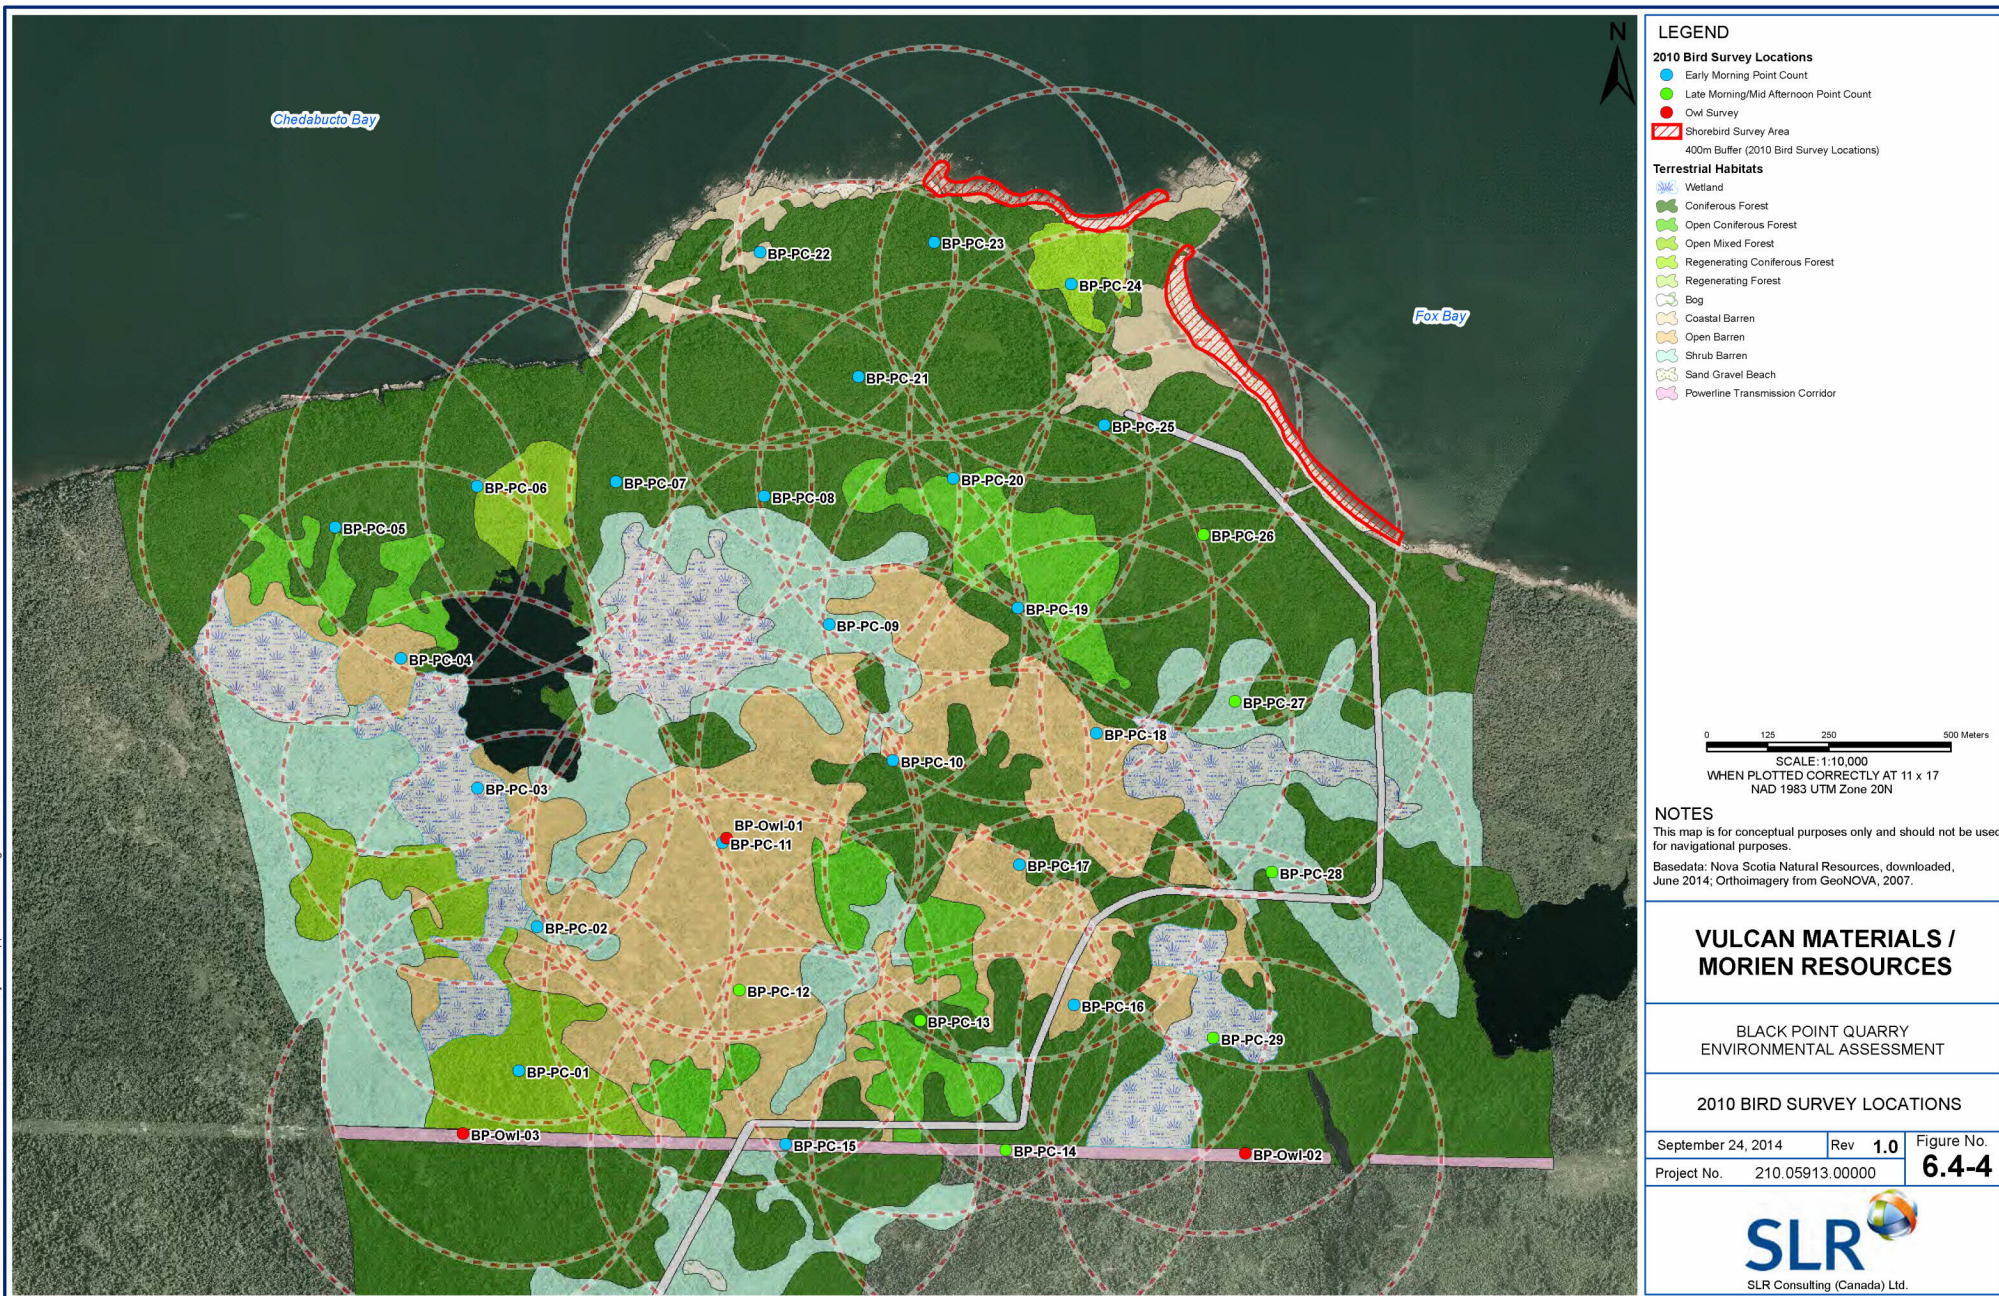

Short-eared Owl and Long-eared Owl were both reported within 100 km of the Project area according to ACCDC (2010), although only the former has potential to breed in the Project area based on available habitat. Broad-winged Hawk, Rough-legged Hawk and Northern Goshawk have each been reported on one occasion in the Strait of Canso Christmas Bird Count (**Appendix E**). NSDNR reports a significant habitat for Bald Eagle 13.8 km east of the Project area (Table 6.4-5).

Migratory Birds Protected under the MBCA

Most species of migratory birds, including passerines, waterfowl, shorebirds and seabirds, are protected under the MBCA. These groups are discussed in turn below.

Landbirds

During June 2010 breeding bird surveys conducted in the Project area, a total of 39 species of migratory landbirds (including passerines, woodpeckers and unclassified species such as hummingbirds) were observed to be possibly breeding in the Project area, including sparrows, finches, thrushes, kinglets, vireos, and numerous warbler species (Table B.1-2 in **Appendix E**). An additional 11 confirmed or potentially breeding species were not observed in the Project area during the breeding season, but reported in the MBBA square in which the Project is located (MBBA 2014); these include Tree Swallow, Bank Swallow, Barn Swallow, Blue Jay, Common Grackle, Cedar Waxwing, European Starling, Fox Sparrow, Mourning Dove, Red-eyed Vireo and Tennessee Warbler (**Appendix E**) The Common Nighthawk was not observed.

In May 2010, 39 species of migrating passerines were observed, while in fall (August and September) 2010, 15 passerine species were noted (Table B.1-1 and Table 3.3 in **Appendix E**).

In the Project area, early spring 2010 and winter 2011 surveys yielded a few common resident landbird species (Table 3.1 in **Appendix E**). Other potential wintering landbird species in the area may be found in the Strait of Canso CBC results (**Appendix E**).

Shorebirds

Overall, the eastern shore of NS does not support large numbers of migrating shorebirds, and only small numbers of shorebirds were observed during the fall surveys at the Project area. A total of five species of shorebirds were found during the 2010 field surveys, all along the sand/gravel beach during the fall migration period (**Appendix E**). Two of those species, the Greater Yellowlegs and Spotted Sandpiper, have potential to breed in the project area, although no evidence of breeding was noted. Fogherty Lake does not appear to provide good breeding habitat for these species, as the bank vegetation is dense and shrubby, and there are no shallow areas for wading.

The barrens habitat present on the Project site provides potential stopover habitat for species such as Whimbrel. In September 2014, two days of surveys were conducted, primarily in the open barrens and wetland habitats, for Mainland Moose (see Appendix N Attachment F for geographical coverage). These surveys included recording of any shorebird sightings. However, no Whimbrel was observed; the timing of these surveys was not optimal for Whimbrel, which is most abundant in the area in July and August, but is known to occur as late as October. In the August 2010 shorebird surveys, observations along the coastline as well as on the site (primarily around Fogherty Lake) were conducted, and again, no Whimbrel were observed; nonetheless, it is possible that they are present at and near the Project site in the late summer and early fall.

The Atlantic Canada Shorebird Survey (ACSS) database provides records of 7 shorebird species from a single survey on 15 August 1979 of several beaches between Port Shoreham and Hadleyville, west of Boyleston and across Chedabucto Bay from the Project area. A total of 4 Black-bellied Plovers, 14 Semipalmated Plovers, 1 Greater Yellowlegs, 1 Willet, 2 Least Sandpipers, 16 Ruddy Turnstones and 17 Spotted Sandpipers were reported (Bird Studies Canada 2015).

No shorebirds were observed in the MBBA in Square 20PR42, which includes the Project Site. The American Oystercatcher nests on Grassy Island, approximately 12 km east of the Project area near the town of Canso; this is one of only two known nesting sites in Canada for the American Oystercatcher, a species that suffered large declines in the early 20th century (EC-CWS pers. comm. 2014). Purple Sandpiper has been reported in the general area in the Strait of Canso CBC (**Appendix E**) as well as during winter waterfowl surveys conducted by EC-CWS (A. Hicks, pers. comm. 2014); this species breeds in the Arctic, but regularly occurs in NS in the winter months, when it feeds along rocky coastlines.

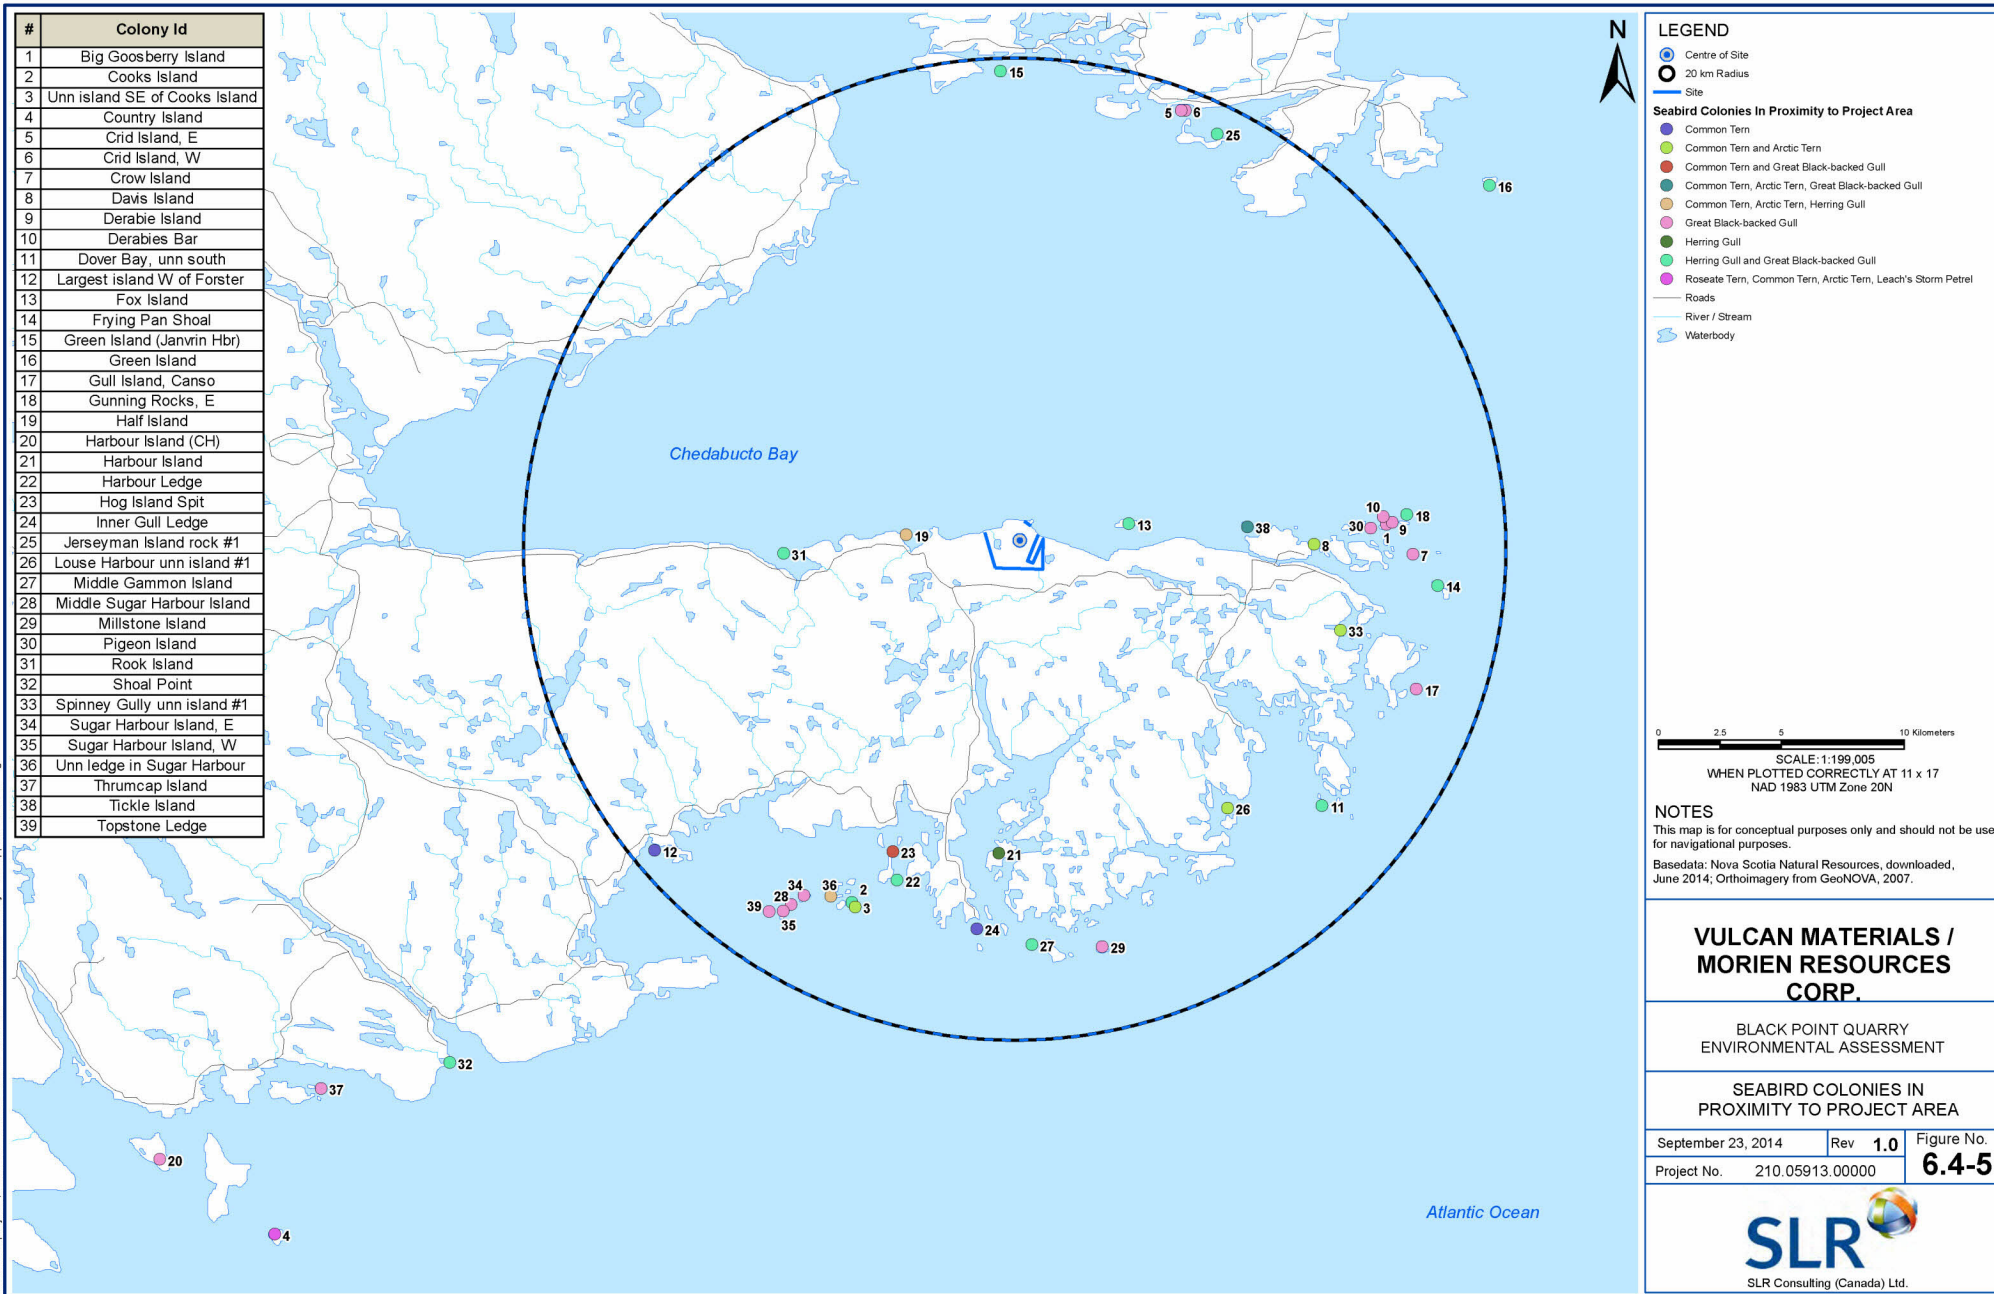

Seabirds and Waterfowl

During field surveys conducted at the site, a total of 12 species of seabirds and waterfowl were observed in coastal environments at or near the Project area, including three gull species, two

cormorant species, four ducks, Common Loon, Northern Gannet and Horned Grebe (**Appendix E**). No breeding evidence for any of these species was observed.

In the MBBA, confirmed breeding was reported in Square 20PR42 for Common Eider and Great Black-backed Gull, and evidence of breeding was reported for Black Guillemot, Common Tern, Herring Gull, Red-breasted Merganser and Common Loon (**Appendix E**). A total of 39 seabird colonies have been identified in the vicinity of the Project area (EC-CWS 2014); these are illustrated on **Figure 6.4-5**. The largest, Country Island, is situated approximately 40 km southwest of the Project sites and supports approximately 1500 nesting pairs of terns including Common, Arctic and Roseate Tern, as well as a large colony of Leach's Storm Petrels (approximately 12,000 pairs). Black Guillemot and Common Eider also nest on Country Island, although numbers of breeding pairs are not provided (Rock and Shervill 2012). The other colonies support large gulls (Herring and Great Black-backed), Common Terns and Arctic Terns; the nearest such colonies are Half Island to the west and Fox Island to the east, each approximately 3 km from the Site.

\\h1x1-fs1\project\5300 PROJECTS\2014\TV144003 - Black Point Quarry EA Support\CAD\EA Figures\6.4-5.mxd

Results of winter surveys for waterfowl conducted by NSDNR and EC-CWS between 1992 and 2011 were obtained from EC-CWS. In Survey Block 226, which extends from approximately the mouth of Guysborough Harbour to the town of Canso and encompasses Black Point, Common Eider, American Black Duck, Common Goldeneye, Long-tailed Duck, Common Loon, mergansers, and scoters are observed most years. Canada lies at the northern edge of the wintering ranges for Surf Scoter, Black Scoter and White-winged Scoter, and while little information exists on the winter distributions of these species, it is likely that most individuals overwintering in Canada likely do so along the eastern shore of Nova Scotia (EC-CWS pers. comm. 2014). Unidentified cormorants, Bufflehead and Mallard have occasionally been observed; the cormorants are likely to be Great Cormorant, which is more abundant in the area during the winter months. Brant and Harlequin Duck were each reported on a single occasion. "Unidentified Goldeneye" has been reported in some survey years; these are likely to be Common Goldeneye but could potentially include Barrow's Goldeneye as well. Waterfowl density in Block 226 is relatively low compared to the adjacent Block 225 that extends from Canso to Dover Island and includes numerous small offshore islands off Canso at the mouth of Chedabucto Bay where thousands of Common Eiders are regularly seen in the winter surveys (A. Hicks, pers. comm. 2014). Other potential wintering seabird species in the area may be found in the Strait of Canso CBC results (**Appendix E**).

EC-CWS (pers. comm. 2014) provided further information on distribution and abundance of Common Eiders along eastern Nova Scotia during winter of 2012 (**Figure 6.4-6**), and stated that significant numbers of eiders are also known to moult along the east coast of Nova Scotia. During this moulting period, which occurs in late August to September for breeding females and June to July for immature, adult males and non-breeders (Goudie *et al.* 2000), birds are flightless and are highly vulnerable to oiling and very sensitive to disturbance. It is not known whether eiders moult in the Project study area.

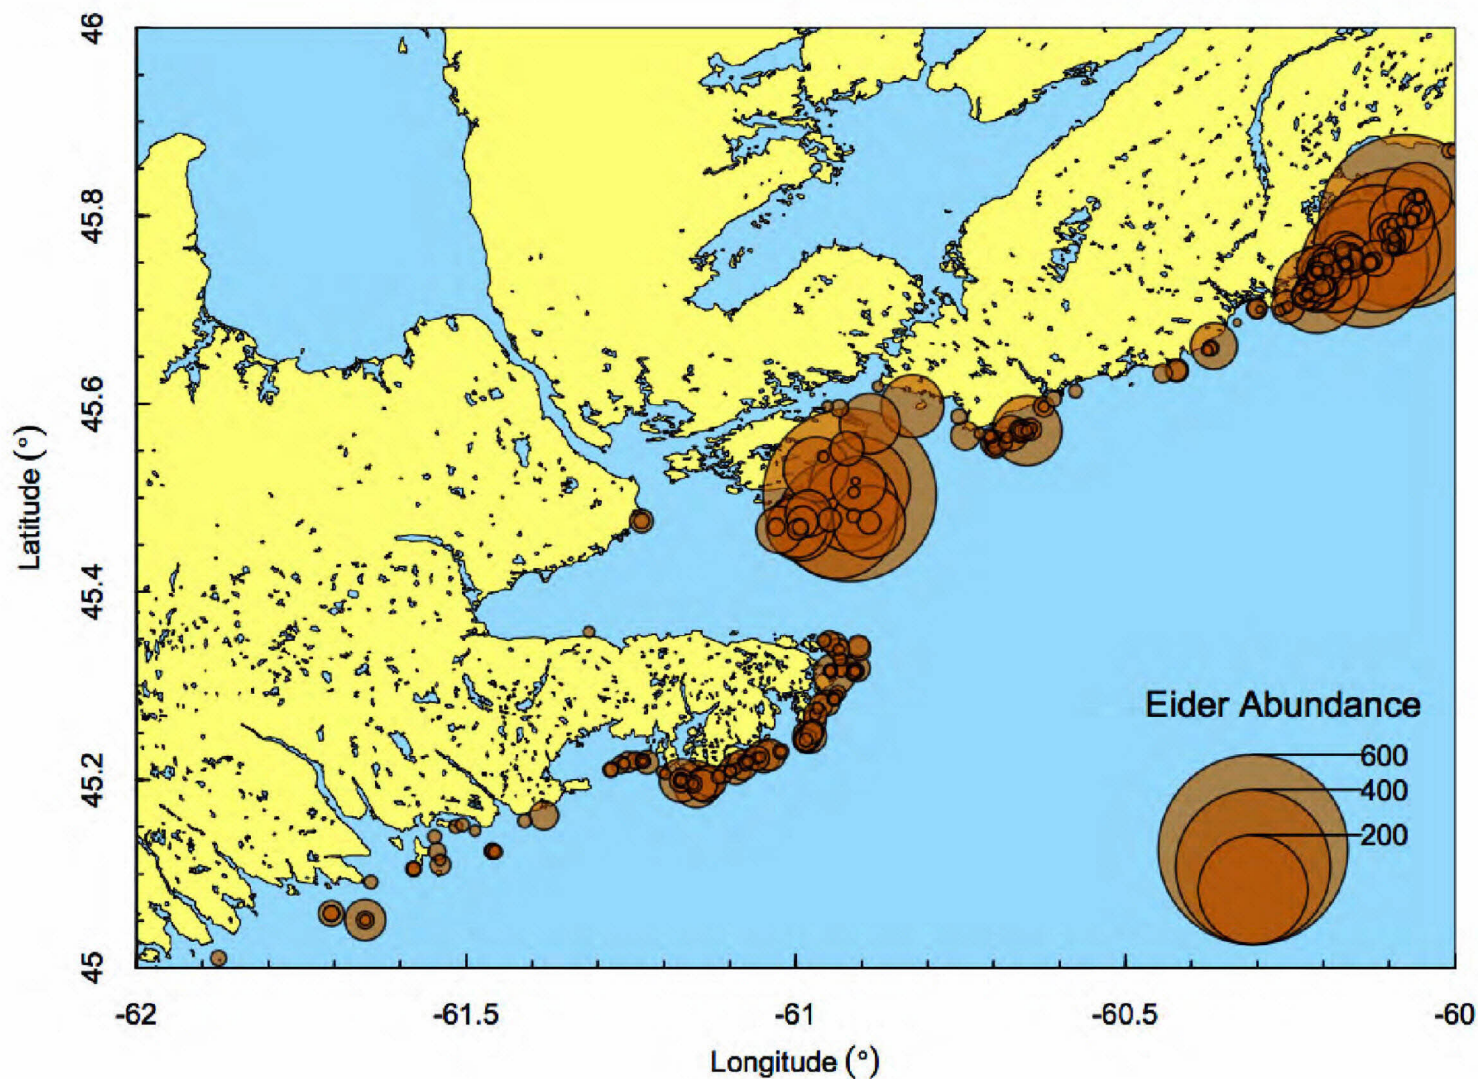

The main overwintering site for the estimated 1100 to 1200 Harlequin Ducks that overwinter in Nova Scotia is located more than 100 km southeast of the Project site within the Eastern Shore Islands Wildlife Management Unit, but some Harlequin Ducks do winter in and near Chedabucto Bay (Soulliere and Thomas 2009). Little information exists on Harlequin Duck spring and fall use of the eastern shore of Nova Scotia, but large numbers of birds have been detected at times, which are assumed to be migrants (Soulliere and Thomas 2009). In the Chedabucto Bay area, Harlequin Ducks have been reported during fall migration, but not during spring migration (Soulliere and Thomas 2009). However, surveys conducted in May and early June of 2014 have detected significant numbers of Harlequin Ducks among offshore islands of the Eastern Shore in the Bay of Islands (Simon 2014), and it is believed that similar searches would likely detect spring migrants within the Project study area (EC-CWS pers. comm. 2014).

EC-CWS initiated the Eastern Canadian Seabirds at Sea (ECSAS) program in 2006 to monitor seabird species at sea. Available data from between 44°N and 46°N and 59°W and 62°W were obtained from EC-CWS; with only three ECSAS surveys conducted in this general area (in early July of 2007, 2008 and 2011), data are relatively scant (C. Gjerdrum, pers. comm. 2014). Nonetheless, they provide some general information on species presence in the area. Sightings in this broad area of interest included Great Shearwater and Sooty Shearwater, Black-legged Kittiwake, Northern Fulmar, Northern Gannet and Wilson's Storm-petrel (ECSAS 2014). None of these species nest in or near the Project area (EC-CWS 2014), and they are highly pelagic outside of the breeding season, and so are highly unlikely to occur in the Project area, other than possibly along shipping routes.

Common Eiders 3 March 2012

Mammals

Throughout the field surveys conducted in the site in 2010 and 2014 by AMEC, and in 2011 by AECOM, evidence of mammal species presence such as sightings, tracks, vocalizations, tufts of hair, scat, and skeletal remains was recorded. Eleven terrestrial mammal species were observed by sight or sign in the Project area during the field surveys; a list of these species including one non-terrestrial species (the Gray Seal) is presented in Table 6.4-8. In addition to these, an unidentified vole was observed during the January 2011 AECOM surveys.

**Table 6.4-6:
Terrestrial Mammal Species Identified in Project Area**

Common Name	Scientific Name	Evidence
Red Squirrel	<i>Tamiasciurus hudsonicus</i>	Sighting, vocalizations
Eastern Chipmunk	<i>Tamias striatus</i>	Vocalizations
American Beaver	<i>Castor canadensis</i>	Dams, lodges
North American Porcupine	<i>Erethizon dorsatum</i>	Sighting
Bobcat	<i>Lynx rufus</i>	Tracks
Coyote	<i>Canis latrans</i>	Scat, tracks
Black Bear	<i>Ursus americanus</i>	Sighting, scat
Short-tailed Weasel	<i>Mustela erminea</i>	Sighting
Snowshoe Hare	<i>Lepus americanus</i>	Sighting, scat
White-tailed Deer	<i>Odocoileus virginianus</i>	Tracks, scat
Moose	<i>Alces alces</i>	Tracks, scat
Gray Seal	<i>Halichoerus grypus</i>	Sighting (offshore)

In addition to the above-noted species observed on the Site, suitable habitat exists for other mammals such Raccoon (*Procyon lotor*), and Red Fox (*Vulpes vulpes*), and small mammal species including shrews, voles, and mice are assumed to be present.

The NSDNR Hunter and Trapper Harvest website (NSDNR 2014a) was consulted in order to obtain information on species presence and harvest numbers for furbearer species, as well as White-tailed Deer and Snowshoe Hare, in Guysborough County from 2012-2013 (Table 6.4-9).

**Table 6.4-7:
Hunter and Trapper Harvest in Guysborough County, 2012-2013**

Common Name	Scientific Name	Number Harvested
Common Muskrat	<i>Ondatra zibethicus</i>	136
Fisher	<i>Martes pennanti</i>	7
American Beaver	<i>Castor canadensis</i>	207
North American River Otter	<i>Lontra canadensis</i>	72
American Mink	<i>Neovison vison</i>	27
Short-tailed Weasel	<i>Mustela erminea</i>	64
Bobcat	<i>Lynx rufus</i>	41
Canada Lynx	<i>Lynx canadensis</i>	1
Red Fox	<i>Vulpes vulpes</i>	14
Raccoon	<i>Procyon lotor</i>	15
Striped Skunk	<i>Mephitis mephitis</i>	3
Red Squirrel	<i>Tamiasciurus hudsonicus</i>	39
Coyote	<i>Canis latrans</i>	65
Snowshoe Hare	<i>Lepus americanus</i>	7,209

Common Name	Scientific Name	Number Harvested
White-tailed Deer	<i>Odocoileus virginianus</i>	325

The range of Canada Lynx (NSES - Endangered) is largely restricted to Cape Breton Island (Nova Scotia Lynx Recovery Team (NSLRT) 2006), so their presence in the Project area is considered unlikely. Eastern Cougar (*Felis concolor*) (COSEWIC - Data Deficient) has been reported in NS, but with little substantial evidence corroborating its presence.

While the Project area is not located within the core habitat for mainland moose (NSES - Endangered) as identified in the species' recovery plan (NSDNR 2007a), moose sightings have been documented in and around the Project area (M. Pulsifer, pers. comm.) and moose scat and tracks were noted by AMEC in July 2014. In September, a targeted field survey was conducted on the site, with the purpose of confirming presence of moose on the site and developing an understanding of the numbers and sex of moose using the site during the fall season and which areas and habitats they may be using. It is intended to supplement this survey data with winter track surveys and spring pellet surveys, to be conducted in early 2015. Results of the moose survey are discussed in Section 6.7, and details are provided in **Appendix H**.

Bats may be present in the Project area, and in fact, bat sightings have been reported within five km of the site in 2013 and 2014 (Nova Scotia Bat Conservation (NSBC) 2014). The town of Canso, located 12 km to the east of the site, reportedly supports a large concentration of bats (NSBC 2014). Bats in Nova Scotia commonly over-winter in abandoned mine workings; however, a search of the Nova Scotia Abandoned Mine Openings database (NSDNR 2014b) revealed no openings within 20 km of the site, and there are no documented caves or mines used by bats within 75 km (Moseley 2007). There are seven species of bats known to occur in Nova Scotia, four of which are migratory: Eastern Red Bat (*Lasurus borealis*), Hoary Bat (*L. cinereus*), Big Brown Bat (*Eptesicus fuscus*), and Silver-haired Bat (*Lasionycteris noctivagans*). The three year-round resident species, the Little Brown Myotis (*Myotis lucifugus*), Northern Long-eared Myotis (*M. septentrionalis*) and Tri-coloured Bat (*Perimyotis subflavus*), are listed as Endangered by SARA, COSEWIC and NSES, primarily due to the effects of the devastating fungal disease, White-nose Syndrome. Of these species, only the Little Brown Myotis and Northern Long-eared Myotis are likely to be present in the Project area; the four migratory species are irregular visitors to NS, and the Tri-coloured Bat is generally restricted to the southwestern part of the province (Broders *et al.* 2003).

Herpetiles

During terrestrial wildlife and freshwater field surveys conducted on the Project site in 2010 and 2014, reptile and amphibian observations were recorded during surveys for other taxonomic groups. Any evidence of herpetile species, including sightings, vocalizations, cast skins (snakes), skeletal remains, egg masses or presence of larvae, was recorded. Ponds and watercourses and their banks were scanned using binoculars during the day to detect presence of turtles, either in the water or basking, night-time field work included listening for vocalizations of frogs and toads, and coarse woody debris such as fallen logs and branches was overturned to look for salamanders and newts.

A list of herpetile species determined to be utilizing habitats on the proposed Project site is provided in Table 6.4-10.

**Table 6.4-8:
Reptile and Amphibian Species Identified in Project Area**

Common Name	Scientific Name	Evidence
Maritime Garter Snake	<i>Thamnophis sirtalis</i>	Sighting
Yellow Spotted Salamander	<i>Ambystoma maculatum</i>	Sighting of larvae
American Toad	<i>Bufo americanus americanus</i>	Sighting of adults, vocalizations
Spring Peeper	<i>Pseudacris crucifer crucifer</i>	Sighting of adults, vocalizations
Green Frog	<i>Rana clamitans melanota</i>	Sighting of adults, vocalizations
Northern Leopard Frog	<i>Rana pipiens</i>	Sighting
Bullfrog	<i>Rana catesbeiana</i>	Sighting of adults and larvae

Other herpetile species could be present based on habitat and range, including Eastern Smooth Green Snake (*Opheodrys vernalis*), Red-bellied Snake (*Storeria occipitomaculata*), Ring-necked Snake (*Diadophis punctatus*), Snapping Turtle (*Chelydra serpentina*), Painted Turtle (*Chrysemys picta*), Wood Turtle (*Glyptemys insculpta*), Wood Frog (*Lithobates sylvaticus*), Mink Frog (*L. septentrionalis*), Leopard Frog (*L. pipiens*), Blue-spotted Salamander (*Ambystoma laterale*), Spotted Salamander (*A. maculatum*), Eastern Red-backed Salamander (*Plethodon cinereus*), Four-toed Salamander (*Hemidactylium scutatum*), and Eastern Newt (*Notophthalmus viridescens*) (Gilhen 1984).

Snapping turtles (SARA: Special Concern; NSESA: Vulnerable) are not considered likely on the site based on the quality of available freshwater habitat. Wood Turtle (SARA and NSESA: Threatened), the most terrestrial of the three turtle species in NS, is considered to be possibly present although has not been observed in any surveys to date.

Invertebrates

Odonates (dragonflies and damselflies) were surveyed on the site in June and July 2010 by local odonate expert Mr. Paul Brunelle, assisted by AMEC staff. Additional specimens were collected during August and September 2010 by AMEC staff, and added to Brunelle's report. The complete odonate report, including details on the approach and methodology, is provided in **Appendix E**, Attachment B2. Odonates require wet areas for breeding, and the ponds, wetlands and watercourses in the Project area provide suitable habitat for these species. During the June and July surveys, the greatest odonate abundance was observed at Wetland 12 and at Wetland 2, Ponds 1 and 2; abundance was observed to be lower than expected at some other parts of the Project area (Fogherty Lake and Wetlands 17 and 19), although that may have been due in part to poor weather conditions at the time these location were surveyed. In all, 47 records of 25 species were documented during the June and July surveys (22% of the species known to occur in mainland NS), and an additional 18 records of 8 species (including 3 species not found in the earlier surveys) were collected in the August and September surveys (**Appendix E**). This was considered by Mr. Brunelle to be a moderate diversity. One species, the Spot-winged Glider (*Pantala hymenaea*) has a General Status rank of Sensitive.

Butterflies are expected to be present at the Project site, particularly in the central part, the wetlands and the coast, where suitable herbaceous vegetation exists. Butterfly observations were conducted by an experienced Maritimes Butterfly Atlas participant during the 2010 field

surveys; however, just one species, the Red Admiral (*Vanessa atalanta*), was identified in the Project footprint. According to the Maritimes Butterfly Atlas, there have been no observations to date in the 10 km by 10 km atlas square (20PR42) in which the Project area is situated (ACCDC: Maritimes Butterfly Atlas 2014). However, there have been a total of 10 records of 6 species in the two squares adjacent to 20PR42 for which observations were reported (20PR52 and 20PR41), all of which have a Canadian General Status rank of Secure in NS:

- Least Skipper (*Ancyloxypha numitor*);
- Peck's Skipper (*Polites peckius*);
- Tawny-edged Skipper (*Polites themistocles*);
- Long Dash Skipper (*Polites mystic*);
- Clouded Sulphur (*Colias philodice*); and
- Northern Blue (*Plebejus idas*).

6.5 Freshwater Environment

6.5.1 Methodology

This section summarizes the different freshwater environments located in the Project Area, including fish habitat. This information was gathered through desktop analysis, consultation with resource agencies, and on-site investigations in 2010 and 2014. **Appendix I** contains supporting field documentation for this subject. Freshwater fish and fish habitat baseline conditions were classified as lakes and watercourses based on size, depth, and percent of in-water vegetation.

The boundaries for aquatic assessment were based on the potential influence from the Project footprint, and the availability and accuracy of existing data. Efforts were made to sample all representative habitat types at each waterbody and watercourse location.

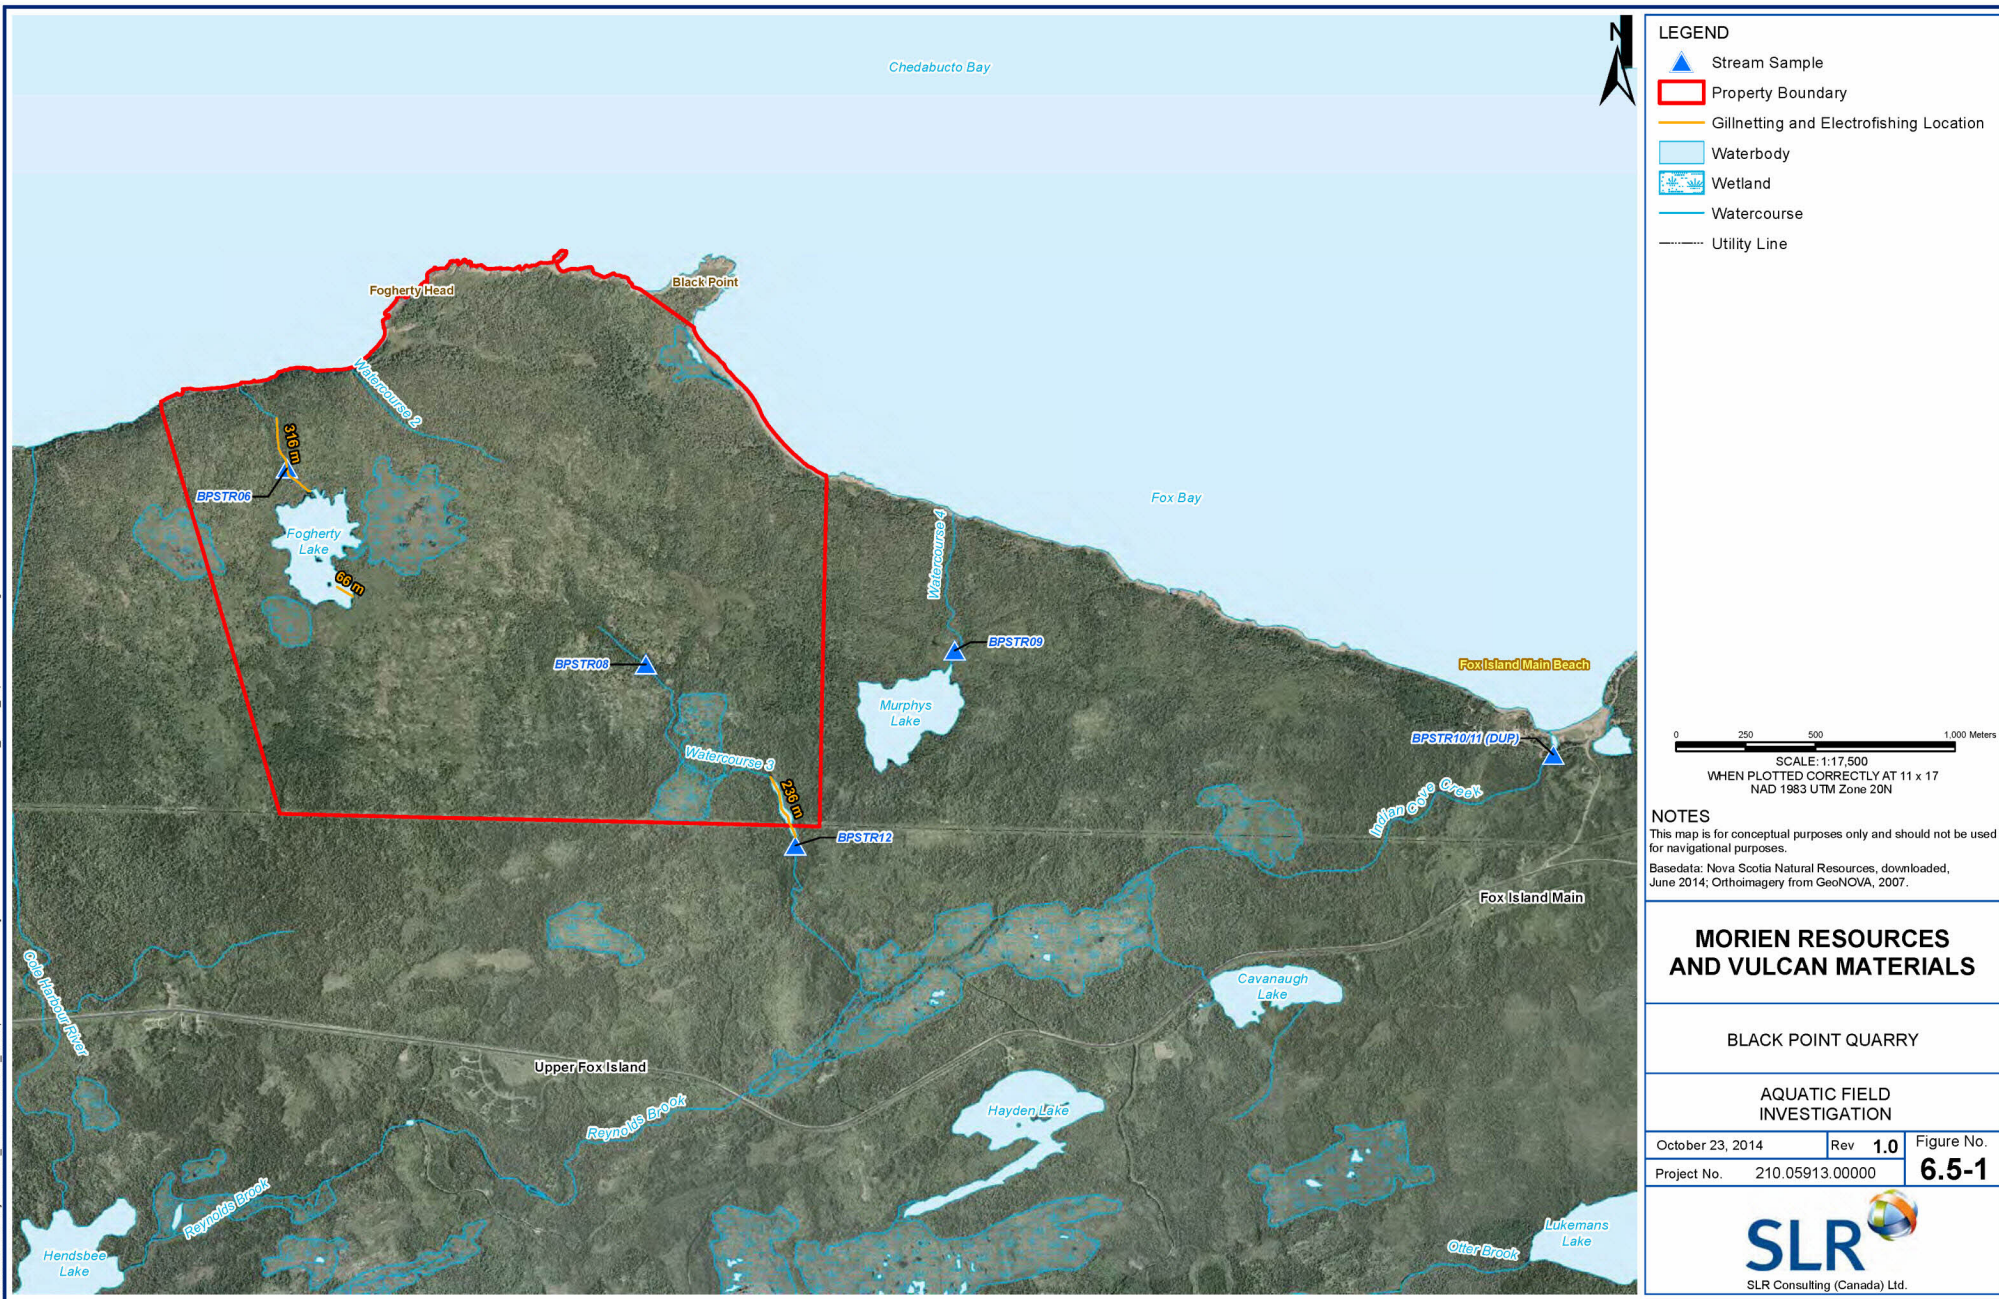

Ultimately this information was used to identify fish and fish habitat that are part of or support recreational, commercial, or Mi'kmaq fisheries.

6.5.1.1 Field Investigations

Aquatic field investigations were completed August 24th to 26th and September 20th to 22nd, 2010 by AMEC (**Appendix E**). Additional field data were collected on July 24th, 25th and 31st, 2014 by SLR. One water body and four unnamed watercourses were identified within the Project Area (**Figure 6.5-1**). The timing of the sampling events is summarized in the Table 6.5-1. Field investigations were completed in accordance with NBDNR/DFO New Brunswick Stream Survey and Habitat Assessment Protocol (Hooper *et al.* 1995).

Field investigations included fish community sampling, water quality samples and fish habitat mapping. The sampling program was designed to determine the presence or absence of fish within the Project Area. Fish collection methods were chosen to provide representative data for a broad range of species and size classes. Selection of sampling gear was based on waterbody size, depth and flow.

Prior to commencing fish community investigations, a Scientific Fish Collection Permit was obtained (License No. 323774) in accordance with Section 52 under the *Fisheries Act*.

6.5.1.2 *Habitat Assessment*

Habitat assessments characterized water body type, stream morphology, water chemistry, bank habitat, in-water habitat, and noted migratory obstructions and potential enhancement opportunities. Each distinct habitat type within the identified watercourses and water bodies were sampled. Observations were recorded on habitat assessment forms to limit variability of observations among field staff and to assure consistent observations throughout the Project Area. Representative photographs of water bodies were taken and catalogued.

Measured field parameters included conductivity ($\mu\text{S}/\text{cm}$), water depth (m), pH, water and air temperatures ($^{\circ}\text{C}$) and dissolved oxygen (mg/L).

Substrate classification was based on particle diameter and grouped into six substrate categories: Boulder (>461 mm); Rock (180-460 mm); Rubble (54-179 mm); Gravel (2.6-53 mm); Sand (0.06-2.5 mm); and Fines (0.5^{-3} -0.05 mm).

Vegetation was visually assessed by estimating percent cover. Dominant aquatic plants were identified and percent cover was estimated for each species present. Riparian vegetation was also assessed for density and species.

6.5.1.3 *Fish Collection*

Fish community data were collected using gillnets, baited minnow traps, and a backpack electrofisher: gillnets in deep water environments; minnow traps in shallow near shore areas; and backpack electrofishing in shallow stream environments.

Two of the four watercourses were fished using a five minute “spot sampling” electrofishing technique. In the south end of Fogherty Lake, two multi-panel gillnets (2.5 cm to 10 cm mesh size) were deployed for two hours, and four minnow traps (baited with cat food) were set for four hours.

6.5.1.4 *Water Quality*

Surface water samples from designated locations (**Figure 6.5-1**, Table 6.5-1) were collected in laboratory bottles, placed on ice and sent for analysis to AGAT Laboratories in Dartmouth, NS. Water samples analyzed for general chemistry, total metals (including mercury), total suspended solids, and low-level phosphorus.

**Table 6.5-1:
Summary of Field Investigations, 2010 and 2014**

	Fogherty Lake			Watercourse 1			Watercourse 2			Watercourse 3			Watercourse 4		
	Aug 2010	Sep 2010	Jul 2014	Aug 2010	Sep 2010	Jul 2014	Aug 2010	Sep 2010	Jul 2014	Aug 2010	Sep 2010	Jul 2014	Aug 2010	Sep 2010	Jul 2014
Habitat Survey	X			X			X			X					
Backpack electrofishing	X			X			X			X					
Minnow Traps	X			X			X			X					
Gill Nets	X			X			X			X					
Water Quality	X	X	X	X	X	X	X	X	X	X	X	X		X	X

Surface water quality data were compared to the most recent version of Canadian Council of the Ministers of the Environment (CCME) Canadian Water Quality Guidelines (CWQGs) for the protection of aquatic life (CCME 2012).

The CWQGs are numerical limits or narrative statements based on the most current, scientifically defensible toxicological data available for the parameter of interest, and are meant to protect all forms of aquatic life and all aspects of the aquatic life cycles, including the most sensitive life stage of the most sensitive species over the long term. Ambient water quality guidelines developed for the protection of aquatic life provide the science-based benchmark for a nationally consistent level of protection for aquatic life in Canada (CCME 2012). Water Quality Guidelines are provided in Table 6.5-2.

**Table 6.5-2:
Surface Water Quality Guidelines**

Parameter	Units	CWQG
Aluminium	ug/L	5
Ammonia (total)	mg/L	0
Antimony	ug/L	NV
Arsenic	ug/L	5

Note: CWQGs = Canadian Water Quality Guidelines (CCME 2012); NV = no value (no established guideline value)

6.5.2 Waterbodies and Watercourses

This section summarizes the key aquatic features within the Project Area. All of the data collected in the desktop analysis and field investigations are used to provide a description of the fish and fish habitat associated within the freshwater systems. The Project site includes one waterbody (Fogherty Lake) and three watercourses. A fourth watercourse (the outlet to Murphys Lake), is located immediately east of the Property boundary. These features were identified using topographic mapping and aerial photography followed by confirmatory field investigations.

6.5.2.1 Fogherty Lake

Fogherty Lake is situated approximately 420 m from Chedabucto Bay, where its flow ultimately outlets. This 6.8 ha lake is shallow and surrounded by trees, barrens and exposed rock. The lake is acidic (pH 3) and tea colored. Substrate within the lake comprises coarse materials such as bedrock and boulder, with an overlaying thin organic layer.

Vegetation surrounding the lake includes leather leaf (*Chaemodaphne calyculata*), sheep laurel (*Kalmia angustifolia*), possum-haw viburnum (*Viburnum nudum*), rhodora (*Rhododendron canadense*), chokeberry (*Photina* sp.) Labrador tea (*Ledum groenlandicum*), bunchberry (*Cornus canadensis*), black spruce (*Picea mariana*) and tamarack (*Larix laricina*). Yellow water lily (*Nuphar lutea*) was observed growing in the lake.

6.5.2.2 Watercourses

Watercourse 1 is the outflow of Fogherty Lake located to the north of the lake and the watercourse outlets into Chedabucto Bay. This watercourse has a well-defined channel with deep water and its substrate is dominated by fine grained materials. A beaver dam is located near the upstream extent of the watercourse. Upstream of the dam, the channel is deep and wide and the substrate largely consists of fines; downstream, the channel is a relatively narrow and shallow with one area of no visible flow. The northernmost 150 m of this watercourse were not surveyed in detail, as the watercourse flows down a steep drop off into Chedabucto Bay; however, the dimensions and substrate of the downstream reaches appeared similar to the observed run portions of the channel (AMEC 2011, **Appendix E**).

Watercourse 2 originates in a gully located within the north central portion of the Project site, and flows in a northwesterly direction to discharge into Chedabucto Bay. There was a great deal of deadfall in the channel valley when it was first surveyed in 2011. The upstream reaches were dry at the time of the survey, and further downstream the stream was very shallow; this watercourse is probably intermittent. No flow was observed in 2014. The last 220 m of this watercourse was inaccessible, as it flows down a steep slope to the ocean, as does Watercourse 1. However, the dimensions and substrate of the downstream reaches appeared similar to the rest of the channel (AMEC 2011, **Appendix E**).

Watercourse 3 originates in the southeast portion of the Project site, flows south through softwood forest, riparian shrub, and bog habitat (Wetland 1), and ultimately discharges into Reynolds Brooks and then Hendsbee Lake, south of the Project site. The downstream portion of the assessed section comprises a large pool resulting from a beaver dam on the watercourse just south of the property line.

Watercourse 4 is the outlet of Murphys Lake, located outside (east of) the Property boundary. The pH values measured at this location were on the order of 2.65. Due to the pH, fish habitat was not assessed in Watercourse 4.

Indian Cove Creek, which discharges into Indian Cove at Fox Island Main, was also sampled in 2014 to provide water quality data for comparison to the Project site (Section 6.2). This creek is also referred to as Fox Island Main Creek.

6.5.3 Fish and Fish Habitat

No fish were captured in Fogherty Lake or any of the watercourses during fish collection events. The field measured pH level in Fogherty Lake was 2.9 and in the watercourses pH levels ranged from 2.9 to 3.4. Based on the highly acidic conditions in freshwater environments, these water bodies are not likely to support fish species. Partial or complete barriers to Chedabucto Bay exist at outflow locations of all watercourses.

Inland freshwater fish species common to Guysborough and Canso include Speckled, Brown, and Rainbow Trout, Yellow and White Perch, Brown Bullhead, Shad, Gaspereau, Smelt, American Eel, Shiners, Sticklebacks, White Sucker, and Creek Chub. Creek Chub and Stickleback have been observed in systems with pH levels as low as 5.4 and 3.7, respectively (USGS 1982). Sensitivity of other freshwater fish to pH is as follows (Robertson & Bryan 2004):

- pH range tolerated by Trout, including Speckled Trout: 4.1 to 9.5
- Toxic limits for Perch: <4.6 to >9.5
- Toxic limits for Sticklebacks: ≤ 5
- Fish avoidance beyond range 5.4 to 11.4

In summary, most freshwater fish populations begin to disappear as pH approaches 5 and at pH of 4.5 most freshwaters are devoid of fish. Given the observed pH in study area waters, and the sensitivity of freshwater fish to pH, fish are not likely to persist in the study area. It should be noted that fish habitat was not assessed in Reynolds Brook, located 1.0 south of the Black Point site. For the purposes of the EIS, Reynolds Brook is assumed to support fish at some point between the wetland to the east that forms its headwaters and downstream Hendsbee Lake located approximately 3.0 km to the west.

A complete summary of freshwater habitat located within the study area is detailed in Table 6.5-3.

**Table 6.5-3:
Existing Fish and Fish Habitat Summary**

Waterbody	Flow	Thermal Regime	Substrate Type	Vegetation	Supports Fishery
Fogherty Lake	Permanent	Warmwater	bedrock and boulder thin organic layer	Moderate density and diversity	No
Watercourse 1	Permanent	Warmwater	fine substrate materials	Moderate density and diversity	No
Watercourse 2	Ephemeral	Warmwater	fine substrate	Moderate density and	No

			materials	diversity	
Watercourse 3	Permanent	Permanent	fine substrate materials	Moderate density and diversity	No
Watercourse 4	Permanent	Permanent	NC*	NC	No

NC* = not characterised; lack of fishery conclusion based on low pH measurements in 2014.

6.5.4 Water Quality

6.5.4.1 Field Parameters

In Fogherty Lake, surface water temperature was measured at 22.7°C in August 2010. The lake had acidic pH levels of 2.94. Conductivity was very low, 43 µS/cm. The water was well oxygenated, with surface dissolved oxygen (DO) content of 8.67 mg/L in August, 2010.

Surface temperatures in the watercourses ranged from 21.4°C to 14.9°C, pH ranged from 3.41 to 2.94, conductivity ranged from 91.0 to 43.0 µS/cm, and DO ranged from 4.52 to 8.47 mg/L in August and September 2010 respectively (Table 6.5-4). These parameters are indicative of acidic conditions with low conductivity and DO levels.

**Table 6.5-4:
Summary of Field Parameters, August 2010 Sampling Event**

Parameters	Fogherty Lake	Watercourse 1	Watercourse 2	Watercourse 3
Conductivity (µS/cm)	43	62	91	53
Water Temperature	22.7	21.4	14.9	16
pH (CCME Guideline 6.5-9)	2.9	3.4	3.2	2.9
Dissolved Oxygen (mg/L)	8.7	6.7	8.5	4.5

6.5.4.2 Conventional Parameters

In Fogherty Lake, laboratory measured pH was 4.3, indicating acidic conditions. Conductivity was measured at 52 µS/cm, and calculated TDS was 19 mg/L. The lake is relatively soft (hardness 3.2 mg/L), with an average surface conductivity of 52 µS/cm. Average turbidity values were low (mg/L and 0.7 NTU) indicating clear waters.

The laboratory pH results for water samples from the watercourses ranged from 3.9 to 4.3 indicating acidic conditions. Conductivity ranged from 59 to 102 µS/cm, and calculated TDS ranged from 22 to 33 mg/L. The watercourses are soft (hardness 3.5 to 5.8 mg/L), and turbidity values are low (0.7 to 2.8 NTU) indicating clear waters.

6.5.4.3 Nutrients

Total ammonia exceeded CWQGs in Fogherty Lake (0.03 mg/L) and all four watercourses, 0.09 mg/L in watercourse 1, <0.05 mg/L in Watercourse 2 and 3, and 0.08 mg/L in Watercourse 4.

Total phosphorus was 0.035 mg/L in Fogherty Lake and ranged from 0.03 mg/L to 0.16 mg/L in the watercourses. Nitrite and nitrate were below CWQG during sampling events in Fogherty Lake and the watercourses.

6.5.4.4 *Metals*

In Fogherty Lake, several metals exceeded their guideline values and this is likely related to the acidity of the water, which promotes mineral dissolution and metal mobility. Total aluminium and cadmium were above CWQGs at 335 ug/L and 0.023 ug/L, respectively. Iron (319 ug/L), lead (2.6 ug/L), manganese (16 ug/L), and zinc (26 ug/L) all exceeded their guideline values.

Aluminium and iron exceeded guidelines in all watercourses. Cadmium and lead concentrations also exceeded guidelines at 0.019 ug/L and 1.2 ug/L, respectively in Watercourse 3.

6.6 Marine Environment

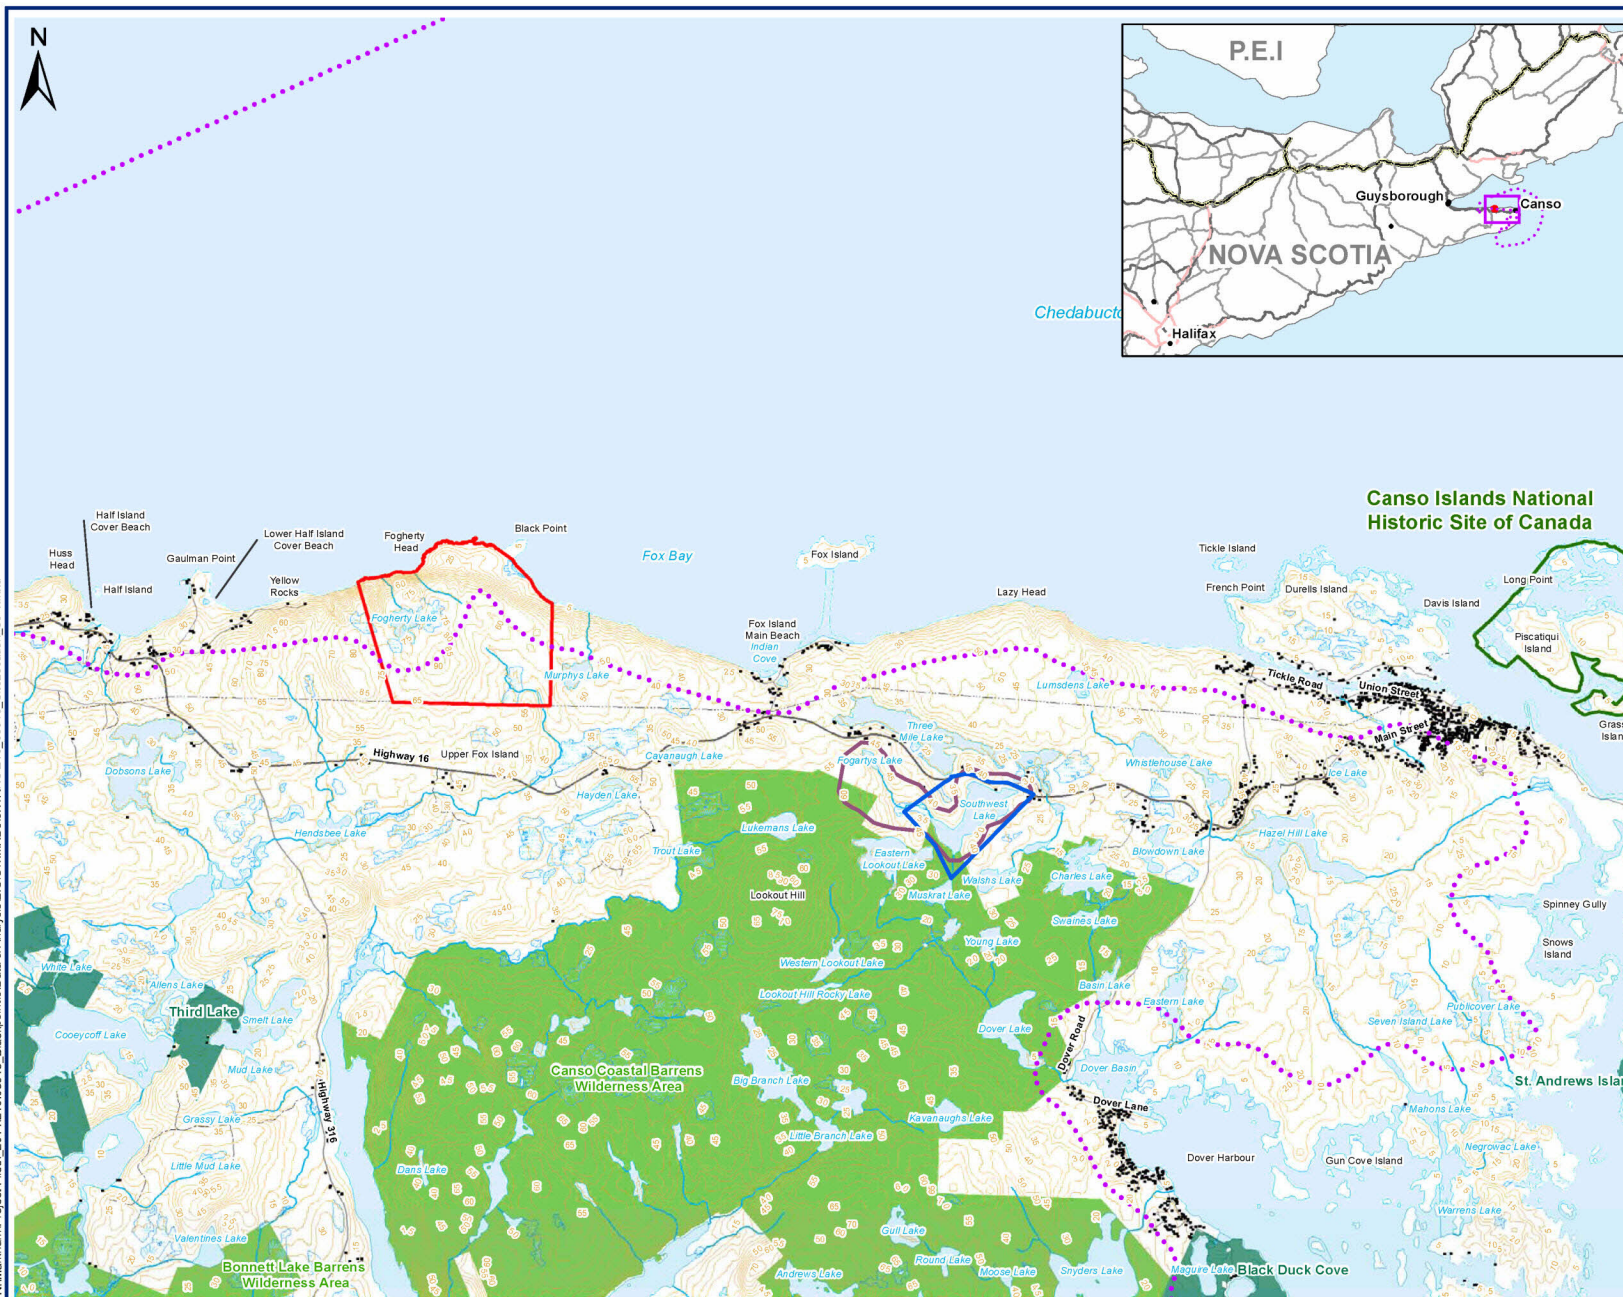

6.6.1 *Physical Oceanography*

6.6.1.1 *Overview*

Chedabucto Bay is approximately 45 km long from Canso to Guysborough (east to west) and approximately 20 km wide at its widest from West Arichat to Fox Island Main (north to south). The south shore of Chedabucto Bay between Canso and Guysborough is a relatively straight, steep coast with a narrow offshore shelf (CHS Chart 4335; Owens 1971). This is a shoreline resistant to wave erosion composed largely of rock platforms and low cliffs with pocket beaches of shingle and coarse sand. The amount of sediment in the littoral zone increases from east to west as indicated by the presence of spits and bars in the Salmon River - Guysborough area (Owens 1971).

This Project site is located within the Canso Ledges Ecologically and Biologically Significant Area (EBSA - **Figure 6.6-1**). This area extends from the mainland adjacent to White Head Island to Queensport along the coast of Chedabucto Bay and wraps around the Canso Peninsula. The Ledges extend approximately 10 km seaward in most areas (Hastings *et al.* 2014).

MORIEN RESOURCES AND VULCAN MATERIALS

BLACK POINT QUARRY

CANSO LEDGES EBSA

October 23, 2014	Rev 1.0	Figure No.
Project No.	210.05913.00000	6.6-1

SLR
SLR Consulting (Canada) Ltd.

The Canso Ledges EBSA is an area of high productivity for cod, wolffish, lobster, snow crab, and historically for cod spawning. A steep seabed close to shore results in relatively high diversity of species in a relatively narrow nearshore band (e.g., lobsters, snow crab, shrimp) that are normally more dispersed when depth gradients are shallower.

Extensive and diverse marine algae contribute to the primary productivity of the area. There are fewer eelgrass beds and salt marshes in this area compared to other parts of the Nova Scotia coast due to the rocky shores which better support kelp (algae) growth (Gromack *et al.* 2010).

In the past Fin Whales aggregated in the Canso Ledges area in winter but whether they still use the area is unknown. Dolphins likely congregate in the area in summer. Migrating waterfowl, particularly Common Eider, use the area for spring staging (late March-April). Colonies of Great Blue Heron, Common Eider and Double-crested Cormorant breed in the area (April to late August), and probably Common and Arctic Terns as well. Deep areas off the Canso Ledges referred to as the Deep Holes of Canso serve as a deep water reserve for lobster, supporting some of the largest lobsters along the Eastern Shore (Doherty and Horsman 2007). The ecologically significant features of Chedabucto Bay as described by Hastings *et al.* (2014) are summarized at the end of this section.

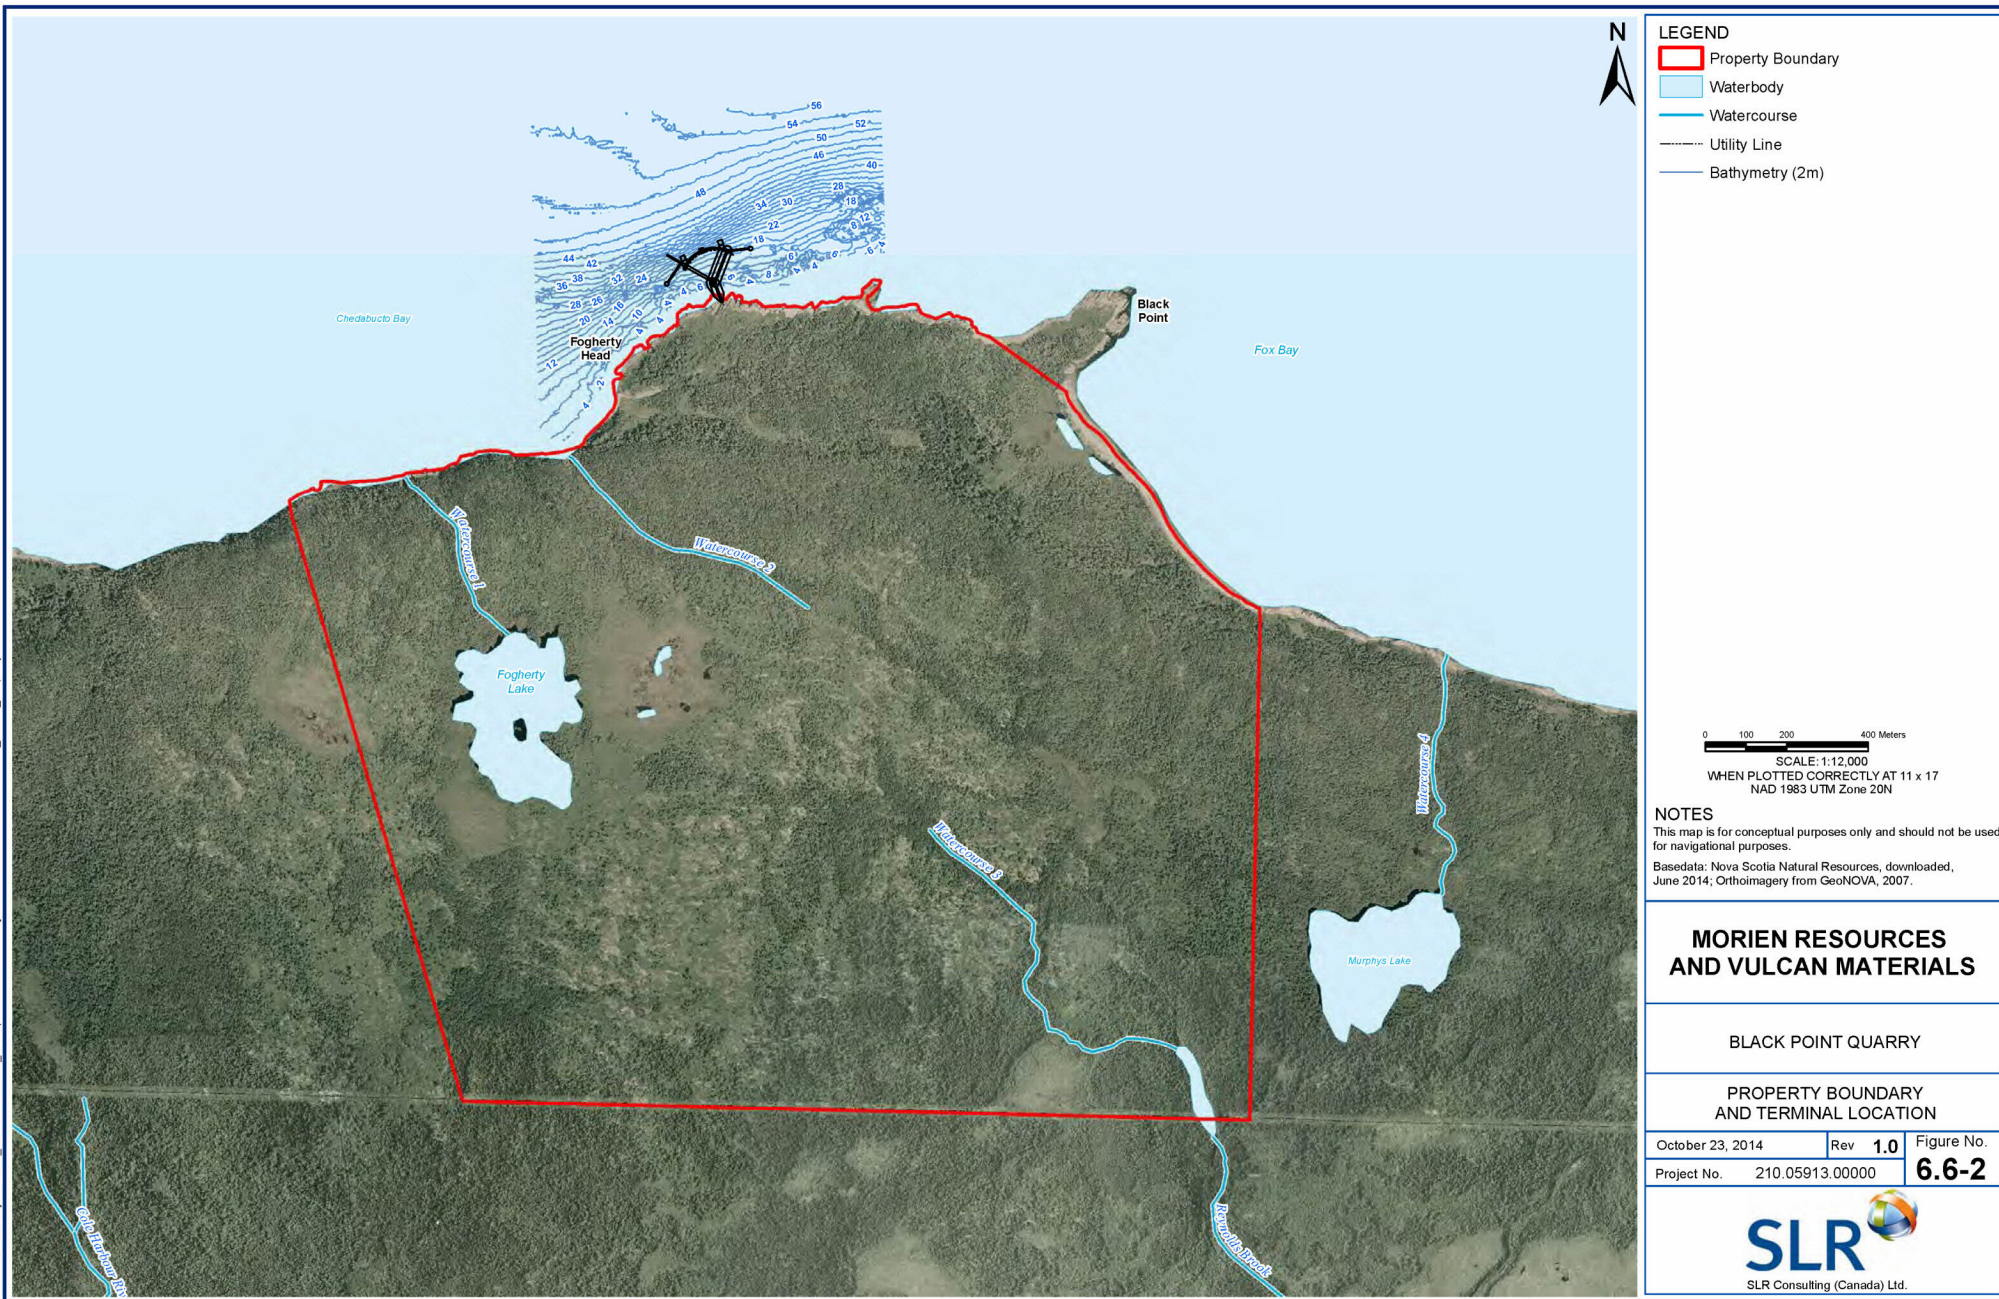

6.6.1.2 Bathymetry

Chedabucto Bay borders the Project site to the north. Chedabucto Bay is 107.9 m deep at the mouth near Canso and has a maximum depth of 146 m at the seaward extent of the Project Area (Canadian Hydrographic Service Charts 4013 and 4321). The area is tidally dominated with a high tidal to freshwater ratio of approximately 487:1 (Gromack *et al.* 2010). Chedabucto Bay has a flushing time of 295.3 hours (DFO 2008a) and has been classified as an intermediate pelagic bay (Greenlaw 2009). Chedabucto Bay has a watershed drainage area of 2,148.4 km² (DFO 2008a).

The seabed descends to a depth of 30 m within approximately 300 m from the shoreline where the marine terminal is proposed (Figure 6.6-2). Along the south shore of Chedabucto Bay, the coastline forms a relatively straight fault line-scarp with low, resistant rock cliffs and intertidal platforms. There is an extensive bed of *Ascophylum nodosum* (a common brown alga sometimes referred to as Rockweed) in the area.

Water depth ranges from 0 to approximately 15 m in the area proposed for the rubble mound structure and ranges from approximately 16 m to 22 m deep where the mooring and berthing structures will be located.

6.6.1.3 Hydrography

Currents

Dominant currents in the Study Area originate in St Lawrence River and the Gulf of St Lawrence (**Figure 6.6-3**). The Nova Scotia Current is the primary inflow, originating in the Gulf of St. Lawrence and entering the region through Cabot Strait. This current has a general south-westward drift over the Scotian Shelf, passing across the mouth of Chedabucto Bay and continuing into the Gulf of Maine (Herbert *et al.* 2012). Tidal currents in Chedabucto Bay off the Project Area are approximately 2.6 knots (0.51 m/s).

**Figure 6.6-3:
 Surface Currents on the East Coast**

Source: CCG 2012.

Tides

Chedabucto Bay experiences semi-diurnal tides with mean tidal ranges of 1.28 m (Canso) to 1.37 m (Guysborough). The highest tides are about 2.0 m at Canso and slightly less (1.95 m) at Guysborough (Owens 1971).

Wind and Waves

Wind data summarized from a meteorological station at Canso from 1964 to 1970 show that the highest wind speeds are mainly from the north-west (see also Figure 6.3-1) and occur from December to February (Owens 1971). Table 6.6-1 summarizes average and maximum winds recorded at Canso from 1964 to 1970⁴. Anemometer data collected at Canso (for a recording period of less than 10 years) indicates a maximum hourly wind speed from the northwest of about 97 kph and 80 kph from the east (CCG 1981); these values are higher than those reported in Table 6.6-1.

**Table 6.6-1:
Average and Maximum Winds (Canso 1964 – 1970)**

Month	Average of the Monthly Mean Speeds (kph)	Prevailing Direction	Average of the Monthly Maximum Recorded Speed (kph)	Direction Dominant

As noted in Section 6.3.2, wave heights at the MSC50 grid point near the Project (45.4N, 61.1W, approximately 5 km northeast of the site) were less than 2 metres in height 92.77% of the time whereas waves from 2 to 3 metres and 3 to 4 metres were present 5.96% and 1.02% of the time, respectively. Waves in excess of 4 metres were relatively minor and only present over 0.25% of the year on average. The annual wave rose is presented in **Figure 6.6-4** while wave direction and intensity is compiled in Table 6.3.6.

Figure 6.6-4:
Annual Wave Rose (45.4N, 61.1W)

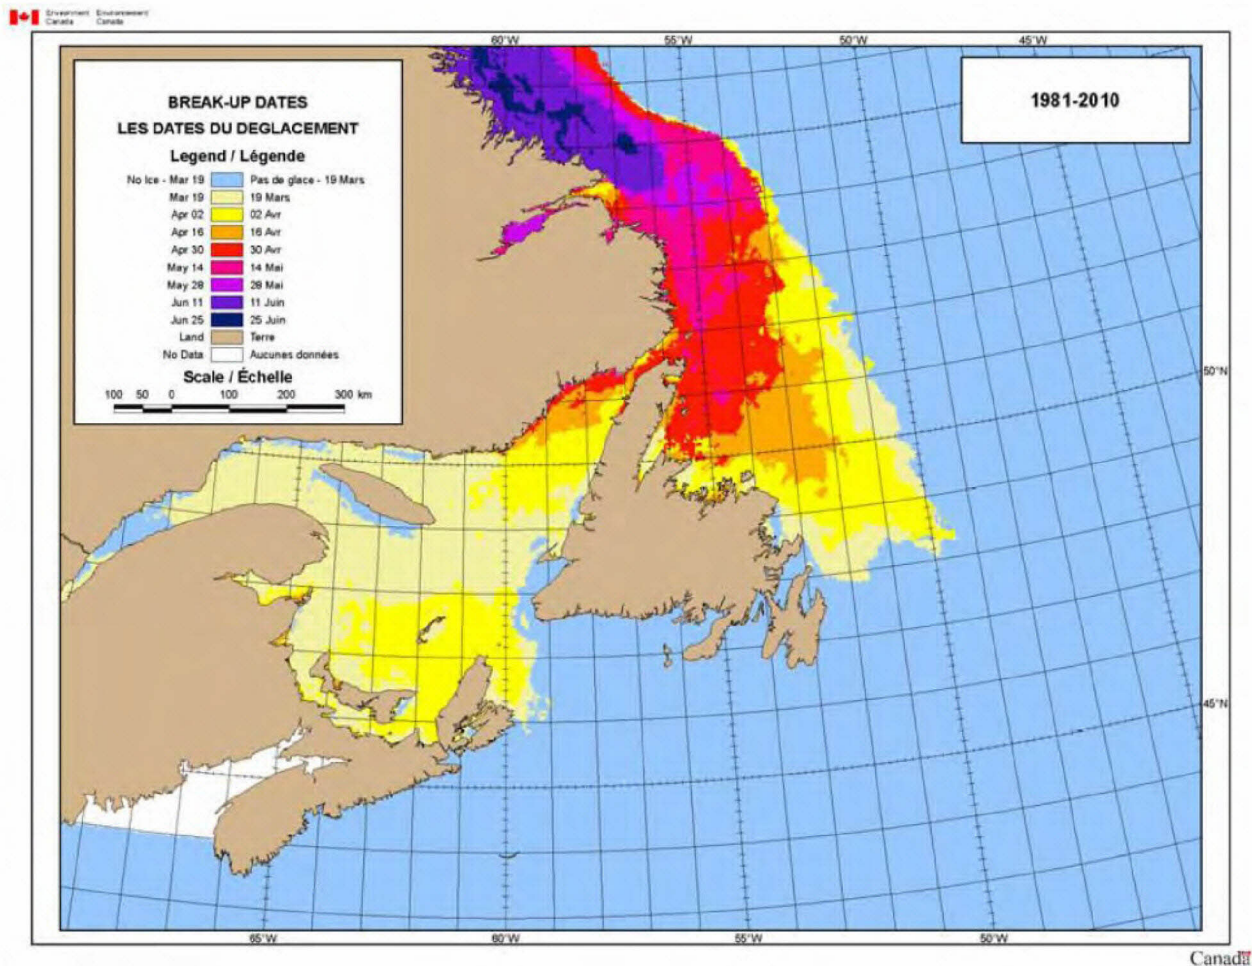

Source: MSC50 Environment Canada data in CBCL 2004

Chedabucto Bay has a broad opening the east and the bathymetry at the mouth of the Bay permits ocean waves to penetrate deep into the Bay. This suggests that the most severe conditions within Chedabucto Bay will be comparable to those for the Scotian Shelf area off Chedabucto Bay. Using 10 years of ship-observed wave data for the Scotian Shelf Neu (1980, reported in CCG 1981) found the largest significant wave height for a one-year period to be 8.6 m and for 10 years, 11.7 m. The significant wave height is taken to be the average of the highest one-third of all the wave heights present. The maximum wave height is much higher than the significant height; in the open ocean the ratio of maximum wave height to significant wave height ranges from about 1.8 to 2.0.

Storm surge is described in Section 8.0 Effect of the Environment on the Project.

Ice

Ice typically forms around Prince Edward Island, along the north shore of Nova Scotia and along the western shore of Cape Breton in January and persists until early April (CCG 2012). In these areas, ice ridging can be extensive but seldom exceeds 2 m in height. Typically the southern and eastern shores of Nova Scotia and Cape Breton, including Chedabucto Bay, remain ice free over the winter although ice may in fact form or move into the Bay on occasion (Figure 6.6-4; CCG 2012).

**Figure 6.6-5:
 Variability of Ice Extent on the East Coast**

Source: CCG 2012.

There has been essentially no ice on the Scotian Shelf from April 2009 until the end of the season in May 2012. The ice volume during 2012 was the fourth lowest in the 51 year record. Only 1969, 2010 and 2011 had lower coverage and volume. The periods 1987-1993 and 2003-2004 were predominantly colder than normal, and 1999-2000 and 2010-2012 were warmer than normal (Hebert *et al.* 2012). The ice coverage varies considerably from year to year but in general, there were normal to above normal conditions from 1980/81 to 1994/95 then below normal conditions from 1995/96 to 2009/10 (CCG 2012).

6.6.2 Marine Biology

6.6.2.1 Methodology

Available reports and maps, consultation with resource agencies, and on-site investigations form the basis of information for characterizing existing conditions for key fish and fish habitat features in the marine environment in the Project Area as defined in Section 5.0. **Appendix J**

presents supporting field notes and other documentation that helps to characterise the marine biological environment.

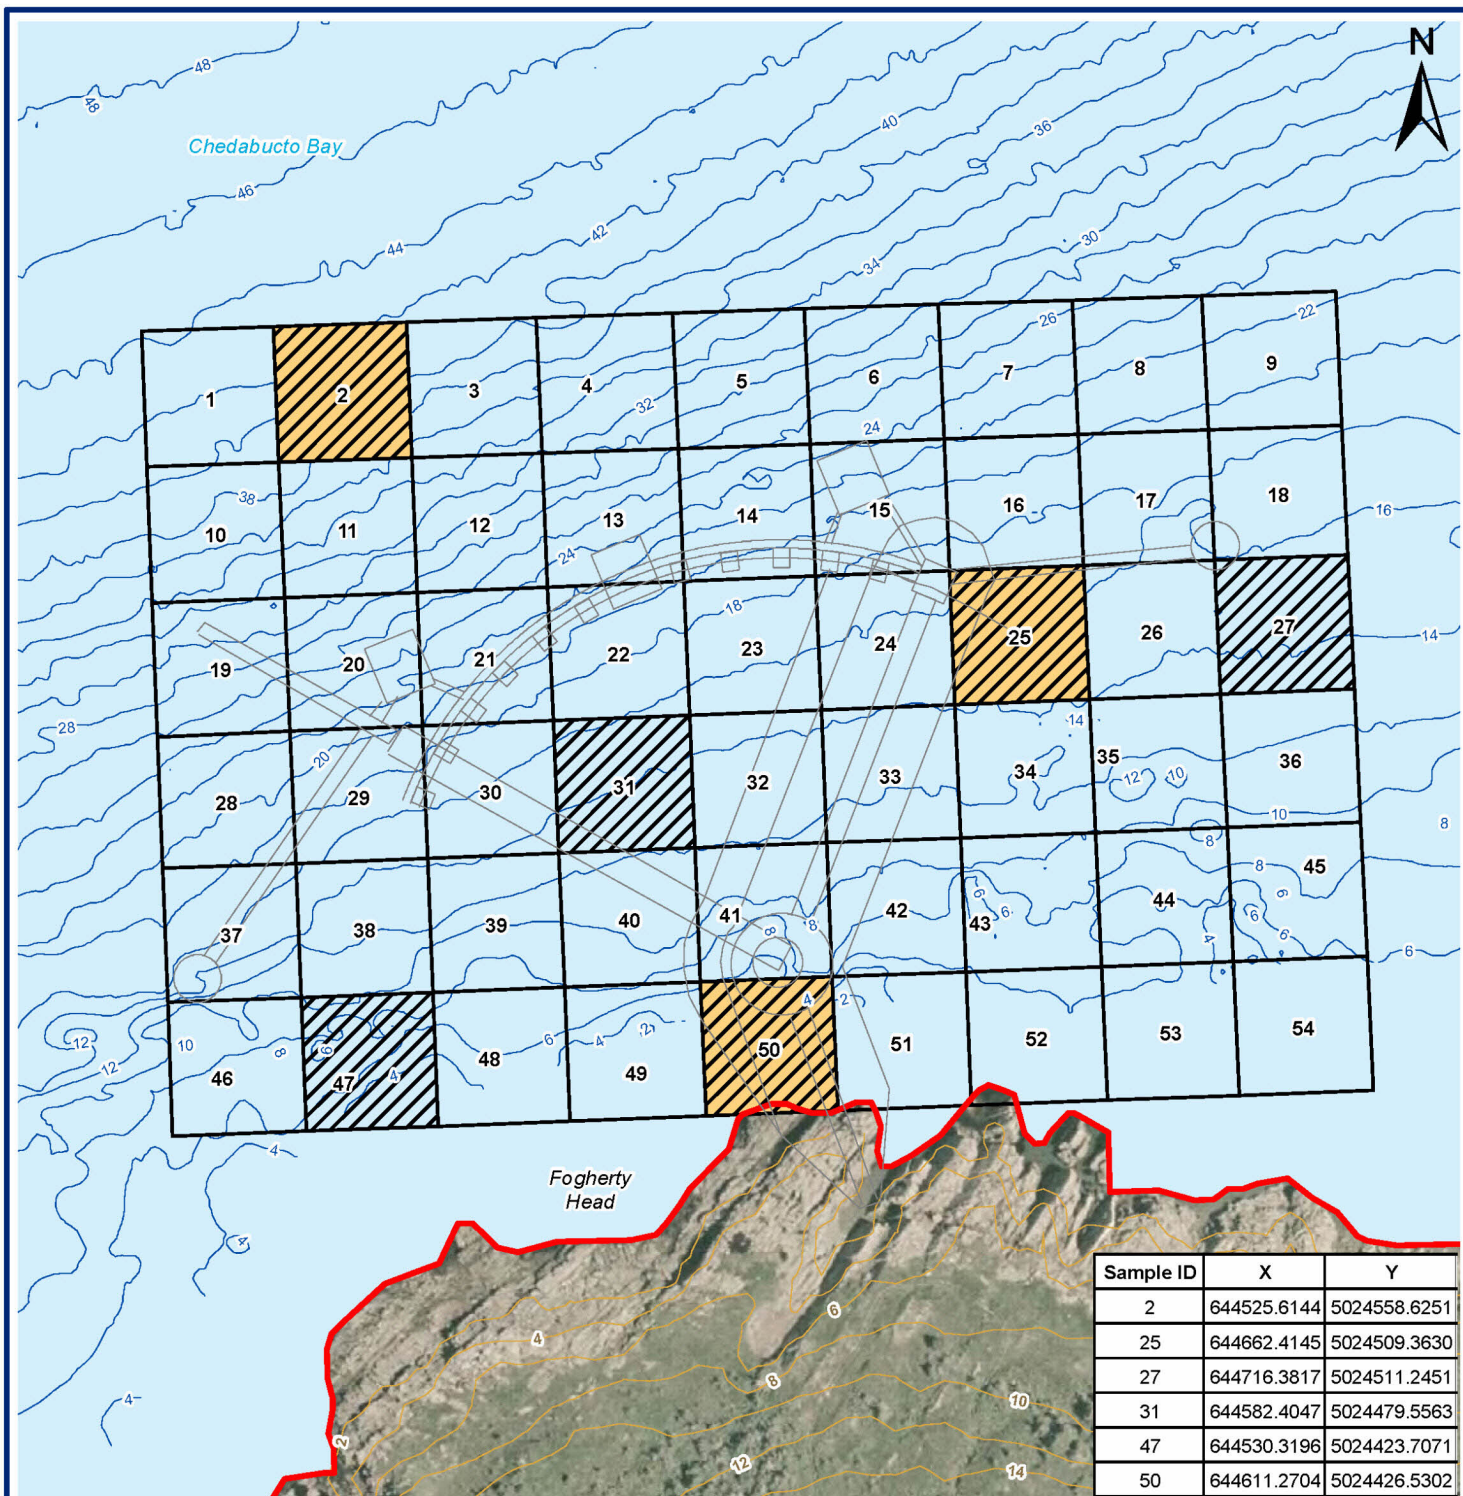

Information on fish and fish habitat collected for the marine environment will be used to:

- Characterize habitat type, function and fish presence;
- Form the knowledge base to assess project impacts;
- Inform and recommend mitigation strategies;
- Form the basis upon which to characterize residual effects; and
- Form the basis upon which to identify a suite of measures to offset serious harm to fish and fish habitat.

The Study Area has been defined by considering Project-environment interactions and includes the Project Area (i.e., the Property boundary including the seabed Crown lease), Adjacent Areas and Chedabucto Bay. The most detailed studies occurred within the Project Area. Efforts were made to characterize representative habitat types in the Adjacent Areas and Chedabucto Bay. Ultimately this information was used to identify fish and fish habitat that are part of or support recreational, commercial, or Mi'kmaq fisheries.

Field Investigations

The area of detailed aquatic investigation included the zone proposed for installation of the marine terminal. The zone extended 240 m along the shoreline and 165 m seaward, perpendicular to the shore, for a total area of 39,600 m². For comparison, the marine terminal rubble mound is expected to occupy about 11,000 m² of the seabed. This larger area was characterized by underwater video surveys. Video recordings of approximately 1200 meters of sea floor was compiled along 6 transects and reviewed to characterize the existing seabed. **Figure 6.6-6** presents the video transect locations. Transect 1 (T1), T2, and T3 each measured 250 m and were oriented parallel to the shoreline while T4, T5, and T6 each measured 150 m and extended perpendicular from the shoreline. Waypoints for the start and finish of each transect were measured and recorded using a handheld GPS. The underwater observations extend approximately 1 m on either side of the transect line.

6.6-6

Marine field investigations were completed between August 31 and September 3, 2010 within the proposed footprint of the marine infrastructure. The underwater surveys captured information relating to the presence and absence of benthic invertebrates, macrofaunal and macrofloral species. Substrate characteristics, algae cover, and incidental fish were also documented. Observations along the video transects were made for each 5 m segment.

The following observations were made for each 5 m increment along each transect:

- Visual estimate of substrate grain size distribution (in order of dominance);
- Identification and abundance of macrofaunal species; and
- Identification and percent coverage of macrofloral species.

In order to review the 5 m transects and assess species presence and abundance, four categories were developed as described by AMEC in **Appendix J** (Table 6.6-3).

**Table 6.6-4:
Field Investigation Methodology**

Category		Description
A	Abundant	Numerous (not quantitative) observations made throughout the entire 5 m segment.
C	Common	Numerous (not quantitative) observations made intermittently along the 5 m segment.
O	Occasional	Quantifiable observations made intermittently along the 5 m segment.
U	Uncommon	Quantifiable observations made infrequently along the 5 m segment.

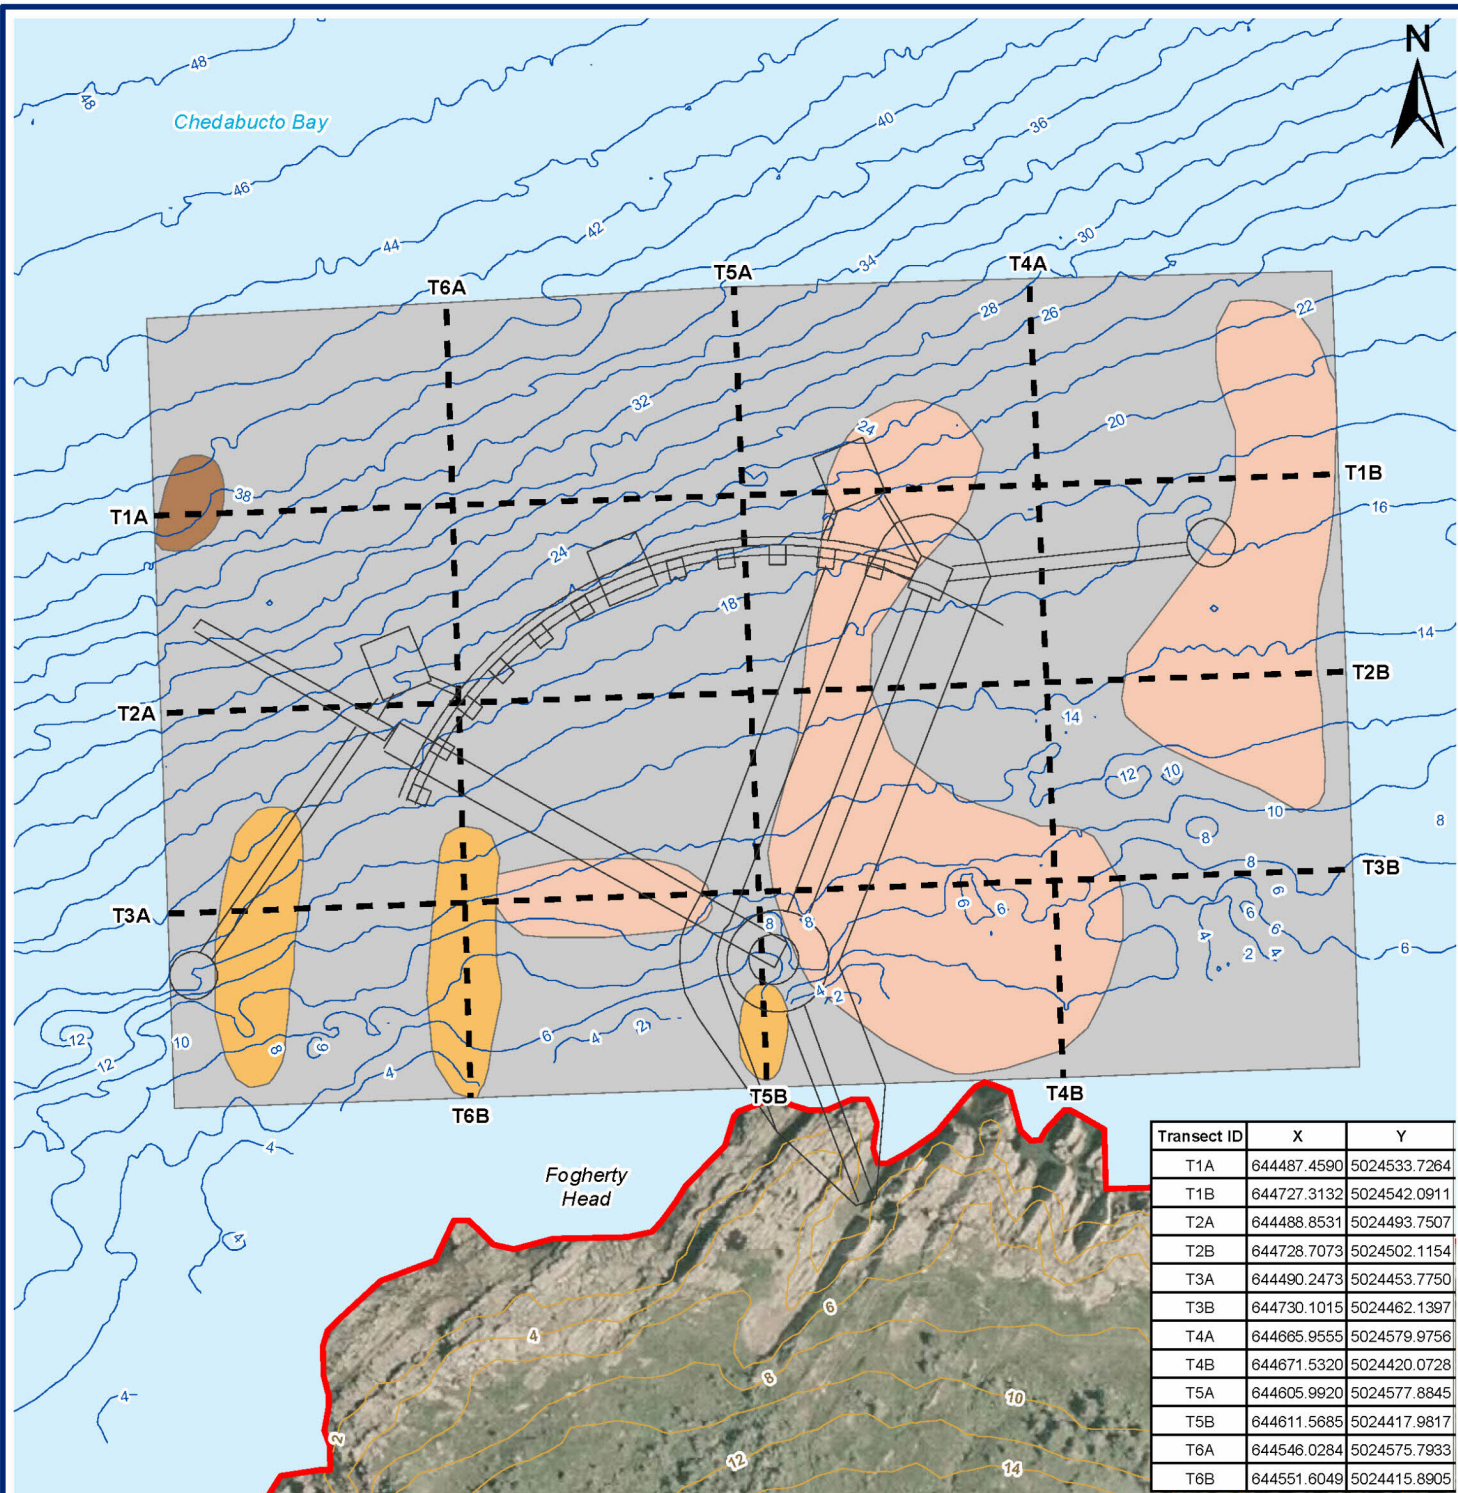

Marine Invertebrate Community Survey

Benthic invertebrates are animals that colonize on or near the sea bottom in aquatic environments. Benthic invertebrates are considered effective indicators of ecosystem conditions because

- a. they have limited mobility and are therefore constantly exposed to the effects of pollution;
- b. they are reasonably long-lived so the effects of environmental stressors can be quantified;
- c. short-term changes in environmental conditions do not dictate sampling results; and
- d. they are a well-documented, aquatic ecological indicator with various tolerance levels.

To facilitate the collection of benthic invertebrates, a sampling grid was plotted over a map of the marine terminal footprint, and sampling locations within the footprint were selected randomly using a random number generator (**Figure 6.6-7**). In total, six benthic invertebrate sampling stations were used to characterize existing conditions and inform assessment of effects.

Figure No.

Project No. 210.05913.00000

6.6-7

On September 1, 2010 Connors Diving Services performed the sample collection. The diver placed a 0.25 m² quadrat on the substrate surface and used a small container to penetrate the substrate, to a minimum depth of 5 cm. Several litres of sediment were collected at each of the six sampling locations. The sediment was placed in a clean 20 L bucket, brought to surface, and thoroughly mixed. Four litres of each sample was measured for the benthic invertebrate sample.

The samples were sieved through a 1.0 mm screen using filtered seawater to remove the risk of osmotic shock to any organisms. The samples were preserved with 70% isopropanol in 1 L glass Mason jars. Each jar was inverted several times to insure proper mixing and preservation.

Samples were analyzed by BioTech Inc. (Smithtown, NB) for benthic invertebrate identification and enumeration.

Statistical analysis of the benthic invertebrates' samples included:

- Benthic invertebrate identification and enumeration for each station;
- Number of species and number of individuals per species for each station;
- Number of species per station by major taxonomic group; and
- Density (number of organisms/m³) and biomass (g/m² wet weight) for each station.

Marine Sediment Sampling Program

The sediment sampling program and analysis was completed in accordance with Environment Canada's publication *Guidance Document on Collection and Preparation of Sediments for Physiochemical Characterization and Biological Testing* (December 1994).

In order to assess disposal options for sediment potentially removed during the construction of the Project, the analytical sample results were compared to the following:

- Canadian Environmental Protection Act (CEPA) Disposal at Sea Regulations (formerly the Ocean Dumping Control Act);
- Canadian Council of Ministers of the Environment (CCME) Probable Effects Levels (PELs) for marine/estuarine sediment;
- CCME Soil Quality Guidelines (SQGs) for the Protection of Environment and Human Health in agricultural, residential/parkland, and commercial/industrial applications; and
- Atlantic Risk-Based Corrective Action (RBCA) Tier 1 Version 2.0 Risk-Based Screening Levels (RBSLs).

The sediment samples were collected concurrently with the benthic invertebrate sampling program. On September 1, 2010, a total of six marine sediment samples were collected from the same well-mixed benthic invertebrate samples within the proposed footprint of the marine terminal.

Two 250 ml jars of sediment were collected at each station. A duplicate jar of sediment was collected for each of the stations to safeguard against loss or damage during transport. All samples were sent to Maxxam Analytics Inc. for chemical analysis. Maxxam is accredited with the Standards Council of Canada. Three of the six samples (GQ 02, GQ 25, and GQ 50; **Figure 6.6-7**) were analyzed for parameters listed in **Appendix J**.

6.6.2.2 Results

This section summarizes key aquatic features within the Project Area. All data collected in the desktop analysis and field investigations are used to provide a description of marine ecosystems.

Marine Environment

The marine environment is characterized using information from existing reports and supplemented by field investigations. As noted water depth in Chedabucto Bay is approximately 108 m at the mouth near Canso. Chedabucto Bay is classified as an intermediate pelagic bay with a drainage area of 2,148 km². The intertidal and adjacent sublittoral areas are subject to the effects of scouring by winter ice and shifting cobblestone material. Chedabucto Bay supports productive and diverse fisheries (Gromack *et al.* 2010).

Substrate type and vegetative cover are key components that contribute to the ecological structure of the marine environment. Substrate type and percentage of cover facilitate development and growth and thus influence the diversity and abundance of floral and faunal species. Within the area of potential Project impact, the marine substrate is dominated by coarse materials including cobble, rock, and large boulders (**Figure 6.6-7**). Small areas of finer grained substrates consisting primarily of sand were documented along certain transects.

Within the Project Area, algal cover was sparse (0-10%) in deeper waters and increased to 50-90% cover in the near shore areas. The algal canopy is dominated by the brown algal species black whip weed (*Chordaria flagelliformis*), bladderwrack (*Fucus sp.*), and sea colander (*Agarum clathratum*). Other species present in lesser densities included sugar kelp (*Laminaria saccharina*), tube weed (*Polysiphonia lanosa*), an encrusting red alga (*Leptophyllum sp.*), Irish moss (*Chondrus crispus*), a brown alga (*Pilayella littoralis*), a green alga (*Acrosiphonia arcta*), and a red alga (*Plumaria plumosa*). Of note, green fleece (*Codium fragile*), an invasive species in Nova Scotia (Invasive Species Alliance of Nova Scotia, 2011), was noted along T2. This species has been previously reported around the Canso area (Watanabe *et al.* 2010).

6.6.2.3 Benthic Habitat and Communities

The results of the six benthic samples reflect a benthic community dominated by annelid worms (polychaetes) and mollusks (gastropods). The most common identified polychaetes include the worm *Aricidea* (syn. *Acmira*) catherinae, sinistral spiral tubeworm (*Spirobis borealis*) and cirratulids (*Tharyx spp.*). The dominant bivalves included the common tortoiseshell limpet (*Tectura testudinalis*) and interrupted turbonille (*Turbonilla interrupta*). A complete list of identified species at the six sampled locations is included in **Appendix J**.

The benthic invertebrate assemblage was highest at Station 2 (GQ 25) and lowest at Station 4 (GQ 31): 318 and 109 individuals respectively. The benthic invertebrate assemblage at Station 1 (GQ 02) contained the greatest number of taxa and Station 4 contained the lowest number of taxa (GQ31); 47 and 17 taxa respectively. Station 2 is the deepest of the 6 Stations. Due to the presence of a diverse community assemblage collected at this site, dissolved oxygen content and food sources are likely not limiting factors.

6.6.2.4 Marine Sediment Quality

As noted above, results of sediment quality data collections were compared against the relevant CEPA, CCME, SQGs, RBCA sediment quality guidelines. Three of six collected sediment samples were analyzed. The results of the analysis are summarized in **Appendix J**. The complete set of analytical results, including laboratory Quality Assurance/Quality Control and Certificates of Analyses for all parameters tested are provided in **Appendix J**.

No exceedance was noted for any of the above mentioned guidelines for any parameters in the three samples. Two samples (GQ 25 and GQ 50) were predominantly gravel (76-82%) with lesser amounts of sand (16-19%), silt (1-3%), and clay (<1-1%). Sample GQ 02 was a mix of gravel (51%) and sand (42%) with lesser amounts of silt (5%) and clay (3%). Total carbon content in the three samples collected and analyzed ranged from 0.6 to 1.62 g/kg (AMEC 2011 in **Appendix J**).

6.6.2.5 Fish Community

Chedabucto Bay is a cool water marine environment which supports a diverse fish community. A number of fish species reside within the Bay, and additional species migrate from nearby water bodies such as the Strait of Canso and St Georges Bay to feed or spawn. The fish and fish habitat within Chedabucto Bay are valued for their ecological services as well as economic benefits. Fishing is regulated to fixed gear only in Chedabucto Bay (except for scallops) in order to preserve the high marine diversity and productivity. A number of species listed under SARA

and assessed by COSEWIC are found in the Bay (Gromack *et al.* 2010). Please see Section 6.7 for a description of marine Species at Risk.

Chedabucto bay supports shellfish, demersal fish, and pelagic fish populations (**Appendix J**). Demersal fish are those that occupy habitat near the sea bottom, while pelagic fish are associated with habitat within the water column and closer to the surface. The Bay supports more than 50 fish species, however only two fish species were noted along the transects during field investigations. Species present in the Project Area included Cunner (*Tautogolabrus adspersus*) and Shorthorn Sculpin (*Myoxocephalus scorpius*). Cunner and Sculpin are demersal fish and often congregate around wharves. Neither of these species are part of a recreational, commercial or Mi'kmaq fishery. Fox Island Beach, located several kilometers east of the Project area, was sampled in 2005 and 2006 for fish abundance and diversity of juvenile fish. This sampling resulted in the capture of Sand Lace, Hake species, and Grubby. These species are typically associated with sand substrates, which are more or less absent from the immediate Project Area location. For a complete list of species found in the Bay, please refer to **Appendix J**.

The hard bottom and algal cover present within the Project Area provides habitat for many invertebrate species (Table 6.6-4). The most common species noted from the video transects include deep sea scallop (*Placopecten magellanicus*), blue mussel (*Mytilus edulis*), green sea urchin (*Strongylocentrotus droebachiensis*), and American lobster (*Homarus americanus*). Other invertebrate species observed along the transects included American oyster (*Crassostrea virginica*), northern rock barnacle (*Semibalanus balanoides*), Bowerbank's halichondridia (*Halichondria bowerbanki*), frilled anemone (*Metridium senile*), periwinkle (*Littorina sp.*), sea cucumber (*Cucumaria frondosa*), sea peach (*Holacynthis pyriformis*), sea star (*Asterias sp.*), and waved whelk (*Buccinum undatum*). Due to the depths of the surveyed areas divers had to move at speed greater than optimal for characterization. The combination of the speed of the diver's movement and a cobble bottom resulted in difficulty discerning the presence of small invertebrates such as periwinkles.

Table 6.6-5:
Invertebrate Occurrence in Strait of Canso – Inhabitants Bay – Chedabucto Bay Area

Common Name	Scientific Name	Present During Field Investigations (AMEC 2011)
American Lobster	<i>Homarus americanus</i>	✓
Sea Scallop	<i>Placopecten magellanicus</i>	
Snow Crab	<i>Chionoecetes opilio</i>	
Rock Crab	<i>Cancer irroratus</i>	
Hermit Crab	<i>Pagurus bernhardus</i>	
Green Crab	<i>Carcinus maenas</i>	
Pink Shrimp	<i>Penaeus duorarum</i>	
Northern Shrimp	<i>Pandulus borealis</i>	
American Oyster	<i>Crassostrea virginica</i>	✓
Soft shell clams	<i>Mya arenaria</i>	
Bar clams	<i>Spisula solidissima</i>	
Blue mussel	<i>Mytilus edulis</i>	✓

Horse mussel	<i>Modiolus modiolus</i>	
Green Sea Urchin	<i>Strongylocentrotus droebachiensis</i>	
Northern Rock Barnacle	<i>Balanus balanoides</i>	
Bowerbank's Halichondria	<i>Halichondria bowerbanki</i>	✓
Friiled Anemone	<i>Metridium senile</i>	✓
Periwinkle	<i>Littorina sp.</i>	✓
Sea Cucumber	<i>Cucumaria frondosa</i>	✓
Sea Peach	<i>Holacynthia pyriformis</i>	✓
Sea Star	<i>Asterias sp.</i>	✓
Waved Whelk	<i>Buccinum undatum</i>	✓

6.6.2.6 Species at Risk

No freshwater fish Species at Risk were encountered within the Project area during field investigations. Marine Species at Risk including fish and marine mammals are described in full in Section 6.7.

6.6.3 Ecological Summary

Hastings *et al.* (2014) summarize the ecologically and biologically significant attributes of the Canso Ledges ESBA. Although the ESBA wraps around the Canso peninsula and thus includes areas along the south shore of the peninsula that are outside of the area potentially impacted by the Project, many of these attributes specifically reference Chedabucto Bay. The attributes below are extracted from Hastings *et al.* (2014):

Uniqueness

- Chedabucto Bay is unique in its size and depth.
- A tongue of deep water is present on northern shore of the peninsula.
- The Bay supports rare coastal habitat for Northern Shrimp.

Aggregation

- The mouth of Chedabucto Bay has been noted for its abundance and diversity of fish.
- Historic importance for Atlantic Cod (Endangered – COSEWIC). May still be important area for this species.
- Aggregations of Atlantic Wolffish (Special Concern – SARA), Thorny Skate (Special Concern – COSEWIC), and Winter Skate (Threatened – COSEWIC).
- Inshore concentration of Fin Whale (Special Concern – SARA).
- Significant aggregations of scoter spp., merganser spp., American Black Duck, Common Eider, and Purple Sandpiper.
- High concentrations of the rockweed *Fucus* spp around the Canso peninsula and into Chedabucto Bay.
- Because of its strong depth gradient, the Bay is a hotspot for invertebrate diversity.

Fitness Consequences

- The Bay is potentially important juvenile areas for sand lance spp., hake spp., and Grubby.

- Formerly a significant spring and fall spawning area for Atlantic Herring.
- Overwintering area for Atlantic Herring.

6.7 Species at Risk and Species of Conservation Concern

Under the federal *Species at Risk Act* (SARA), the COSEWIC determines whether a species is at risk. Following a period of public and stakeholder review, the Governor in Council may recommend to the Minister of Environment whether the species will be protected under SARA. Species at Risk (SAR) are those classified as Extirpated, Endangered, Threatened, or Special Concern in SARA Schedule 1. Once listed, measures for protection and recovery of the species are implemented. Under SARA (SARA section 32 and 33), prohibitions apply to species listed in Schedule 1 except for the species of Special Concern. As of September 1 2014, there were 42 species listed under SARA (Schedule 1) for NS (www.sararegistry.gc.ca).

On the provincial level, species listed as Endangered, Threatened, or Vulnerable under the *Nova Scotia Endangered Species Act* (NSESA) are also considered to be SAR. Since the latest amendment to the list of protected species in July 2013, there are 51 species listed as SAR under the NSESA.

Other organizations apply their own criteria to species considered threatened by human activity. These include species which are ranked in the General Status of Wild Species in Canada for Nova Scotia (GSWSC-NS, www.wildspecies.ca) as 1 (At-Risk), 2 (May be at Risk) or 3 (Vulnerable). Such species are often referred to as Species of Conservation Concern (SOCC), not SAR, since they may be at risk but are not yet legally protected federally or provincially. The Atlantic Canada Conservation Data Centre (ACCDC) also provides ranks (known as S-ranks) for species occurring in the Atlantic Provinces.

Descriptions of the ranking systems used by COSEWIC, SARA, NSESA, the GSWSC, and ACCDC are provided in **Appendix N** (Attachment A).

SAR and SOCC belong to numerous taxonomic groups, including lichens, vascular plants, fish, amphibians, reptiles, mammals, birds, molluscs, odonates, and butterflies. To obtain data on SOCC potentially occurring in the area, data requests were submitted to the ACCDC and the Nova Scotia Museum of Natural History (NSMNH). Data provided in 2010 for a standard 100 km radius around Black Point by the ACCDC indicated the potential for occurrence of a number of SAR and numerous SOCC in the region (**Appendix N** Attachment B) though few have actually been observed in the Project area (Section 6.4- **Appendix E**). An updated data request in 2014, using the new five km radius as required by NSDNR, resulted in only 4 SOCC from the area (**Appendix N** Attachment C). Data requests to the NSMNH resulted in reports of two plant and 21 bird species of conservation concern in the area around the Black Point site (**Appendix N** Attachment D).

To examine the potential for SAR and SOCC species in the area encompassing the Black Point site, species listed as SAR or SOCC in NS under SARA, COSEWIC, NSESA, or the GSWSC for Nova Scotia or the Atlantic Ocean (marine species) were summarized by taxonomic group in a "Priority Species List" (Step 1, NSE 2009). Note that the General Status of Wild Species in Canada for Nova Scotia list has replaced the NSDNR colour ranking system, and is to be used in its stead (M. Elderkin, NSDNR 2013, pers. comm.). Also, while the ACCDC determines status rankings for species in the Atlantic Canadian provinces, these ranks are not considered when preparing the Priority List, as directed by NSE (2009). Instead, ACCDC data is used late in this process as a source of information on uncommon or rare species reported from the area.

In order to determine the potential for occurrence of these species in the Project area, a two-step evaluation process according to NSE (2009) including habitat modelling was carried out as described below.

Species Distribution

Priority species were evaluated concerning their presence in the broad geographic area of the proposed Project (Step 2, NSE 2009), using information on previously recorded sightings obtained from COSEWIC, NSMNH, ACCDC, and NBSDNR's Significant Habitats (SigHab) databases (when applicable). Sources also included previously completed reports that summarized published and unpublished listings of occurrences of rare species and distribution maps from a variety of literary sources such as *Roland's Flora of Nova Scotia* (Zinck 1998). Data received from ACCDC for a five km radius in 2014 and a 100 km radius in 2010 is provided in (**Appendix N** Attachments B and C), and data received from the NSMNH for the area of the Black Point site in (**Appendix N** Attachment D).

All data was then used to compile a Short List of Priority Species that occurs in the general geographical area of the Project, i.e., Eastern NS (**Appendix N** Attachment E). Species whose known distribution range does not include eastern NS were excluded from the short list.

Habitat Preferences

The species listed in the Short List of Priority Species were then reviewed with respect to their habitat requirements (Step 3, NSE 2009). Those species which exist in, or utilize habitat types found within the Project footprint or immediate surrounding areas, were summarized by taxonomic group as "species with potential to be present at the Project site" (see below). Suitable habitat was scanned for indications of the presence of these priority species during field surveys as indicated below. Results of the priority species evaluation process are provided in the following sections.

It should be noted that it is possible that other species of concern exist within the area without previously recorded sightings. Therefore, the potential presence of other priority species for which suitable habitat occurred within the Project area was considered during field surveys.

6.7.1 Terrestrial SAR and SOCC

Terrestrial species groups assessed within this document include vascular plant, lichens, terrestrial mammals, reptiles, amphibians, birds, and select invertebrates (Lepidopterans and Odonates). Each of these groups is discussed in the following subsections.

The ACCDC was consulted for records species of conservation concern from the area encompassing the project sites. In 2010, when the initial field work for this project was done, NSDNR required all such databases searches utilize a 100 km radius around the Project site. In 2014, however, when an updated ACCDC search was requested, this requirement had been reduced to only a 5.0 km radius, and therefore the more recent list is much shorter.

6.7.1.1 Vascular Plant SAR and SOCC

A total of 295 species, subspecies and varieties of vascular plants are considered to be SAR in NS (i.e., listed under SARA, COSEWIC (2013) or the NSESA), or are listed as SOCC (i.e.,

ranked as 1, 2, or 3 in the GSWSC for Nova Scotia). For definitions of the conservation rankings, see **Appendix N** Attachment A).

A short-list of Priority Flora Species (SARA, COSEWIC, NSESA, and Canada General Status List for Nova Scotia) was assembled based on known geographic distribution of priority species in the geographic region around the Project area, using data received from ACCDC, the NSMNH and distribution maps in Zinck's *Flora of Nova Scotia* (1998). The NSDNR Significant Habitats database no longer contains information on vascular plant and lichen SAR and SOCC within NS any longer (NSDNR 2012), so this was not consulted.

A total of 80 vascular plant priority species, subspecies and varieties were identified as having potential to occur in the region of eastern NS (Step 2, NSE (2009b)) (**Appendix N** Attachment E). The 2014 ACCDC database search provided no records of any vascular plant species of conservation concern for a radius of five km around the Project site (**Appendix N** Attachment C).

6.7.1.1.1 Vascular Plant SAR and SOCC Potentially Occurring on the Black Point Site

Habitat modelling was applied in order to estimate the potential presence of the 80 short-listed vascular plants in the Project footprint or immediate surrounding areas (Step 3, NSE (2009); see **Appendix E**). Based on information in Zinck (1998) and Hinds (2000), suitable habitat appears to be available on the Black Point site for over half (48 of 80) of the short-listed vascular plant species.

No priority species were reported by ACCDC within five km of the Black Point site in 2014 (**Appendix N** Attachment C). The NSMNH provided records of two vascular plant SOCC for the area around the Project footprint (**Appendix N**, Attachment D).

Priority species with habitat requirements which may be met by habitats on the Project site are listed in Table 6.7.1.

**Table 6.7-1:
Priority Vascular Plant Species Potentially Present**

	SCIENTIFIC NAME	COMMON NAME	STATUS LISTS	HABITAT ¹
1	<i>Ageratina altissima</i>	White Snakeroot	GSWSC-NS= 2 (May Be At Risk)	Clearings, thickets, and moist woods.
2	<i>Betula michauxii</i>	Newfoundland Dwarf Birch	GSWSC-NS= 3 (Sensitive)	Peat and sphagnum bogs.
3	<i>Botrychium simplex</i>	Least Moonwort	GSWSC-NS= 3 (Sensitive)	Lakeshores, or mossy edges of streams or waterfalls.
4	<i>Cardamine pratensis</i>	Cuckoo Flower	GSWSC-NS= 2 (May Be At Risk)	Meadows, low fields and moist areas.
5	<i>Carex adusta</i>	Lesser Brown Sedge	GSWSC-NS= 3 (Sensitive)	Dry open woods, gravels, rocks, and clearings. Also in acidic soils.
6	<i>Carex alopecoidea</i>	Foxtail Sedge	GSWSC-NS= 2 (May Be At Risk)	Moist, overgrown, clear-cut woods near coast
7	<i>Carex castanea</i>	Chestnut Sedge	GSWSC-NS= 2 (May Be At Risk)	Swamps and wet meadows, cliff crevices and ledges.
8	<i>Carex comosa</i>	Bearded Sedge	GSWSC-NS= 3 (Sensitive)	Rich marshes
9	<i>Carex haydenii</i>	Hayden's Sedge	GSWSC-NS= 2 (May Be At Risk)	Wet Meadows and rocky shores.

	SCIENTIFIC NAME	COMMON NAME	STATUS LISTS	HABITAT ¹
10	<i>Carex peckii</i>	Peck's Sedge	GSWSC-NS= 2 (May Be At Risk)	Uncommon on rocky slopes, clearing and dry woods, often on calcareous soils.
11	<i>Carex rostrata</i>	Narrow-leaved Beaked Sedge	GSWSC-NS= 2 (May Be At Risk)	Wet meadows, swales and around boggy pond margins.
12	<i>Carex tenera</i>	Tender Sedge	GSWSC-NS= 3 (Sensitive)	Meadows, woodlands, moist or dry openings.
13	<i>Comandra umbellata</i>	Bastard's Toadflax	GSWSC-NS= 2 (May Be At Risk)	Damp, sandy areas, dunes and exposed headlands; Open coniferous woods.
14	<i>Cornus suecica</i>	Swedish Bunchberry	GSWSC-NS= 3 (Sensitive)	Sphagnum depressions in barrens, gravelly shores, and dry exposed headlands.
15	<i>Crassula aquatic</i>	Water Pygmyweed	GSWSC-NS= 3 (Sensitive)	Brackish, muddy shore and muddy flats and borders of muddy ponds near the coast.
16	<i>Eleocharis flavescens</i>	Yellow Spikerush	GSWSC-NS= 3 (Sensitive)	Bogs, cold springs, dry stream banks, lake and pond margins, maritime mud flats, marshes, moist meadows, swamps;
17	<i>Eleocharis ovate</i>	Ovate Spikerush	GSWSC-NS= 3 (Sensitive)	Fresh, often drying shores, lake and stream beds, bogs, tidal estuaries, disturbed places;
18	<i>Empetrum eamesii</i>	Pink Crowberry	GSWSC-NS= 3 (Sensitive)	Exposed headlands on top of lichen-bearing rocks with thin soil.
19	<i>Epilobium coloratum</i>	Purple-veined Willowherb	GSWSC-NS= 3 (Sensitive)	Low-lying ground, springy slopes, and similar locations.
20	<i>Eriophorum gracile</i>	Slender Cottongrass	GSWSC-NS= 3 (Sensitive)	Wet peat and inundated shores.
21	<i>Fallopia scandens</i> (syn. <i>Polygonum scandens</i>)	Climbing False Buckwheat	GSWSC-NS= 3 (Sensitive)	Low habitats
22	<i>Fraxinus nigra</i>	Black Ash	GSWSC-NS= 3 (Sensitive), NSESA= Threatened	Low ground, damp woods, and swamps.
23	<i>Fraxinus pennsylvanica</i>	Red Ash	GSWSC-NS= 2 (May Be At Risk)	Near lakes and pond or in other low lying areas.
24	<i>Goodyera repens</i>	Lesser Rattlesnake-plantain	GSWSC-NS= 3 (Sensitive)	Under conifers, typically occurring singly.
25	<i>Hypericum dissimulatum</i>	Disguised St John's-wort	GSWSC-NS= 3 (Sensitive)	On shores and in damp open areas (Hinds, 2000); mostly shores.
26	<i>Hypericum majus</i>	Large St. John's-wort	GSWSC-NS= 2 (May Be At Risk)	Wet or dry open soil. (Hinds 2000: damp open areas)
27	<i>Iris prismatica</i>	Slender Blue Flag	GSWSC-NS= 2 (May Be At Risk)	Wet ground near the coast.
28	<i>Isoetes acadensis</i>	Acadian Quillwort	GSWSC-NS= 3 (Sensitive)	Water up to 1 m deep, bordering lakes or ponds, and occasionally along rivers.
29	<i>Juncus alpinoarticulatus</i>	Alpine Rush	GSWSC-NS= 2 (May Be At Risk)	Wet meadows, sandy and gravelly, often calcareous shores, fens, and clayey pools over rock
30	<i>Listera australis</i>	Southern Twayblade	GSWSC-NS= 2 (May Be At Risk)	Sphagnum moss bogs or damp woods. Always near small spruce or tamarack.
31	<i>Malaxis monophyllos</i>	White Adder's-mouth	GSWSC-NS= 2 (May Be At Risk)	Moss cushions and wet, mossy cliff edges, where there is little competition from other plant species
32	<i>Pedicularis palustris</i>	Marsh Lousewort	GSWSC-NS= 2 (May Be At Risk)	Marshes and meadows.
33	<i>Platanthera macrophylla</i> (syn. <i>Platanthera orbiculata</i> var. <i>macrophylla</i>)	Large Round-leaved Orchid	GSWSC-NS= 3 (Sensitive)	Damp woods in deep shade

	SCIENTIFIC NAME	COMMON NAME	STATUS LISTS	HABITAT ¹
34	<i>Potamogeton nodosus</i>	Long-leaved Pondweed	GSWSC-NS= 2 (May Be At Risk)	Pond and streams
35	<i>Proserpinaca pectinata</i>	Comb-leaved Mermaidweed	GSWSC-NS= 3 (Sensitive)	Wet savannahs, sphagnum swales, and the sandy, gravelly, or muddy borders of lakes or ponds
36	<i>Ranunculus pensylvanicus</i>	Pennsylvania Buttercup	GSWSC-NS= 2 (May Be At Risk)	Muddy shores and moist meadows (Hinds 2000). Richer moist shores and sometimes disturbed ground.
37	<i>Rudbeckia laciniata</i>	Cut-leaved Coneflower	GSWSC-NS= 3 (Sensitive)	Swales, the edges of swamps or in gullies, in small colonies.
38	<i>Salix pedicellaris</i>	Bog Willow	GSWSC-NS= 3 (Sensitive)	Swampy thickets, poorly drained soils, bogs, and heavy soils.
39	<i>Schoenoplectus americanus</i> (SYN. <i>Scirpus americanus</i>)	Olney's Bulrush	GSWSC-NS= 3 (Sensitive)	Brackish marshes, and sometime in bogs near the coast. Forms colonies on wet sand around depressions where sand is rather salty.
40	<i>Senecio pseudoarnica</i>	Seabeach Ragwort	GSWSC-NS= 3 (Sensitive)	Gravelly seashores.
41	<i>Sparganium hyperboreum</i>	Northern Burreed	GSWSC-NS= 3 (Sensitive)	Peaty pools.
42	<i>Symphyotrichum boreale</i>	Boreal Aster	GSWSC-NS= 3 (Sensitive)	Gravelly soil and lake beaches, along streams and the edges of bogs.
43	<i>Teucrium canadense</i>	Canada Germander	GSWSC-NS= 3 (Sensitive)	Gravel seacoasts, the crest of the beach, beyond the reach of the tide.
44	<i>Vaccinium boreale</i>	Northern Blueberry	GSWSC-NS= 2 (May Be At Risk)	Exposed headlands and barrens.
45	<i>Vaccinium caespitosum</i>	Dwarf Bilberry	GSWSC-NS= 3 (Sensitive)	Rocky cliffs and crevices. Dry or wet acidic sites from sea level to 3800 m.
46	<i>Vaccinium avilifolium</i>	Oval-leaved Bilberry	GSWSC-NS= 2 (May Be At Risk)	Moist coniferous woods to an elevation of 2100 m.
47	<i>Vaccinium uliginosum</i>	Alpine Bilberry	GSWSC-NS= 3 (Sensitive)	Dry or wet, organic or inorganic acid soils. Tolerant of high copper concentrations.
48	<i>Viola nephrophylla</i>	Northern Bog Violet	GSWSC-NS= 3 (Sensitive)	Cool mossy bogs. Borders of streams, and damp woods.

¹ Sources are Zinck (1998), Hinds (2000) and personal communications (2013) from Sean Blaney, ACCDC

6.7.1.1.2 Vascular Plant SAR and SOCC Confirmed to Occur on the Black Point Site

Field surveys of a variety of habitats in the Project area were carried out in 2010 and 2014 in order to identify vascular plant SAR and SOCC with early and late phenology. A vascular plant inventory based on those surveys amended by current (2014) conservation ranks is provided in Section 6.4, **Appendix E**. During the field surveys, only two vascular plant SOCC were found (Table 6.7.2).

**Table 6.7-2:
Vascular Plant SOCC Confirmed to Occur on the Site**

	Common Name	Scientific Name	Status	Habitat Preferences ¹
1	Northern Commandra	<i>Geocaulon lividum</i>	Canada General Status List of Wild Species= 3 (Sensitive)	Sterile soils and damp sands, in acid or peaty areas.
2	Southern Twayblade	<i>Listera australis</i>	Canada General Status List of Wild Species= 2 (May be at Risk)	Sphagnum moss bogs or damp woods. Always near small spruce or tamarack.

¹ Sources are Hinds (2000) and personal communications from Sean Blaney, ACCDC

6.7.1.2 Lichen (Non-vascular Flora) SAR and SOCC

According to ACCDC, Southern Twayblade (*Listera australis*) was reported four times within a 100 km radius, with the closest location being 24 +/-10 km away. Note that ACCDC does not provide exact locations in order to protect uncommon species. ACCDC has a single record for Northern Commandra (*Geocaulon lividum*), also 24 +/-10 km from the Black Point site (ACCDC 2010, **Appendix N** Attachment B).

A total of 65 species of lichens are considered to be SAR, *i.e.*, listed under SARA, COSEWIC (2013) or the *NSESA*, or listed as SOCC (*i.e.*, ranked 1, 2, or 3 in the Canada General Status List for NS. For definitions of the conservation rankings see **Appendix N** Attachment A.

A short-list of priority species was assembled based on known occurrences of priority species in the geographic region, using data received from ACCDC and the NSMNH and professional knowledge (Step 2, NSE 2009). Lichens are no longer listed in the NSDNR SigHab database (NSDNR 2012c). The resulting table listing the 46 lichen species with potential to occur in eastern Nova Scotia, along with their habitat requirements is provided in **Appendix N** Attachment E. While *Sclerophora peronella* is unlikely to occur in the Project area because its known distribution is limited to Cape Breton Highlands National Park, it was retained in the short-list using a precautionary principle.

ACCDC had no records for any lichen SOCC within a five km radius of the Black Point site (ACCDC 2014, **Appendix N** Attachment C). An earlier ACCDC request conducted in 2010 resulted in 31 records of a single lichen species (Boreal Felt Lichen) considered to be of conservation concern within a radius of 100 km around the Project site (ACCDC 2010, **Appendix N** Attachment B). The NSMNH does not have any records for rare lichens in the Project area (**Appendix N** Attachment D).

6.7.1.2.1 Lichen SAR and SOCC Potentially Occurring on the Black Point Site

Of the 47 lichen priority species identified for the region (Step 2), thirteen have the potential to occur on site (Step 3, NSE 2009) based on their habitat requirements. These are outlined in Table 6.7.3. The lichen priority species encompass ground-dwelling (terricolous), rock-dwelling (saxicolous) and tree-dwelling (corticolous) lichens.

**Table 6.7-3:
Priority Lichen Species with Potential to Occur in the Area**

	Common Name	Scientific Name	Status	Habitat Preferences ¹
1	<i>Polychidium muscicola</i>	Eyed Mossthorns Woollybear Lichen	GSWSC-NS = 2 (May be at Risk)	Among mosses on exposed or shaded rocks. Occasionally on ground or at base of trees
2	<i>Punctelia appalachensis</i>	Appalachian Speckleback Lichen	GSWSC-NS = 3 (Vulnerable)	On deciduous trees
3	<i>Ramalina thrausta</i>	Angelhair Ramalina Lichen	GSWSC-NS = 3 (Vulnerable)	On trees, rarely rocks
4	<i>Sticta fuliginosa</i>	Peppered Moon Lichen	GSWSC-NS = 3 (Vulnerable)	Mossy bark, rarely mossy rock
5	<i>Sticta limbata</i>	Powdered Moon Lichen	GSWSC-NS = 2 (May be at Risk)	Mossy bark and rock, especially in coastal forest
6	<i>Umbilicaria polyphylla</i>	Petaled Rocktripe Lichen	GSWSC-NS = 3 (Vulnerable)	On nutrient -encrusted siliceous rocks
7	<i>Usnea ceratina</i>	Warty Beard Lichen	GSWSC-NS = 3 (Vulnerable)	Usually on trees, occasionally rocks, near moist lakesides, wetlands or coastal habitats
8	<i>Usnea flammea</i>	Coastal Bushy Beard Lichen	GSWSC-NS = 3 (Vulnerable)	On trees and rocks
9	<i>Usnea flavocardia</i>	Blood-splattered Beard Lichen	GSWSC-NS = 3 (Vulnerable)	On trees, usually in coastal areas
10	<i>Usnea mutabilis</i>	Bloody Beard Lichen	GSWSC-NS = 3 (Vulnerable)	On trees in deciduous and pine forests.
11	<i>Usnea scabrata</i>	Straw Beard Lichen	GSWSC-NS = 3 (Vulnerable)	On conifers in forests or open habitat
12	<i>Usnea substerilis</i>	Embossed Beard Lichen	GSWSC-NS = 2 (May be at Risk)	On trees
13	<i>Usnocetraria oakesiana</i> (syn. <i>Cetraria/Allocetraria oakesiana</i>)	Yellow Band Lichen	GSWSC-NS = 2 (May be at Risk)	On both conifers and some hardwoods, occasionally on rocks

¹ Sources are Brodo *et al.* (2001), Hinds and Hinds (2000)

Of the 13 remaining lichen Priority Species, one species, Boreal Felt Lichen (SARA, COSEWIC and NSESA Endangered, GSWSC= 1 (At Risk)) is considered most likely to occur in the general area, because ACCDC has reported 31 observations within 100 km distance (ACCDC 2010, see **Appendix N** Attachment B).

Boreal Felt Lichen

Boreal Felt Lichen grows on the bark of mature Balsam Fir trees in cool, humid habitats. Wet coniferous forests, usually in or near wetlands, on north to east facing slopes near the coast are preferred (Cameron and Neily 2008). NSE Protected Areas Branch has prepared predictive maps indicating polygons of potential BFL habitat in Nova Scotia based on a heuristic model (NSE 2008). These potential habitats categorize potential Boreal Felt Lichen habitat according to level of suitability (Low, Medium, and High). The maps indicate that there is no potential Boreal Felt Lichen habitat within the footprint of the Black Point site. However, there are nine small polygons of potential Boreal Felt Lichen habitat within a two km radius of the Project site (Figure 6.7.1). One polygon of high suitability (Category 1) habitat is located about 500m south of the Project site. Five areas of Medium suitability and four of low suitability also occur within

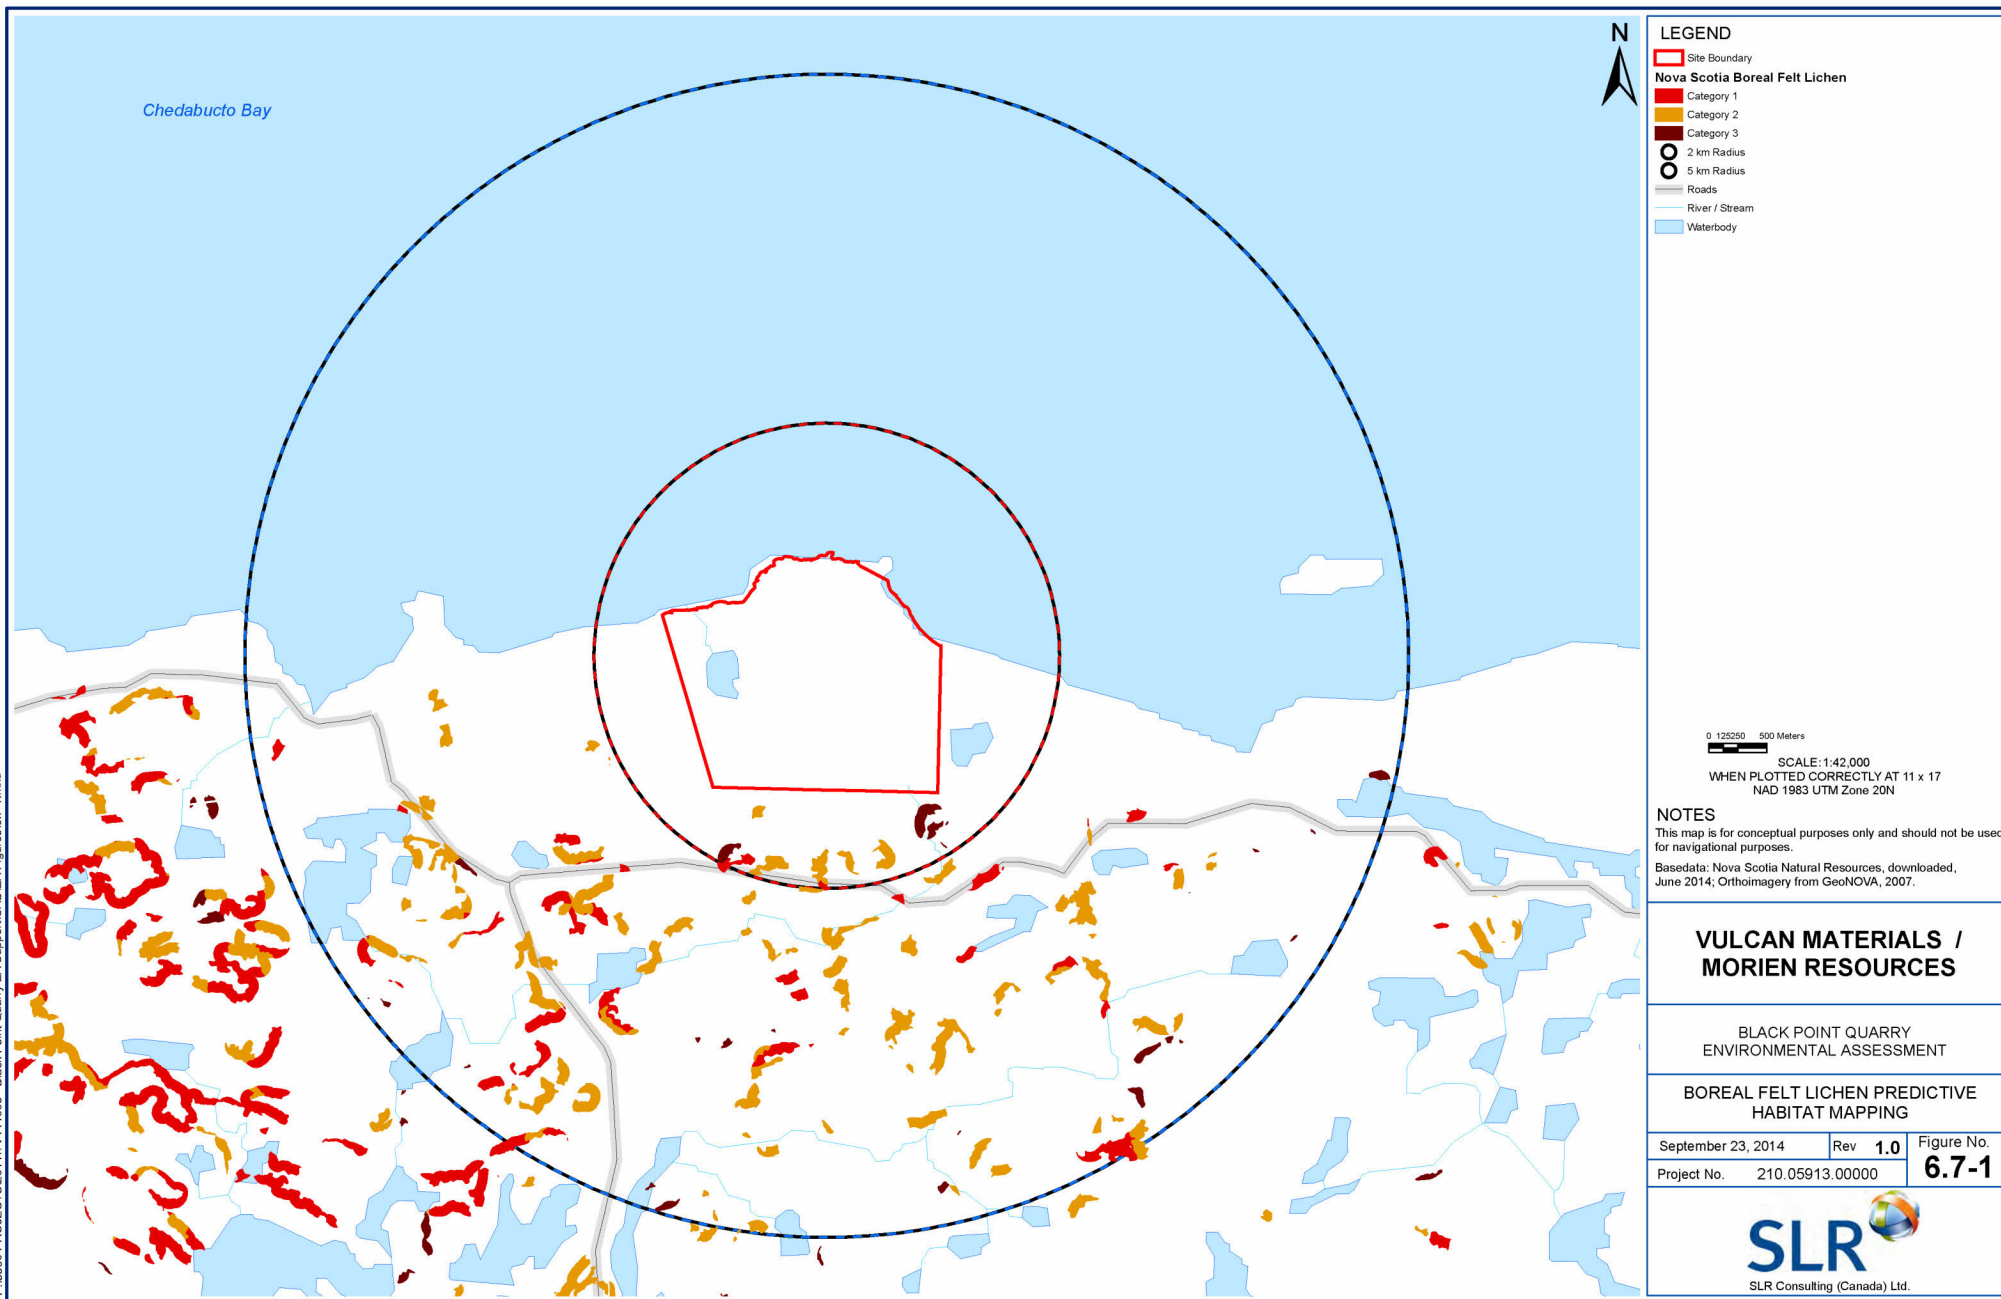

about 700 m of the southern boundary of the Project site. All of these areas are considered to be well out of range of dust or other potential effects of quarry activities.

In addition to looking for Boreal Felt Lichen on the site directly, the available habitat was evaluated concerning suitability as habitat for this species. Balsam fir, the preferred host species for Boreal Felt Lichen occurs on the Project site, however, the microclimatic conditions required by this species apparently were not met at the Black Point site. Wet forests on north to east facing slopes were not encountered. No Boreal Felt Lichen was found on the site during targeted lichen surveys in 2010 or 2014 (Section 6.4 and **Appendix E**).

6.7.1.2.2 Lichen SAR and SOCC Confirmed to Occur on the Black Point Site

A lichen survey of the Black Point site was carried out in August 2010 and again in August 2014 targeting all lichen SAR or SOCC in all potential habitats on the Project site. In addition, indicator species and any cyanolichens were of interest and were included in the surveys, as their habitat requirements are similar to the habitat requirements of the priority species as indicated in **Appendix E**. Survey methods and photos are provided in Section 6.4 and **Appendix E**.

A total of four lichen SOCC were found on the Black Point site in 2010 and 2014. Much of the observed forest habitat is likely not conducive to the presence of rare lichen species due to previous disturbance. The four lichen SOCC occurring on the Project site are outlined in Table 6.7.4.

**Table 6.7-4:
Lichen SOCC Confirmed to Occur on the Site**

	Common Name	Scientific Name	General Status of Wild Species in Canada-NS 2010 Rank	Habitat Preferences ¹
1	<i>Cladonia stygia</i>	Black-footed Reindeer Lichen	3- Vulnerable	Open bog
2	<i>Nephroma bellum</i>	Naked Kidney Lichen	3- Vulnerable	Forested wetlands on Red Maple
3	<i>Usnea flammea</i>	Coastal Bushy Beard Lichen	3- Vulnerable	Conifers
4	<i>Ramalina thrausta</i>	Angel Hair Ramalina Lichen	3- Vulnerable	On trees, rarely rocks

¹ Sources are Brodo *et al.* (2001), Hinds and Hinds (2000).

Note that the 2010 fieldwork summary report prepared for this Project (**Appendix E**), another lichen species thought to be of conservation concern was reported. However, this species, *Peltigera leucophlebia*, which was yellow listed by the now-discarded NSDNR General Status List, is currently listed as Secure on the Canada General Status of Wild Species List for Nova Scotia, and, as it is not listed on other conservation status lists for NS, is no longer considered a SOCC.

All four lichen SOCC species likely occur within the Project footprint.

6.7.1.3 Avifauna SAR and SOCC

A total of 93 species of birds are listed as SAR in NS under SARA, COSEWIC, NSESA, or listed as SOCC by the GSWSC for NS (updated in 2010). All of these were included in the initial Priority Species List. For definitions of the conservation rankings see **Appendix N** Attachment A. In addition, all raptors are protected under the *Nova Scotia Wildlife Act (NSWA)*. While a number of the priority species have not been recorded in eastern NS, there is potential for many of the priority species to be found in the Project area based on available habitat, either as breeding birds or during migration. A list of bird species of conservation concern (81 in total) that have potential to occur in the Project area based on habitat requirements and distribution is provided in **Appendix N** Attachment E.

6.7.1.3.1 Avifauna SAR and SOCC Potentially Occurring on the Black Point Site

To gain further information on bird species potentially occurring on the Black Point site, records of bird SAR and SOCC in the Project area were obtained from field surveys conducted in 2010 and from existing databases. Data were obtained from the Maritimes Breeding Bird Atlas and Environment Canada's Canadian Wildlife Service (EC-CWS), while the NatureCounts database was consulted for additional information sightings on rare and colonial species. The NSMNH provided information on twenty-one avifauna priority species reported to occur in the area surrounding the Project site.

ACCDC results for priority species within a five km buffer around the Project area were obtained in 2014, while records for a wider radius (100 km) were obtained in 2010. Records of wintering

waterfowl and seabird colonies were obtained from EC-CWS. EC-CWS also provided information regarding records of American Oystercatcher (*Haematopus palliatus*) breeding on Grassy Island (EC-CWS pers. comm. 2014).

Of the 81 avian SOCC potentially occurring in the Project area (eastern mainland NS), just over half (43) are considered to have suitable habitat available on the Black Point site. These are listed in Table 6.7.5.

**Table 6.7-5:
Avian Priority Species Potentially Present in the Area.**

	Scientific Name	Common Name	Status Lists	Habitat Preferences ¹
1	<i>Actitis macularius</i>	Spotted Sandpiper	GSWSC-NS=3 (Sensitive)	Breeds near water in a variety of habitats, including shorelines, grasslands and forests. Found in both coastal and freshwater habitats during migration.
2	<i>Asio flammeus</i>	Short-eared Owl	COSEWIC=Special Concern SARA=Special Concern / Schedule 1 GSWSC-NS=2 (May Be At Risk)	Usually found in open country supporting cyclic small mammals (voles, lemmings), large expanses of grasslands, heathlands, shrub-steppe, tundra or agricultural areas. Nesting: dry sites with enough vegetation to conceal incubating female.
3	<i>Bucephala islandica</i>	Barrow's Goldeneye	COSEWIC=Special Concern SARA=Special Concern / Schedule 1 GSWSC-NS=1 (At Risk)	Breeding appear to be restricted to high elevation lakes north of St. Lawrence Estuary and Gulf. Eastern Canada populations have dwindled in recent years as a result of habitat loss due to fish introduction, logging and contamination.
4	<i>Calidris maritima</i>	Purple Sandpiper	GSWSC-NS=3 (Sensitive)	Coastal environments.
5	<i>Calidris pusilla</i>	Semipalmated Sandpiper	GSWSC-NS=3 (Sensitive)	Breeds in subarctic tundra; found in coastal habitats during migration.
6	<i>Cardellina</i> (syn. <i>Wilsonia</i>) <i>canadensis</i>	Canada Warbler	COSEWIC=Threatened SARA=Endangered/ Schedule 1 NESA=Endangered GSWSC- NS=1 (At Risk)	Most abundant in moist, mixed forests with a well-developed understory, dense nest site cover. Often near open water. Nesting: Typically on or near the ground, often on slopes, knolls, in earthen banks, or rocky areas.
7	<i>Cathartes aura</i>	Turkey Vulture	GSWSC-NS=3 (Sensitive)	Preferred habitat includes farmland with pasture and abundant carrion close to undisturbed forested areas for perching, roosting, and nesting. This species nests in dark recesses beneath boulders, on cliff ledges, in hollow trees, logs, and stumps, and in abandoned buildings

	Scientific Name	Common Name	Status Lists	Habitat Preferences ¹
8	<i>Charadrius vociferus</i>	Killdeer	GSWSC-NS=3 (Sensitive)	A variety of open habitats, including sandbars, mudflats, heavily grazed pastures, cultivated fields, athletic fields, airports, golf courses, gravelled lots, and gravelled rooftops
9	<i>Chordeiles minor</i>	Common Nighthawk	COSEWIC=Threatened SARA=Threatened/ Schedule 1 GSWSC-NS=1 (At Risk)	Coastal sand dunes and beaches, logged or slash-burned areas of forest sites, woodland clearings, grassland habitat, farm fields, open forests, rock outcrops, and flat gravel rooftops. Nesting: Nests in open areas on the ground.
10	<i>Contopus cooperi</i>	Olive-sided Flycatcher	COSEWIC=Threatened SARA=Threatened /Schedule 1 NESA=Threatened GSWSC-NS=1 (At Risk)	Along forest edges and openings with tall snags for foraging and singing. Nesting: generally well out toward tip of horizontal branch in coniferous tree.
11	<i>Contopus virens</i>	Eastern Wood Peewee	COSEWIC=Special Concern GSWSC-NS=3 (Sensitive)	Damp boreal forests, spruce bogs, swamps, coniferous forests, wet areas with sphagnum-moss ground cover
12	<i>Dendroica castanea</i>	Bay-breasted Warbler	GSWSC-NS=3 (Sensitive)	Spruce-fir forests
13	<i>Dendroica striata</i>	Blackpoll Warbler	GSWSC-NS=3 (Sensitive)	Deciduous and mixed forests, damp woodlands
14	<i>Dendroica tigrina</i>	Cape May Warbler	GSWSC-NS=3 (Sensitive)	Mixed and deciduous forests with thick undergrowth, rhododendron thickets, beech and maple forests
15	<i>Dumetella carolinensis</i>	Gray Catbird	GSWSC-NS=2 (May Be At Risk)	Open woodlands, suburban areas, thickets
16	<i>Empidonax flaviventris</i>	Yellow-bellied Flycatcher	GSWSC-NS=3 (Sensitive)	Birch forests, bogs, edges of marshes, damp thickets of alder or willows
17	<i>Euphagus carolinus</i>	Rusty Blackbird	COSEWIC=Special Concern SARA=Special Concern /Schedule 1 GSWSC-NS=2 (May Be At Risk)	Frequents cool habitats in forest openings, including spruce bogs, swamps, and damp alder swales. Nesting: In trees and shrubs, 0.5 m to 6 m above ground or over water.
18	<i>Gallinago delicata</i> (form. <i>G. gallinago</i>)	Wilson's Snipe	GSWSC-NS=3 (Sensitive)	Sedge bogs, fens, alder or willow swamps, and pond and river edges.
19	<i>Gavia immer</i>	Common Loon	GSWSC-NS=2 (May Be At Risk)	Prefers lakes larger than 24 ha with clear water, an abundance of small fish, numerous small islands, and an irregular shoreline. Nesting: ground-nesting; prefers to nest on islands.

	Scientific Name	Common Name	Status Lists	Habitat Preferences ¹
20	<i>Haematopus palliatus</i>	American Oystercatcher	GSWSC-NS=5 (Undetermined) ²	Tied to coastal areas during breeding and non-breeding intervals, bound by prey specialization on shellfish and other marine invertebrates. Nests primarily on sand and shell beaches, dunes, salt marsh, and occasionally rock or other surfaces, in areas with little to no vegetation. Known to breed on Grassy Island in Guysborough County (one of two known nesting areas in Canada)
21	<i>Histrionicus histrionicus</i>	Harlequin Duck	COSEWIC=Special Concern SARA=Special Concern / Schedule 1 NSESA=Endangered GSWSC-NS=1 (At Risk)	Favour marine environments, but move inland to breed. In winter, occurs along headlands where surf breaks against rocks. Feed close to rocky shorelines or skerries. Few breeding records in NS
22	<i>Numenius phaeopus</i>	Whimbrel	GSWSC-NS=3 (Sensitive)	Arctic tundra, bogs, marshes at edge of boreal forests
23	<i>Perisoreus canadensis</i>	Gray Jay	GSWSC-NS=3 (Sensitive)	Nests in often large colonies, under rock ledges, highway culverts, bridges, and buildings
24	<i>Phalacrocorax carbo</i>	Great Cormorant	GSWSC-NS=3 (Sensitive)	Rocky islands, cliffs facing water, stands of trees near water
25	<i>Pheucticus ludovicianus</i>	Rose-breasted Grosbeak	GSWSC-NS=3 (Sensitive)	Woodland edges, weedy fields, thickets
26	<i>Picoides arcticus</i>	Black-backed Woodpecker	GSWSC-NS=3 (Sensitive)	Open woodlands, mature forests
27	<i>Pinicola enucleator</i>	Pine Grosbeak	GSWSC-NS=2 (May Be At Risk)	Open woodlands, conifer forests
28	<i>Poecile hudsonicus</i>	Boreal Chickadee	GSWSC-NS=3 (Sensitive)	Boreal forests
29	<i>Riparia riparia</i>	Bank Swallow	COSEWIC= Threatened GSWSC-NS=2 (May Be At Risk)	Along rivers, streams, lakes, and coasts. Nesting: burrows in banks, cliffs and bluffs; may also use artificial sites such as sand and gravel quarries and road cuts.
30	<i>Regulus calendula</i>	Ruby-crowned Kinglet	GSWSC-NS=3 (Sensitive)	Coniferous and mixed forests.

	Scientific Name	Common Name	Status Lists	Habitat Preferences ¹
31	<i>Regulus satrapa</i>	Golden-crowned Kinglet	GSWSC-NS=3 (Sensitive)	Coniferous forests during breeding season; in winter, may be found in coniferous, mixed and deciduous forests.
32	<i>Sayornis phoebe</i>	Eastern Phoebe	GSWSC-NS=3 (Sensitive)	Open deciduous and coniferous woodlands
33	<i>Spinus pinus</i>	Pine Siskin	GSWSC-NS=3 (Sensitive)	Generally inhabits coniferous or mixed coniferous-deciduous forests
34	<i>Sterna dougallii</i>	Roseate Tern	COSEWIC=Endangered SARA=Endangered /Schedule 1 NESA=Endangered GSWSC-NS=1 (At Risk)	Colonies sparsely scattered on southern shore of NS (Brothers Islands, Grassy Island, and Country Island Complex)
35	<i>Sterna hirundo</i>	Common Tern	GSWSC-NS=3 (Sensitive)	Throughout NS, particularly the southern coast and Cape Breton.
36	<i>Sterna paradisaea</i>	Arctic Tern	GSWSC-NS=2 (May Be At Risk)	Lower Bay of Fundy, south shore of mainland NS, south and east shores of Cape Breton Island
37	<i>Sturnella magna</i>	Eastern Meadowlark	COSEWIC=Threatened GSWSC-NS=3 (Sensitive)	Grassland habitats
38	<i>Tachycineta bicolor</i>	Tree Swallow	GSWSC-NS=3 (Sensitive)	Open fields, meadows, marshes. Nesting: Typically in standing dead trees, or nest boxes where available.
39	<i>Tringa melanoleuca</i>	Greater Yellowlegs	GSWSC-NS=3 (Sensitive)	Breeds in muskeg, wet bogs with small wooded islands, and forests (usually coniferous) with abundant clearings. During migration, uses a variety of coastal habitats and wetlands.
40	<i>Tringa semipalmata</i>	Willet	GSWSC-NS=2 (May Be At Risk)	Breeds most commonly on salt marshes, barrier islands, and barrier beaches; also pastures and farmlands in Nova Scotia
41	<i>Tyrannus tyrannus</i>	Eastern Kingbird	GSWSC-NS=3 (Sensitive)	Open habitats, frequently along woodland edges.
42	<i>Vermivora peregrina</i>	Tennessee Warbler	GSWSC-NS=3 (Sensitive)	Open woodlands, brushy areas, cut-over and burned woods, second-growth woodlands, edges of bogs
43	<i>Wilsonia pusilla</i>	Wilson's Warbler	GSWSC-NS=3 (Sensitive)	Undergrowth in moist mature forests, dense woodlands near streams or swamps

¹ Source TBNAO (2014)

² Though not technically a SAR or SOCC, American Oystercatcher is included here at the request of EC-CWS, due to the reported presence of breeding individuals on Grassy Island, approximately 12 km east of the Project site off the town of Canso.

Although habitat may be available to these species, many have no suitable breeding or nesting habitat within the Project area; nonetheless, individuals may potentially migrate through or over-winter in the area.

6.7.1.3.2 Avifauna SAR and SOCC Confirmed to Occur on the Black Point Site

A total of 14 avian SAR and SOCC are known to occur on the Project site, having been detected on the site during filed survey by AMEC in 2010 and/or AECOM in 2011. A list of these species is provided in Table 6.7.6, along with the species status and information on known presence in the Project area. A single species, the Rusty Blackbird (*Euphagus carolinus*) is a legally-protected SAR species.

**Table 6.7-6:
Priority Avian Species Recorded on the Site**

Scientific Name	Common Name	Status Lists	Comments
<i>Dendroica castanea</i>	Bay-breasted Warbler	GSWSC-NS=3 (Sensitive)	Possible breeder.
<i>Picoides arcticus</i>	Black-backed Woodpecker	GSWSC-NS=3 (Sensitive)	Confirmed breeding in Project area.
<i>Dendroica striata</i>	Blackpoll Warbler	GSWSC-NS=3 (Sensitive)	Possible breeder.
<i>Poecile hudsonicus</i>	Boreal Chickadee	GSWSC-NS=3 (Sensitive)	Possible breeder, found year-round in Project area.
<i>Gavia immer</i>	Common Loon	GSWSC-NS= 2 (May Be At Risk)	Heard during spring surveys, outside of breeding season.
<i>Regulus satrapa</i>	Golden-crowned Kinglet	GSWSC-NS= 3 (Sensitive)	Possible breeder, found year-round in Project area.
<i>Perisoreus canadensis</i>	Gray Jay	GSWSC-NS= 3 (Sensitive)	Possible breeder; also observed during winter surveys.
<i>Phalacrocorax carbo</i>	Great Cormorant	GSWSC-NS= 3 (Sensitive)	Observed during winter surveys.
<i>Tringa melanoleuca</i>	Greater Yellowlegs	GSWSC-NS= 3 (Sensitive)	Observed in fall surveys along coast.
<i>Regulus calendula</i>	Ruby-crowned Kinglet	GSWSC-NS= 3 (Sensitive)	Possible breeder.
<i>Euphagus carolinus</i>	Rusty Blackbird	SARA= Special Concern/ Schedule 1 COSEWIC= Special Concern NESA= Endangered GSWSC-NS= 2 (May Be At Risk)	Possible breeder.
<i>Calidris pusilla</i>	Semipalmated Sandpiper	GSWSC-NS= 3 (Sensitive)	Observed in fall surveys

			along coast.
<i>Actitis macularius</i>	Spotted Sandpiper	GSWSC-NS= 3 (Sensitive)	Observed in fall surveys along coast.
<i>Empidonax flaviventris</i>	Yellow-bellied Flycatcher	GSWSC-NS= 3 (Sensitive)	Possible breeder.

Landbirds (Including Raptors and Passerines)

Breeding evidence has been recorded in the Project area for Rusty Blackbird, Boreal Chickadee, Blackpoll Warbler, Bay-breasted Warbler, Black-backed Woodpecker, Gray Jay, Golden-crowned Kinglet, Ruby-crowned Kinglet and Yellow-bellied Flycatcher (Table 6.7.6). Potential breeding habitat exists in the Project area for other landbird species of special status that were not directly observed, including Common Nighthawk, Eastern Phoebe, Pine Grosbeak, Short-eared Owl, Tennessee Warbler, Tree Swallow and Wilson's Warbler. Potentially suitable habitat exists for Black-billed Cuckoo and Willow Flycatcher, although these species are considered unlikely to occur in the Project area due to their geographic distributions.

Shorebirds

Spotted Sandpiper and Greater Yellowlegs have each been observed along the coastline in the Project area during fall migration surveys, and while both of these species may breed in the area, no breeding evidence was observed in field surveys of the Project area or in the MBBA. Fogherty Lake does not appear to provide good breeding habitat for these species, as the bank vegetation is dense and shrubby, and there are no shallow areas for wading.

The Purple Sandpiper has been reported in the general area by ACCDC (2010), the Strait of Canso CBC (National Audubon Society 2014) and during winter waterfowl surveys conducted by EC-CWS (A. Hicks, pers. comm. 2014). Purple Sandpipers breed in the Arctic; however, in the winter months, this species feeds on invertebrates along rocky shorelines throughout the province, and may be found on the coastline of the Project area.

Waterfowl and Seabirds

The Common Loon has potential to breed in freshwater lakes in the Project area; however, because Fogherty Lake is not productive and does not appear to support fish, it is considered unlikely. During the surveys for the Project, Common Loons were heard at a distance, but no breeding evidence was observed. They may utilize marine habitats off the Black Point site in winter.

Common Tern and Arctic Tern nest on coastal islands, the closest colony being on Half Island, located approximately 3 km from the Project area (EC-CWS 2014). A large tern colony supporting a significant number of breeding Roseate Terns exists in the Country Island Complex IBA (IBA 2014); this complex is composed of a number of islands and while the nearest point of this IBA is 13 km away, Country Island itself (which supports the largest number of Roseate Terns) is approximately 40 km away. Rock and Shervill (2012) state that between 18 and 53 pairs of Roseate Terns per year have been reported nesting on Country Island since surveys at this colony began in 1996, although surveys conducted in 2014 indicated that there were just 15 breeding pairs (J. Rock, pers. comm. 2014). While they do not breed in the Project area, there is slight potential for Roseate Terns to forage in the area.

One species of special status was identified during EC-CWS winter waterfowl surveys in Block 226: in 2006, two Harlequin Ducks were observed (A. Hicks, pers. comm. 2014). It is possible that some of the unidentified Goldeneye reported is Barrow's Goldeneye, which winter in small numbers off the coast of NS. The Common and Barrow's Goldeneye are very similar in appearance, and mixed flocks of the two species are known to occur. Both Barrow's Goldeneye and Harlequin Duck have been reported in the Strait of Canso CBC (National Audubon Society 2014), and both species are considered to potentially winter in the waters off the Project area.

To date, a single SAR species, the Rusty Blackbird, has been detected on the Black Point site. Rusty Blackbird was detected during a June breeding survey in 2010 by AMEC.

6.7.1.4 Mammal SARR and SOCC

6.7.1.4.1 Mammal SARR and SOCC Potentially Occurring on the Black Point Site

A total of nine terrestrial mammalian SAR or SOCC are listed by SARA, COSEWIC, NSESA, and GSWSC for NS (**Appendix N** Attachment E), of which four have potential to occur at the Project site, based on known distributions and habitat preferences (Table 6.7.7).

**Table 6.7-7:
Priority Mammal Species Potentially Present on/near the Site**

	Scientific Name	Common Name	Status	Habitat ¹
1	<i>Alces alces americana</i>	Eastern Moose- Mainland NS Population	NSESA Endangered GSWSC-NS= 1 (At Risk)	Second-growth forest, openings, swamps, lakes and wetlands
2	<i>Martes pennanti</i>	Fisher	GSWSC-NS= 3 (Sensitive)	Mixed forests
3	<i>Myotis lucifugus</i>	Little Brown Myotis	COSEWIC, SARA, NSESA Endangered GSWSC-NS= 1 (At Risk)	Forests, especially near wetlands. Hibernates in caves in colonies.
4	<i>Myotis septentrionalis</i>	Northern Myotis/ Northern Long-eared Myotis	COSEWIC, SARA, NSESA Endangered GSWSC-NS= 1 (At Risk)	Dense forest caves. Hibernates in caves.

¹ Sources are Banfield (1977), Parker (2003), Barbour and Davis (1969)

The 2014 ACCDC database request report had no records of any mammal SOCC occurring within five km of the Project area (**Appendix N** Attachment C). An earlier ACCDC request had records of two mammal SOCC occurring within the formerly required 100 km radius of the Project area (**Appendix N** Attachment B). These were mainland Moose (*Alces americanus*, 11 records within 89 km), and American Marten (*Martes americana*, three records within 92 km). Other data sources indicate that moose or signs of moose have been reported within 5 km of the centre of the Project site on 11 occasions since 1999 (M. Pulsifer, pers. comm. 2014), including visual sightings of multiple moose within the Property boundary in 2004.

The NSMNH does not have any records of mammal species of concern in the general Project area (**Appendix N** Attachment D), although they suggested the surrounding area should be evaluated for potential bat hibernacula. They also suggested that the Proponent consult with NSDNR regarding mainland Moose and Canada Lynx.

Although not reported by ACCDC or the NSMNH for the area, based on its habitat preferences and reported range in the province, the Fisher (*Martes pennanti*) may possibly occur in the region as well.

Moose

As only very low numbers of Moose occur in Eastern mainland NS, many of the Moose sightings recorded within the 100 km radius are likely from the large Cape Breton population, which is a different subspecies from western Canada (*Alces alces andersonii*) and has been introduced by humans (Parker 2003). Only the mainland population of Moose in NS is listed as Endangered by NSESA. Nonetheless, this species was retained in the short-list and subjected to the review of habitat requirements.

Moose inhabit second-growth forest, openings, swamps, lakes and wetlands (NatureServe 2013), and suitable Moose habitat occurs within the Project area. Therefore, this species is considered to have potential for presence within the Project site, and moose tracks and scat have been observed on the Project site as noted below in 6.7.1.3.2.

Fisher

Fisher (*Martes pennanti*) is listed as Vulnerable (3) by the General Status of Wild Species in Canada for NS (2010). Although not reported by ACCDC for the area, a small numbers of fishers were captured by fur harvesters in Guysborough County in 2012-2013, according to NSDNR (2014a). Fishers, though not abundant, are widespread in the province and occur in mixed and coniferous forests, typically in proximity to watercourses (Banfield 1974). Their diet consists primarily of small mammals, and they are one of the few natural predators of porcupines.

No sign of fisher was observed during surveys for this Project in 2010 or 2014. However, because there is suitable fisher habitat and abundant food (including porcupine) within the Project area, the occurrence of fisher is considered possible.

Little Brown Myotis

The Little Brown Myotis, also known as the Little Brown Bat, is a small non-migratory species which is probably the most common bat species in North America, ranging from Alaska to California (Barbour and Davis 1969). Throughout their range, Little Brown Myotis are usually abundant in forested areas, and are often associated with human settlement. In summer, reproductive females may form nursery colonies containing hundreds, sometimes thousands of individuals in buildings, attics, and other man-made structures. In late summer, Little Brown Myotis may travel hundreds of kilometres to swarm around caves and abandoned mines (Fenton and Barclay 1980). In NS, this species is known to hibernate in several caves or abandoned mine openings (AMOs) (Moseley 2007).

This species has been shown to be seriously affected by White-Nose Syndrome in NS and other parts of its range, and may be at risk of rapid extirpation in the Northeast US within 20 years, due to White-Nose Syndrome mortality (Frick *et al.* 2010). Due to this threat, the Little Brown Myotis was recently listed as Endangered under the NSESA (NSESA 2013). The Little Brown Myotis was also one of three bat species recently listed as Endangered in Canada by COSEWIC, under a rare emergency listing spurred on by the White-Nose Syndrome issue (COSEWIC 2012a), and has subsequently been listed as Endangered under SARA (SARA 2014).

The Project site provides much forested and wetland area which may be used as roosting and foraging habitat by Little Brown Myotis. The town of Canso, located 12 km to the east of the site, reportedly supports a large concentration of bats (Nova Scotia Bat Conservation 2014). However, a search of the Nova Scotia Abandoned Mine Openings (AMOs) database NSDNR 2014b revealed no unfilled openings within at least 33 km of the site, and there are no documented caves or mines used by bats within 75 km (Moseley 2007). There is no known hibernating or swarming caves in the vicinity of the Black Point site.

Northern Long-eared Myotis

The Northern Long-eared Myotis, also known as the Northern Myotis, is a small non-migratory forest-interior species of bat (Broders *et al.* 2006; Caceres and Barclay 2000; Henderson and Broders 2008; Sasse and Pekins 1996; Jung *et al.* 1999) which feeds on insects and occurs in both hardwood and softwood forests (Foster and Kurta 1999). Northern Long-eared Myotis are known to forage under the forest canopy (Laval *et al.* 1977; Broders *et al.* 2006) often near vernal pools and forest streams (Brooks and Ford 2005). They roost preferentially in deciduous trees (Sasse and Pekins 1996; Menzel *et al.* 2002; Carter and Feldhamer 2005). This species swarms around mines and caves in the fall, and hibernates in many of these same spaces, although not in large numbers.

Due to the current White-Nose Syndrome epidemic mentioned above, the Northern Long-eared Myotis was recently listed as Endangered under the NSESA (NSESA 2013), and was one of three bat species recently listed as Endangered in Canada by COSEWIC, under a rare emergency listing spurred on by the White-Nose Syndrome issue (COSEWIC 2012b), and has subsequently been listed as Endangered under SARA (SARA 2014).

The Project site provides much forested and wetland area which may be used as roosting and foraging habitat by Northern Long-Eared Myotis. The town of Canso, located 12 km to the east of the site, reportedly supports a large concentration of bats (Nova Scotia Bat Conservation 2014). However, a search of the Nova Scotia Abandoned Mine Openings (AMOs) database NSDNR 2014b revealed no unfilled openings within at least 33 km of the site, and there are no documented caves or mines used by bats within 75 km (Moseley 2007). There is no known hibernating or swarming caves in the vicinity of the Black Point site.

6.7.1.4.2 Mammal SOCC Confirmed to Occur on the Black Point Site

To date, a single mammal SAR, Mainland Moose, has been confirmed to occur on the Black Point site.

Mainland Moose

As only very low numbers of Moose occur in Eastern mainland NS, many of the Moose sightings recorded within the 100 km radius in 2010 are likely from the large Cape Breton population, which is an introduced Albertan subspecies (Parker 2003). Only the mainland population of Moose, which is the native Atlantic subspecies, is listed as Endangered by the NSESA, and as 1 (At Risk) by the General Status of Wild Species in Canada for Nova Scotia (2010).

However, mainland moose inhabit second-growth forest, openings, swamps, lakes and wetlands (NatureServe 2013), and suitable Moose habitat occurs within the Project area.

Evidence of moose presence on the Black Point site was observed during wetland surveys conducted by AMEC staff in August 2014. Field surveys targeting mainland Moose were then conducted by AMEC personnel, accompanied by a Mi'kmaq hunter experienced in tracking Moose and other wildlife, in late September 2014. Results are provided in **Appendix N** Attachment F. A winter survey is also planned for early 2015 (comprising two survey events) in order to build upon existing data regarding the use of the Project Area and Adjacent Areas by Moose and a follow-up pellet grouping study is planned for spring, 2015.

6.7.1.5 *Herpetile SOCC*

The term herpetile refers to an artificial grouping which includes both reptiles and amphibians.

6.7.1.5.1 Herpetile Priority Species Potentially Occurring on the Black Point Site

Four species of reptiles at risk are listed by SARA, COSEWIC, NSESA and/or GSWSC in NS. There are currently no species of amphibian at risk listed by SARA, COSEWIC, NSESA and/or GSWSC in NS. Of the four herpetile priority species in NS, only the Wood Turtle and Snapping Turtle (*Chelydra serpentina*) have potential to occur in the Project area, and are included in the Shortlist of Priority Fauna Species (**Appendix N** Attachment E). The other two species, Blanding's Turtle (*Emydoidea blandingii*) and Northern Ribbonsnake (*Thamnophis sauritus septentrionalis*), are restricted to southwestern NS, in the general area of Kejimikujik National Park in Queens and Lunenburg Counties (Gilhen 1984) and are not expected to occur on the Project site.

NSMNH (2014) does not list any terrestrial reptile or amphibian species of concern as occurring with the general area of the Project site, though it does state that marine turtles may occur in nearby marine environments. Marine turtle SAR are discussed further in Section 6.7.3.3.

The two species potentially occurring on the site are discussed below.

Wood Turtle

According to data provided by ACCDC in 2010 the Wood Turtle (COSEWIC and SARA Threatened, NSESA Threatened, GSWSC-NS 3 (Sensitive) has been recorded within 100 km of the Project area (**Appendix N** Attachment B). The largest known wood turtle population in NS occurs in the St. Mary's River (MacGregor and Elderkin 2003), which is approximately 70 km west of the Project area. For most of the year, Wood Turtles live along permanent streams, but in summer months they roam widely over a large variety of terrestrial habitats adjacent to streams, including deciduous forest, fields, woodland bogs and marshy pastures. For nesting, Wood Turtles require fairly moist but well-drained, unshaded, vegetation-free sites with loose substrate, such as sandy or gravelly stream banks or sand-gravel bars in streams (MacGregor and Elderkin 2003, NatureServe 2013). They also use such banks for basking and will utilize clearings created by humans for basking or breeding (NatureServe 2013). They prefer hard-bottomed streams and rivers composed of sand or gravel, and avoid streams with clay or mucky substrate; clear rivers and streams of medium size (between 2 m and 30 m wide) are considered ideal (MacGregor and Elderkin 2003).

All the streams on the Project site are very small, almost ephemeral, and their banks are vegetated, and therefore do not meet the species' nesting habitat requirements. Wood Turtles are not likely to overwinter in the very small, shallow streams in the Project area. Although

there is potential foraging habitat during summer months, Wood Turtles are highly unlikely to nest within the proposed site.

Snapping Turtle

According to data provided by ACCDC (2010), snapping turtles (SARA and COSEWIC Special Concern, NSESA Vulnerable, GSWSC= 4 (Secure)) have not been recorded within 100 km of the Project area (**Appendix N** Attachment B). However, Guysborough County is known to be poorly surveyed for many fauna groups, and the lack of snapping turtle reports could be due to a lack of reporting, rather than an actual lack of this species' presence in the region. MacAlpine (2010) states that it is unclear whether snapping turtles inhabit the Atlantic Coast zone in which the Black Point Project site is located. It is reported to occur in the two neighbouring ecozones, the South Central Nova Scotia Uplands and the Nova Scotia Highlands. It is included in this report as a precaution.

Snapping Turtles utilize a wide variety of aquatic habitats, preferring those with a soft muddy or sandy bottom. They are highly aquatic, seldom emerging from the water even to bask, and they are able to tolerate brackish water. Nest sites are often far from water, and may include banks, lawns, gardens, road embankments, or even Muskrat burrows. Snapping Turtles are omnivorous, feeding on invertebrates and plants as well as fish, frogs, and other small vertebrates. They hibernate on the bottom of lakes and rivers. Foraging habitat is marginal for Snapping Turtles on the Project site, though suitable nesting habitat may occur.

Herpetile (reptile and amphibian) surveys were conducted simultaneously with surveys for other taxonomic groups and wetlands on the site throughout the 2010 field season. No evidence of any herpetile SOCC was observed.

No reptile or amphibian SOCC has been confirmed to occur on the Black Point site.

6.7.1.6 *Invertebrate SOCC - Odonates and Lepidopterans*

This section discusses Odonates (dragonflies and damselflies) and Lepidopterans (Butterflies).

The Odonata, or dragonflies and damselflies, are large predatory insects which complete their larval development in aquatic environments before emerging as flying adults. All rely on aquatic habitats for reproduction, and some have very specific habitat requirements. Currently, there are 26 species of odonates listed as 1 (At Risk), 2 (May Be At Risk), or 3 (Sensitive), in the Canadian General Status of Wild Species list for NS. No odonate species are listed under SARA, COSEWIC or the NSESA. The distribution of odonates in NS has not received much study until the last few decades, and Guysborough County is the least studied county in NS (P. Brunelle, pers. comm. 2010). As there are very few odonate experts in eastern Canada, odonate distribution and populations within the province are not as well documented as for other more-easily identified groups.

6.7.1.6.1 Invertebrate Priority Species Potentially occurring on the Black Point Site

Odonates

A review of the known geographic distributions of these species indicates that 23 species of Odonata of conservation concern have potential to occur in eastern NS, and so are included in

the Shortlist of Priority Fauna Species (**Appendix N** Attachment E). Of these, 20 are considered to have potential to occur on the Project site, based on known habitat preferences. These are outlined in Table 6.7.8.

**Table 6.7-8:
Odonate Priority Species with Potential to Occur on the Site**

	Scientific Name	Common Name	GSWSC-NS ¹	Habitat ²
1	<i>Boyeria grafiana</i>	Ocellated Darner	3- Sensitive	Lotic obligate; found near rapid forest streams and lakes with rocky substrate. Flight period: early June to late September.
2	<i>Coenagrion interrogatum</i>	Subarctic Bluet	2- May Be At Risk	Peatland obligate. Found in open marshes and bogs with cool water, abundant aquatic mosses. Flight period: early June to early August
3	<i>Coenagrion resolutum</i>	Taiga Bluet	2- May Be At Risk	Ponds, marshes, sphagnum pools. Flight period: late May to late July.
4	<i>Enallagma signatum</i>	Orange Bluet	2- May Be At Risk	Lentic habitats, including ponds and lakes. Flight period: late June to early September.
5	<i>Enallagma vesperum</i>	Vesper Bluet	3- Sensitive	Lentic habitat; found in small lakes with lots of floating vegetation and occasionally slow-moving streams.. Flight period: early July to mid August.
6	<i>Gomphaeschna furcillata</i>	Harlequin Darner	3- Sensitive	Found in bogs and swamps, including alder swamps. Flight period: mid May to late July.
7	<i>Gomphus desertus</i>	Harpoon Clubtail	3- Sensitive	Breeds in clear, rapid rocky streams with sandy or silty bottoms. Feeds in clearings and along forest edges. Flight period: early June to mid July.
8	<i>Leucorrhinia patricia</i>	Canada Whiteface	2- May Be At Risk	Peatland obligate. Found in bogs, fens, and lakes with mats of floating moss or shallow pools. Flight period: early June to mid July.
9	<i>Pantala hymenaea</i>	Spot-winged Glider	3- Sensitive	Peatland obligate; found in fresh and brackish temporary pools and ponds. Flight period: late June to mid August.
10	<i>Somatochlora brevicincta</i>	Quebec Emerald	2- May Be At Risk	Peatland obligate; found in grassy bogs, poor fens and acid fens. Flight period: late June to mid September.
11	<i>Somatochlora forcipata</i>	Forcinate Emerald	2- May Be At Risk	Lentic habitat; found in small spring-fed streams and alder swamps. Flight period: early June to mid August.
12	<i>Somatochlora franklini</i>	Delicate Emerald	3- Sensitive	Peatland obligate; found in shallow, mossy bogs and fens with short sedges or horsetails. Flight period: early June to early August.
13	<i>Somatochlora</i>	Kennedy's Emerald	2- May Be At Risk	Slow open streams in wetlands, boreal swamps, and

	Scientific Name	Common Name	GSWSC-NS ¹	Habitat ²
	<i>kennedyi</i>			cool, shady bog ponds. Feeds over roads and streams. Flight period: late May to early September.
14	<i>Somatochlora williamsoni</i>	Williamson's Emerald	2- May Be At Risk	Slow streams and lakes including bog lakes, usually with clear water. Flight period: mid June to mid September.
15	<i>Ophiogomphus mainensis</i>	Maine Snaketail	2- May Be At Risk	Feeds in fields, and breeds in clear, moderately rapid rocky forest streams, often draining lakes or swamps. Flight period: late May to early August.
16	<i>Ophiogomphus aspersus</i>	Brook Snaketail	2- May Be At Risk	Feeds in fields and along forest trails, and near water. Breeds in clear open streams with brushy banks and sand, gravel or rock riffles. Flight period: early June to early September.
17	<i>Stylurus scudderii</i>	Zebra Clubtail	2- May Be At Risk	Clear forest streams, small rivers. Forages along forest edges and in clearings. Flight period: late June to early October.
18	<i>Sympetrum danae</i>	Black Meadowhawk	3- Sensitive	Bogs, fens and marshes; occasionally saline or moving water. Flight period: late July to late October
19	<i>Tramea lacerata</i>	Black Saddlebags	2- May Be At Risk	Ponds (including temporary ponds), lakes and ditches without fish. Flight period: mid May to mid October.
20	<i>Williamsonia fletcheri</i>	Ebony Boghaunter	2- May Be At Risk	Bog pools and forest fens. Flight period: late May to early July.

1= General Status of Wild Species in Canada- Nova Scotia rank; 2= Sources are Dunkle (2000) and BugGuide (2014)

See Section 6.4.3.3 for a description of the odonate surveys conducted on the Project site in 2010; odonate surveys were conducted by Mr. Paul Brunelle, a well-known expert of Odonata of the Maritimes. He conducted his initial surveys in June and July of 2010, and AMEC staff collected additional specimens in August and September of 2010, in order to accurately characterize the odonate fauna of the site. Mr. Brunelle's report is provided in Section 6.4- **Appendix E**.

According to ACCDC (2010), six odonate priority species have been reported within a 100 km radius around the Project area (Appendix N2). These were Williamson's Emerald, Maine Snaketail, Brook Snaketail, Black Meadowhawk, Harlequin Darner, and Ocellated Darner. No odonates were listed within five km of Black Point in the 2014 ACCDC report (**Appendix N Attachment C**).

The NSMNH does not have any records of odonate species of concern in the general Project area (**Appendix N Attachment D**), and no Significant Habitat areas for odonates are listed by NSDNR within 20 km of the Project site (NSDNR 2012).

The Project area contains several types of aquatic habitats which are potential breeding sites for odonates such as streams, bogs, ponds, and marshes. Based on habitat requirements

(Appendix N Attachment E), potential breeding habitat exists for most odonate priority species on the short-list.

Lepidopterans

Ten butterfly and moth species are listed as SAR or SOCC in NS by SARA, COSEWIC, NSESA, and/or the General Status of Wild Species in Canada, and are known to occur in NS. Of these, nine are considered to have potential to occur on the Project site based on known habitat preferences (Appendix N Attachment E). These are listed in Table 6.7.9.

**Table 6.7-9:
Lepidopteran Priority Species with Potential to Occur on the Site**

	Scientific Name	Common Name	GSWSC-NS Status	Habitat ¹
1	<i>Boloria chariclea</i>	Arctic Fritillary	3- Sensitive	Boreal forest clearings and transmission lines; bogs and boggy trails. Frequently visits flowers including daisies and spreading dogbane. Host plant: Various willows; possibly violets.
2	<i>Callophrys lanoraieensis</i>	Bog Elfin	2- May Be At Risk	Bogs, wood roads and sandy pine forests with black spruce. Host plant: Black spruce.
3	<i>Danaus plexippus</i>	Monarch	3- Sensitive	Found in a variety of open habitats; in late summer, congregates in coastal areas to feed on thistle and prepare for migration to Mexico. Host plant: Swamp milkweed and Kansas milkweed.
4	<i>Oeneis jutta</i>	Jutta Arctic	2- May Be At Risk	Colonial, found in bogs and fens. Host plant: Various sedges, including <i>Carex</i> spp. and tussock cotton-grass.
5	<i>Papilio brevicauda</i>	Short-tailed Swallowtail	3- Sensitive	Found on coastal marshes, dunes and headlands. Usually seen within 100 m of the ocean. Host plant: Scotch lovage and other members of the Carrot family.
6	<i>Pieris oleracea</i>	Mustard White	3- Sensitive	Along roadsides and in open spaces in forested areas. Host plant: Various members of the Mustard family, particularly rock cresses and toothworts.
7	<i>Polygonia gracilis</i>	Hoary Comma	3- Sensitive	Often seen visiting flowers (such as Pearly Everlasting), unlike most Commas. Host plant: Various currants (<i>Ribes</i> spp.)
8	<i>Polygonia satyrus</i>	Satyr Comma	3- Sensitive	Woodland species often seen sitting on roads and trails; like most Commas, attracted to animal droppings, carrion, sap and fermented fruit. Host plant: Stinging nettle.
9	<i>Thorybes pylades</i>	Northern Cloudywing	3- Sensitive	Inhabits a variety of open forest and meadow habitats. Host plants: Various legumes, including vetch and beach pea.

¹= Source= Maritime Butterfly Atlas 2014

Three of these priority species have known occurrences within 100 km of the Project area (**Appendix N** Attachment B): Monarch, Short-tailed Swallowtail, and Hoary Comma. No lepidopteran SOCC were listed within five km of Black Point in the 2014 ACCDC report (**Appendix N** Attachment C), and none were observed during the field surveys conducted at the Site. To date, no butterfly Priority Species have been reported to the Maritimes Butterfly Atlas in the 10 km by 10 km atlas square in which the Project area is situated or in any of the adjacent atlas squares (Maritimes Butterfly Atlas 2014).

According to the Maritimes Butterfly Atlas, Hoary Comma has only been reported in northern NB, and the only NS sighting of Short-tailed Swallowtail was at St. Paul Island, off the northern tip of Cape Breton (Maritimes Butterfly Atlas 2014). Jutta Arctic, which had not been recorded in mainland NS prior to initiation of the ongoing Maritimes Butterfly Atlas, has since been reported in Guysborough County (Maritimes Butterfly Atlas 2014). Monarch, Northern Cloudywing and Mustard White have also been recorded in Guysborough County (Maritimes Butterfly Atlas 2014). Based on known distributions and habitat preferences, Monarch, Northern Cloudywing, Mustard White and Jutta Arctic have been retained in the short list of priority species (**Appendix N** Attachment E).

A review of habitat requirements for the butterfly species includes the consideration of larval food-plants. Butterflies depend on plants as a food source for the juvenile stage, the caterpillar. Many species are very specialized on one or a few plant species. Adults are mobile and are expected to be able to search for nectar producing plants in larger, though somewhat limited areas, thus avoiding areas unsuitable due to Project activities. However, presence or absence of larval food-plants ultimately determines the potential for presence of these species in the Project area, as well as the possibility of negative impacts caused by Project activities.

During the breeding season, Monarch butterflies (SARA and COSEWIC: Special Concern; GSWSC-NS = 3 Sensitive) utilize habitats such as meadows, weedy fields and watercourses, where milkweed, the larval food plant, is present. Monarchs can occur almost anywhere in NS during spring migration, and in the breeding season near the food plants. Monarchs are common to abundant during the fall migration, particularly along the Atlantic coast; however, most of these fall migrants are thought to originate from outside the province. Small numbers are resident. During the field surveys, no milkweed plants were found. Therefore, breeding Monarchs are unlikely to be present on the Project site.

Jutta Arctic, though relatively widespread in New Brunswick is uncommon in NS (GSWSC-NS = 2 May Be At Risk). This species is typically observed around margins of bogs and fens. Host plants include a variety of sedges, including *Carex* spp. and Tussock Cotton Grass. As suitable habitat and host plants occur in the Project area, breeding Jutta Arctic may be present.

Northern Cloudywing (GSWSC-NS = 3 Sensitive) utilizes a variety of open forest and meadow habitats where it is frequently observed visiting flowers. This species is highly colonial, and may be locally common. All but one of the Atlas records for the province all are from Guysborough and Antigonish Counties. Suitable habitat exists and at least one of the host plant species, Beach Pea, has been found in the Project area; therefore, it is possible that Northern Cloudywing may breed in the Project area, although none were observed during field surveys.

Mustard White (GSWSC-NS=3 Sensitive) is found in forest openings and along roadsides, and utilizes a variety of members of the mustard family (Brassicaceae), such as rock cresses and toothworts, as its host plants. The species is uncommon but widespread in the Maritimes. Suitable habitat for the Mustard White is present in the Project area, and so it is considered to possibly breed there, although none were observed during field surveys on the Site.

6.7.1.6.2 Invertebrate SOCC Confirmed to Occur on the Black Point Site

Only one priority species of invertebrate has been detected on the site to date, the Spot-winged Glider (*Pantala hymenaea*).

The spot-winged glider is a large dragonfly species which is migratory in north-eastern North America (Paul Brunelle, pers. comm. 2010). It is listed as 3 (Sensitive) by GSWSC-NS, meaning it is not believed to be at risk of immediate extirpation or extinction within the province but may require special attention or protection to prevent it from becoming at risk. A specimen was observed near shallow bog pools in Wetland 11, engaging in mating behaviour. However, it is not known if such bog pools are suitable for larval development of the fast-growing larvae of this genus (Paul Brunelle, pers. Comm. 2010.) See the Odonate report in Section 6.4, **Appendix E** for further details.

No SOCC butterfly species have been detected on the Black Point site to date.

6.7.2 Freshwater SAR and SOCC

6.7.2.1 *Freshwater Fish SAR and SOCC*

A total of 10 species, representing 17 populations of freshwater and/or anadromous fish species are listed as SAR/SOCC by NSESA, SARA, COSEWIC, and GSWSC-NS. Note that different populations of a species are often treated separately due to differing environments and threats, a good example being the various Salmon populations in NS.

Fish species which spend portions of their life histories in both fresh and salt water will be discussed in both of these sections, and impacts to either one of these environments can have impacts on these species.

6.7.2.1.1 Freshwater Fish SOCC Potentially Occurring on the Black Point Site

A review of the known geographic distributions of these freshwater fish species and populations of concern in NS indicates that nine species of freshwater, anadromous, or catadromous fish species of conservation concern have potential to occur in eastern NS, and so are included in the Short-list of Priority Fauna Species (**Appendix N** Attachment E). These are listed in Table 6.7.10.

**Table 6.7-10:
Freshwater Fish SOCC and their Potential to Occur on the Site**

Scientific Name	Common Name	GSWSC-NS Status	COSEWIC/ SARA Status	Potential in Region	Potential in Freshwater Habitats on Project Site
<i>Salmo salar</i>	Atlantic Salmon (NS Southern Upland Population)	2-May Be At Risk	Endangered /No status	YES	Unlikely*
<i>Acipenser oxyrinchus</i>	Atlantic Sturgeon	2-May Be At Risk	Threatened /No status	YES	Unlikely*
<i>Alosa pseudoharengus</i>	Gaspereau (Alewife)	3-Sensitive		YES	Unlikely*
<i>Salvelinus fontinalis</i>	Brook Trout (Char)	3-Sensitive		YES	Unlikely
<i>Margariscus margarita</i>	Pearl Dace	3-Sensitive		YES	Unlikely
<i>Culaea inconstans</i>	Brook Stickleback	3-Sensitive		YES	Unlikely
<i>Anguilla rostrata</i>	American Eel	2-May Be At Risk	Threatened /No status	YES	Unlikely*
<i>Morone saxatilis</i> - Southern Gulf of St. Lawrence population	Striped Bass	1-At Risk	Special Concern/No Status	YES	Unlikely*
<i>Salvelinus namaycush</i>	Lake Trout	3-Sensitive		YES	Unlikely

Note:

*See discussion in Marine Fish SAR section

None of these species are expected to utilize any of the freshwater habitats on the Project site. While one small lake (Foghertys Lake) and three small unnamed watercourses are present, none of these are considered suitable fish habitat, as the pH is very low (<3). Gillnetting and electrofishing surveys conducted on the site in 2010 found no evidence of any fish species. No suitable habitat for any of the freshwater fish SOCC occurs on the Project site.

6.7.2.2 Freshwater Invertebrate SOCC

Freshwater invertebrates assessed for this document include the freshwater mussels. Currently, six species of freshwater mussels are considered to be SAR or SOCC in Nova Scotia by SARA, COSEWIC, NSESA, and/or GSWSC for Nova Scotia.

6.7.2.2.1 Freshwater Mussel SOCC Potentially Occurring on the Black Point Site

Six species of freshwater mussel SOCC occur in Nova Scotia. Five of these six Priority species are included in the Shortlist of Priority Fauna Species based on known occurrences (**Appendix N** Attachment E) and are listed in Table 6.7.11. The sixth species, the Yellow Lampmussel

(*Lampsilis cariosa*), occurs in only a single NS location, the Sydney River system on Cape Breton Island. Therefore, this species is not expected to be present within the Project area, and is not included in the habitat evaluation.

**Table 6.7-11:
Freshwater Mussel SOCC Occurring in Nova Scotia**

	Common Name	Scientific Name	SARA Status & Schedule	NSESA	COSEWIC Status	GSWSC-NS
1	Creeper	<i>Strophitus undulatus</i>				2- May Be At Risk
2	Delicate Lampmussel (Tidewater Mucket)	<i>Leptodea ochracea</i> (formerly <i>Lampsilis ochracea</i>)				3- Sensitive
3	Yellow Lampmussel	<i>Lampsilis cariosa</i>	Special Concern / Schedule 1	Threatened	Special Concern	2- May Be At Risk
4	Brook (Swollen Mussel)	Floater Wedge <i>Alasmidonta varicosa</i>	Special Concern / Schedule 1	Threatened	Special Concern	3- Sensitive
5	Eastern Lampmussel	<i>Lampsilis radiata</i>				3- Sensitive
6	Eastern Pearlshell	<i>Margaritifera margaritifera</i>				3- Sensitive

No freshwater mussel SOCC was listed in the 2014 ACCDC database search within a five km radius of the Black Point Site (**Appendix N** Attachment B). The 2010 ACCDC report listed three species of concern within a 100 km radius from the Project area (Triangle Floater *Alismadonta undulata* (4 records); Brook Floater *A. varicosa* (6 records), and Eastern Lampmussel *Lampsilis radiata* (15 records)). None were within a 20 km radius of the proposed Project footprint. Distribution maps show that the Triangle Floater, Brook Floater and Delicate Lamp Mussel have occurrences in Guysborough County (Clarke 1981). In addition to these three species, Martel *et al.* (2010), in their summary of the known distributions of freshwater mussel species within Atlantic Maritime Ecozone, state that an additional freshwater mussel SOCC, the Eastern Pearlshell *Margaritifera margaritifera*, also occurs in the drainage system encompassing the Black Point site.

None of these species are expected to occur on the Black Point site, as the water in the aquatic habitats present is too acidic to support fish, which several of these species depend upon as hosts in the larval stage. Some studies have also shown dissolution of the shell periostracum layer in freshwater mussels at pH levels below 3.9 (Mäkelä and Oikari 1992).

No freshwater mussel shells were noted during field surveys in 2010 and 2014 by AMEC staff.

6.7.3 Marine SAR and SOCC

A review of the COSEWIC database, the SARA public Registry listings, and the Canada General Status of Wild Species for NS and the Atlantic Ocean found a total of 39 marine SAR or SOCC (29 fish, 7 mammals, 2 reptiles, 1 mollusc) which are known to occur in the northwestern Atlantic Ocean around Nova Scotia (**Appendix E**; **Appendix N**, Attachment E). This includes species that are fully marine, such as whales, as well as species which rely on marine habitats for only a portion of their life cycle, such as anadromous fishes. Note that marine birds are not included within this section, see Section 6.7.1.3 for a discussion of coastal and seabird species. The habitat preferences of the listed marine SOCC were compared with the known habitats occurring within the planned Black Point footprint to determine the likelihood of their occurrence. Of the 39 SAR or SOCC occurring in this region, 17 are known to occur or have potential to occur within the area encompassing the Project site. These species are discussed in detail in the following subsections.

The single marine mollusc SOCC, the Atlantic Mud-piddock (*Barnea truncata*, COSEWIC Threatened), is a sedentary boring species which occurs only within a specific geological formation in the Minas Basin (COSEWIC 2009a). It is not expected to occur in eastern mainland Nova Scotia, and so is not discussed further in this document.

Note that there is little information available on marine species' distribution in some cases.

6.7.3.1 Marine Fish SOCC

A review of the COSEWIC database and the SARA Public Registry listings for NS and the Atlantic Ocean found a total of 29 marine or diadromous fish SOCC which occur in the northwestern Atlantic Ocean (full list provided in **Appendix N** Attachment E). Distribution ranges and habitat preferences of these species were compared to the site location and the habitat types known to occur off the Black Point site to determine species with potential to occur in the waters at and near the Project site. The species considered to have potential to occur in the region are outlined in Table 6.7.12. Note that a few species occur in both freshwater and marine environments, and so, for the sake of completeness, are discussed in both the Freshwater and Marine SAR sections.

6.7.3.1.1 Marine Fish SOCC Potentially Occurring on the Black Point Site

A total of 15 marine fish SAR or SOCC which utilize marine habitats are deemed to have potential to occur in the waters at and near the Project site. A brief description of the habitat and life history of each of these fish species, along with its current designation under COSEWIC and/or SARA is provided below in Table 6.7.12.

**Table 6.7-12:
Marine Fish SOCC with the Potential to Occur at/near the Site**

	SCIENTIFIC NAME	COMMON NAME	STATUS LISTS	POSSIBLE OCCURRENCE IN HABITATS AT/NEAR SITE
1	<i>Acipenser oxyrinchus</i>	Atlantic Sturgeon	COSEWIC= Threatened GSWSC- NS=2 (May Be At Risk)	Possible
2	<i>Anguilla rostrata</i>	American Eel	COSEWIC= Threatened GSWSC- NS=2 (May Be At Risk)	YES
3	<i>Gadus morhua</i>	Atlantic Cod-Southern population	COSEWIC =Endangered, GSWSC- NS=3 (Sensitive)	YES
4	<i>Hippoglossoides platessoides</i>	American Plaice- Maritimes population	COSEWIC= Threatened GSWSC- NS=2 (May Be At Risk)	YES
5	<i>Hippoglossus hippoglossus</i>	Atlantic Halibut	GSWSC-NS=2 (May Be At Risk)	YES
6	<i>Lamna nasus</i>	Porbeagle	COSEWIC= Endangered GSWSC- NS= 1(At Risk)	Possible
7	<i>Leucoraja ocellata</i>	Winter Skate - Eastern Scotian Shelf population	COSEWIC= Threatened GSWSC- NS= 3 (Sensitive)	Possible
8	<i>Pollachius virens</i>	Pollock	GSWSC-NS= 3 (Sensitive)	YES
9	<i>Salmo salar</i>	Atlantic Salmon - NS Southern Upland Population	COSEWIC= Endangered GSWSC- NS= 1 (At Risk)	YES
10	<i>Squalus acanthias</i>	Spiny Dogfish	COSEWIC= Special Concern GSWSC-NS= 3 (Sensitive)	Possible
11	<i>Thunnus alalunga</i>	Albacore	GSWSC-NS= 3 (Sensitive)	Possible
12	<i>Thunnus albacares</i>	Yellowfin Tuna	GSWSC-NS= 3 (Sensitive)	Possible
13	<i>Thunnus obesus</i>	Bigeye Tuna	GSWSC-NS= 3 (Sensitive)	Possible
14	<i>Thunnus thynnus</i>	Atlantic Bluefin Tuna	COSEWIC= Endangered, GSWSC-NS= 2 (May Be At Risk)	Likely - Fished Nearby
15	<i>Urophycis tenuis</i>	White Hake-Atlantic and Northern Gulf of St. Lawrence population	COSEWIC= Threatened GSWSC- NS= 2 (May Be At Risk)	Possible

Each of these species is discussed briefly in the following paragraphs.

Atlantic Sturgeon

Atlantic Sturgeon are large, slow-growing armoured fish which live and mature in the sea, but spawn in freshwater, where some juvenile rearing also occurs. They occur in rivers, estuaries, nearshore marine environments and shelf regions to at least 50 m depth along the Atlantic Coast of North America (COSEWIC 2011a). They are listed as Threatened by COSEWIC and as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Breeding populations are known from the St Lawrence and Saint John Rivers and possible in other rivers flowing into the Bay of Fundy and the Gulf of St Lawrence. Adults spend most of their time at sea, but generally remain close to shore (COSEWIC 2011a).

While Atlantic Sturgeon was not listed in the 2010 ACCDC screening conducted for this Project, reliable sightings of a small group (4-5) of juvenile Atlantic Sturgeon were noted in 2009 within Guysborough County by a qualified AMEC biologist (Cameron-MacMillan, M., pers. comm. 2013). These records have recently been reported to ACCDC. The lake and watercourses on the Project site are unsuitable for Atlantic Sturgeon, but it is possible that adults may occasionally forage in the marine portion of the footprint. No critical habitat is present.

American Eel

The American Eel spawns and hatches in the marine environment, but grows to maturity in freshwater. Adults and early larval stages likely utilize the marine portion of the Project footprint as they migrate to and from streams in Guysborough County. While Eels are still relatively abundant in eastern Canada, population decreases in Ontario and Quebec have led to COSEWIC recently listing the American Eel as a Threatened species (COSEWIC 2012a). It is also listed as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Eels continue to be a significant species to Mi'kmaq people in eastern Canada.

The lake and watercourses on the Project site are unlikely to support American Eel, as they are very acidic, but it is quite likely that adults and early larval stages forage in the marine portion of the Project footprint. No critical habitat is present.

As a catadromous species, American Eel is also discussed in Section 6.7.2.1.1.

Atlantic Cod-Southern Population

The Atlantic Cod is a marine fish species which has historically been extremely important as a commercial species in eastern Canada, but is now at very low levels and only limited fishing is permitted. The Southern population, which encompasses the Project site, is now listed by COSEWIC as Endangered (COSEWIC 2010a) and as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Knowledge of the habitat requirements of Atlantic Cod is rather poor, and it has been suggested that habitat requirements change with age (COSEWIC 2010a). Cod are known to occur in inshore waters along the Guysborough coast, and Atlantic Cod likely forage within the Project footprint, though no habitat critical to this species is present.

American Plaice- Maritimes Population

American Plaice is a species of flounder which burrows in sediments to escape predators and ambush prey. Juvenile American plaice prefer depths of 100 to 200 m, but adults are less particular regarding habitat and could potentially occur within the Project footprint. The Maritime

population was designated as Threatened by COSEWIC in 2009 (COSEWIC 2009b) and as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Abundance of mature individuals has declined about 67% on the Scotian Shelf within the last few generations. It is reasonable to assume that adult American Plaice may occasionally forage within the Project footprint, though no critical habitat is present.

Atlantic Halibut

The Atlantic Halibut is the largest of the flatfishes and can be found in cool boreal and subarctic waters on both sides of the North Atlantic (Scott and Scott 1988). In the summer the Atlantic Halibut inhabits shallow waters and in the winter it moves into deeper waters, preferring temperatures above 2.5 °C. The migratory patterns of the halibut can be strong and may migrate great distances at times however they are not classified as highly migratory. Depending on the Atlantic Halibut's size, the food sources are invertebrates, mainly marine annelid worms and crustaceans, and other fishes. The Atlantic Halibut is ranked as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca).

Porbeagle

The Porbeagle is a large cold-temperate coastal and oceanic shark which tends to be more common on continental shelves, but is occasionally found close inshore (Scott and Scott 1988; Compagno 2001). It feeds on wide variety of species, especially bony fishes and Squid (Joyce *et al.* 2002). Porbeagle abundance has declined greatly since Canada began fishing them in the 1990s. This species was listed by COSEWIC as Endangered in 2014 (COSEWIC 2004) and is listed as 1 (At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). It is possible that Porbeagles may occasionally forage within the waters at or near the Project site. No critical habitat is present.

Winter Skate

Winter Skate (*Leucoraja ocellata*) is a bottom-dwelling skate species, which is usually found on sand and gravel. The Project site falls within the region home to the Eastern Scotian Shelf population of this species, which is subject to a small directed fishery. Very little is known about the biology of Winter Skate; however, this species' delayed age at maturity, large size at birth, long generation time, low fecundity, and consequently slow population growth rate have led to COSEWIC listing this species as Threatened (COSEWIC 2005) and as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Winter Skate are also at risk of bycatch in fisheries for other groundfish species and/or scallops. Habitat within the marine footprint of the Project is likely marginal foraging habitat for winter skate. No critical habitat is present.

Pollock

Pollock occur on both sides of the North Atlantic and inhabit a broad depth range from 37 to 364 m, with a preferred depth of 110 to 181 m. Juvenile Pollock move inshore in summer and offshore in winter while adult Pollock are more commonly found in deeper water near shore, or on offshore banks. Pollock can endure temperatures as low as zero degrees Celsius but are more commonly found in higher temperatures, although not above 15.5 to 18.3 ° C. Pollock feed on crustaceans and fish in mainly equal proportions, however larger Pollock tend to eat more fish than smaller Pollock (Scott and Scott 1988). Pollock is ranked as 3 (Sensitive) on the

GSWSC list for the Atlantic Ocean (www.wildspecies.ca). It is possible that juvenile Pollock may occur within the Project's marine footprint in summer.

Atlantic Salmon

Atlantic salmon prefer rivers or streams that are generally clear, cool and well-oxygenated for reproduction and the first few years of rearing, but undertakes lengthy feeding migrations in the North Atlantic Ocean as older juveniles and adults. The Southern NS Upland population, which encompasses the Black Point site, breeds in rivers from north-eastern mainland Nova Scotia, along the Atlantic coast and into the Bay of Fundy. Atlantic Salmon have historically supported important fisheries in eastern Canada; however, most populations are now listed as Endangered by COSEWIC (2010b) and as 1 (At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). The number of mature individuals has declined over the past few generations by about 61%. In addition, recent surveys have only found juvenile Salmon in 20 of 51 known historic spawning rivers in NS (COSEWIC 2010b). Human influences, such as dam construction, pollution and logging, have eliminated and/or degraded freshwater spawning and foraging habitats. Acidification of freshwater habitats brought about by acidic precipitation is another ongoing threat to this species' survival.

It is likely that adult Atlantic Salmon may occasionally forage within the marine portion of the Project footprint, though no critical habitat is present.

As an anadromous species, Atlantic Salmon is also discussed in Section 6.7.2.1.1.

Spiny Dogfish

The Spiny Dogfish (*Squalus acanthias*) is a small shark which occurs world-wide on the continental shelf, from the intertidal to the shelf slope, in temperate and boreal waters. While still relatively abundant in Canadian waters, this species' low fecundity, long generation time, and vulnerability to overfishing in nearby US waters, have led to it being listed as a species of Special Concern by COSEWIC (2010c) and as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Habitat within the marine footprint of the Project is likely suitable foraging habitat for Spiny Dogfish. No critical habitat is present.

Albacore Tuna

Albacore is a deep swimming tuna species which occurs worldwide in tropical and temperate seas. It can withstand temperatures as low as 9.5 °C but prefers between 13.5 and 25.2 °C (Scott and Scott 1988). They do not breed in Canadian waters. Albacore is ranked as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Albacore can occur off NS during the late summer and fall months, and could potentially occur within the marine footprint of the Project site.

Yellowfin Tuna

Yellowfin Tuna is a slender, large fish which can be found in the Atlantic, Pacific, and Indian oceans. It prefers warmer temperatures, ranging from 18 to 31° C. The Yellowfin Tuna occurs along the continental shelf off Nova Scotia southward, into the Caribbean Sea and Gulf of Mexico, to southern Brazil (Scott and Scott 1988). They do not breed in Canadian waters. Yellowfin Tuna is ranked as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca) and can occur off NS during the late summer and fall months. Yellow

Tuna could potentially occur within the marine footprint of the Project site but none have been reported.

Bigeye Tuna

Bigeye Tuna occur worldwide, from Portugal to South Africa in the eastern Atlantic, and from off the Scotian Shelf to northern Brazil in the western Atlantic. This species occur in more temperate waters, ranging from 7.8 to 18.4 degrees Celsius (Scott and Scott 1988). Bigeye Tuna is ranked as 3 (Sensitive) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca) and can occur off NS during the late summer and fall months. Bigeye Tuna could potentially occur within the marine footprint of the Project site but none have been reported.

Atlantic Bluefin Tuna

Atlantic Bluefin Tuna is a large predatory fish species which spawns in the Gulf of Mexico. Adults and large juveniles move northward to forage on smaller schooling fish species in warm Canadian waters in the summer and fall (COSEWIC 2011b). They are ranked as Endangered by COSEWIC and as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). Despite large population decreases, Atlantic Bluefin Tuna are still fished commercially off Guysborough County (see Section 6.11), and it is likely that adults may forage within the waters at or near the Project site, though no critical habitat is present.

White Hake-Atlantic and Northern Gulf of St. Lawrence population

The White Hake occurs in cold water over deep mud bottom on the continental shelf and upper continental slope. In Canadian waters it occurs from southern Labrador into the Strait of Belle Isle and throughout the Gulf of St Lawrence, around Newfoundland, Scotia Shelf, Bay of Fundy, Passamaquoddy Bay, and Georges Bank. It can be found in deep parts of the Laurentian and Fundian channels and on the continental slope off Nova Scotia. White Hake are mainly found below 200 m moving progressively into deeper waters. White Hake feed heavily on fish, such as clupeids and gadoids, and less frequently, crustaceans (Scott and Scott 1988). This species was designated as Threatened by COSEWIC in 2013 and as 2 (May Be At Risk) on the GSWSC list for the Atlantic Ocean (www.wildspecies.ca). It is possible that adults may occasionally forage within the Project's marine footprint although no reports of this species have been collected within the Project Area.

6.7.3.2 Marine Mammal SOCC

Marine mammals potentially occurring off NS include whales, dolphins, porpoises and seals. A review of the COSEWIC database, the SARA Public Registry listings for NS, and the Canada General Status of Wild Species lists for the Atlantic Ocean found a total of seven marine mammals SAR or SOCC listed for the marine environment off Nova Scotia.

6.7.3.2.1 Marine Mammal SOCC Potentially Occurring at/near the Black Point Site

The NSMNH Screening states that the marine waters adjacent to the Project site may support resident or migratory species of cetaceans (whales) during the appropriate season. Habitat preferences of the species in Table 6.7.13 were compared to the site location and the habitat types known to occur in the waters at or near the Black Point site to determine species with potential to occur in the area of the Project site. All seven of these marine mammals SOCC are known to occur in the northwestern Atlantic Ocean off eastern Nova Scotia (**Appendix N**

Attachment E). Of these seven, only a single species, the Harbour Porpoise, is considered to have potential to occur in Project site waters. This species is discussed in the following paragraphs.

**Table 6.7-13:
Marine Mammal SOCC with the Potential to Occur in Site Waters**

Common Name Population	Species Name	COSEWIC Status /SARA Status & Schedule/ GSWSC- Atlantic	Potential in Site Waters
Blue Whale Atlantic	<i>Balaenoptera musculus</i>	SARA= Endangered (Schedule 1) COSEWIC = Endangered GCWSC-ATL= 1 (At Risk)	Unlikely
Fin Whale Atlantic	<i>Balaenoptera physalus</i>	SARA = Special Concern (Schedule 1) COSEWIC = Special Concern GCWSC-ATL = 3 (Sensitive)	Unlikely
Harbour Porpoise Northwest Atlantic	<i>Phocoena phocoena</i>	COSEWIC Special Concern GCWSC-ATL = 3 (Sensitive)	Possible
Killer Whale Northwest Atlantic	<i>Orcinus orca</i>	COSEWIC = Special Concern GCWSC-ATL = 3 (Sensitive)	Unlikely
North Atlantic Right Whale	<i>Eubalaena glacialis</i>	SARA = Endangered (Schedule 1) COSEWIC = Endangered	Unlikely
Northern Bottlenose Whale Scotian Shelf	<i>Hyperoodon ampullatus</i>	SARA = Endangered- (Schedule 1) COSEWIC = Endangered GCWSC-ATL = 3 (Sensitive)	Unlikely
Sowerby's Beaked Whale	<i>Mesoplodon bidens</i>	SARA= Special Concern (Schedule 1) COSEWIC = Special Concern GCWSC-ATL = 3 (Sensitive)	Unlikely

Harbour Porpoise

The Harbour Porpoise (*Phocoena phocoena*) is one of the smallest marine mammals, reaching a maximum of about 1.9 m in length and 76 kg. They occur primarily on continental shelves, and eat mostly small schooling fish (such as Herring, Capelin, Sprat, and Silver Hake), but also Squid (Waring *et al.* 2009). They are often spotted in harbours and bays. While currently abundant, this species is considered a species of Special Concern in Canada (COSEWIC 2006) and is listed as 3 (Sensitive) on the CGSWS list for the Atlantic Ocean. The Harbour Porpoise is also protected under the *Marine Mammal Regulations* of the *Fisheries Act*, which prohibits harvest. A major source of mortality for Harbour Porpoises is by-catch from fishing gear (especially gillnets) (COSEWIC 2006).

The marine footprint of the Project contains suitable foraging habitat for Harbour Porpoises, however this is not considered critical habitat.

6.7.3.3 Marine Reptile SOCC

A review of the COSEWIC database, the Species at Risk Public Registry listings, and the CGSWS status listings for NS and the Atlantic Ocean found a total of two marine reptiles SAR or SOCC which are known to occur in the northwestern Atlantic Ocean off eastern NS.

Distribution ranges and habitat preferences of these species were compared to the site location and the habitat types known to occur off Black Point to determine species with potential to occur in the waters at or near the Project site.

6.7.3.3.1 Marine Reptile SOCC Potentially Occurring on the Black Point Site

The NSMNH Screening states that the marine waters adjacent to the site may seasonally support migratory species of sea turtles in the appropriate season (**Appendix N** Attachment D). Only a single species, the Atlantic Leatherback (*Dermochelys coriacea coriacea*), is considered to have potential to occur in Project site waters (**Appendix N** Attachment E). A second marine turtle species, the Atlantic Loggerhead (*Caretta caretta*), is also listed by COSEWIC (2010d) as Endangered, but this species only occurs as juveniles far offshore, and is not expected to occur on or near the Project site.

Atlantic Leatherback

The Atlantic Leatherback (*Dermochelys coriacea coriacea*) is a large, slow-growing, long-lived migratory sea turtle species, which comes ashore only to lay eggs. This species breed in tropical or subtropical waters and moves to temperate waters in search of food (chiefly jellyfish) at other times of the year. While they do not breed in Canada, adult leatherbacks are a regular part of the Nova Scotian marine fauna in the summer and fall (James *et al.* 2006; Witzell 1999). Leatherbacks in Atlantic Canada occur in both offshore and coastal waters. The Atlantic Leatherback Turtle is listed by COSEWIC as Endangered (COSEWIC 2012d). Globally, this species is estimated to have declined by more than 70%. In the Atlantic, this species continues to be impacted by fisheries bycatch, coastal and offshore resource development, marine pollution, poaching of eggs, changes to nesting beaches and climate change (COSEWIC 2012d). Canadian waters provide an important foraging area for these turtles, however, entanglement in longline and fixed fishing gear remains a significant threat to Atlantic Leatherbacks in Canadian waters (COSEWIC 2012d).

It is possible that adult Atlantic Leatherbacks may forage within or near the marine portion of the Project footprint; however, no critical habitat for Atlantic leatherbacks is present.

For an assessment of the interaction between the Project and the herein described environment, refer to Section 7.12.

6.8 Socio-Economic Conditions

6.8.1 Nova Scotia Economic Outlook

The economic growth of Nova Scotia has been slower than the Canadian average (slowest of any province) for the past two decades (1990-2012). Demographic conditions have been the major driver for this slow growth rate: over the same time period, the population of Nova Scotia only grew by 0.2 %/year vs. the national population growth of 1%/year (GNS 2014a).

The economy of Nova Scotia was relatively stable during the global financial crisis (2008-2009). However, growth has been slow in subsequent years. The Gross Domestic Product (GDP) in 2012 declined due to reductions (-18.7%) in investments in machinery and equipment (end of Deep Panuke platform construction), reductions in natural gas production and the forestry sector restructure, which resulted in lowered exports from this sector (GNS 2014a).

Increased natural gas production, a more robust economy in the United States and a lower Canadian dollar value are expected to result in growth in 2014. The Department of Finance and Treasury Board estimates a real GDP growth of 1.4% in 2014 and 1.9 % in 2015 (GNS 2014a).

Nova Scotia's longer term economic outlook will be driven by large projects such as the national shipbuilding procurement strategy, the Maritime Link to Lower Churchill hydroelectric power, wind energy developments, MacDonald Bridge re-decking, offshore energy exploration and the completion of the Halifax Convention Centre (GNS 2014a).

6.8.2 Local Socio-Economic Conditions

6.8.2.1 Social Environment

Population and Demographics

The Project area is located in the Municipality of the District of Guysborough (MODG); approximately 10 km west of Canso, along the south shore of Chedabucto Bay. Since the collapse of the ground fishery in the 1990s, significant changes have occurred in the population of the region. Guysborough County as a whole has the fourth largest proportion of out-migration patterns in Nova Scotia (ACOA 2009). Canso has experienced a dramatic population loss and shift in demographic profile. From 1996 to 2006, its population declined 19%, from 1,127 to 915 compared to a population gain of 0.5% for the Province of Nova Scotia as a whole (Gardner Pinfold 2011). Similarly, the population of MODG decreased by 19% between 2001 and 2011, to a population of 4,990 (Gardner Pinfold 2011).

The age distribution in the MODG indicates an older population with a median age of 53.9, compared to the Province of Nova Scotia of 43.7. In 2011, 15.5% of the population was under the age of 20, and 27.4% of the population was 65 years or older (SC 2011). The age distribution in the MODG indicates an older population with a median age of 53.9, compared to the Province of Nova Scotia of 43.7. In 2011, 15.5% of the population was under the age of 20, and 27.4% of the population was 65 years or older (SC 2011).

In 2011 the population of Canso was 1,326. This is a 21.8% decline from 2001. During this time, 18.1% of the population was under the age of 20 and 22.4% was 65 years or older (GNS 2014b).

The cultural origins of the populations of Guysborough County and Canso in 2011 are presented in Table 6.8-1. The majority of the population of both Guysborough County and Canso are of European origins (60% and 69% respectively). North American and North American Aboriginal were the next highest ethnic origins identified by the populations of Guysborough County and Canso. Note that as part of the National Household Survey, respondents may have identified only a single ethnic origin or multiple ethnicities.

**Table 6.8-1:
Cultural Origins of Guysborough County and Canso in 2011**

Origin	Guysborough County		Canso	
	Number	%	Number	%
European	6110	60%	1026	69%
North American	3080	30%	394	26%
North American Aboriginal	610	6%	36	2%
African	270	3%	12	0.8%
Asian	40	0.4%	20	1.3%
Caribbean	15	0.1%	0	0%
Latin/Central/South American	0	0%	0	0%
Oceania	0	0%	0	0%

Source: GNS 2014b and SLR interpretation

Recreation and Leisure

The nearest recreational facility is the Canso SportsPlex, which houses an arena, pool, and several sports fields. Other outdoor multi-purpose facilities in the MODG are located in Larry's River, Little Dover, Country Harbour, and St. Francis Harbour.

There are several fitness centers located within the MODG that offer a variety of fitness activities and programs: Chedabucto Fitness Centre in Guysborough, The Fanning Fitness Centre in Hazel Hill, and Community Fitness Centres in Isaac's Harbour Medical Centre, Whitehead (at the old Fire Hall), New Harbour Community Centre, and the Queensport Fire Hall (MODG 2014a).

There are two seasonal outdoor heated pools, one is located at the Canso Sportsplex and the other is part of the Chedabucto Family of Schools in Guysborough. Other outdoor recreational activities/facilities include a nine-hole golf course (Osprey Shores Resort) and two lighted outdoor tennis courts in Guysborough and outdoor skating rinks are located in Guysborough, Queensport, Little Dover, Larry's River, and Country Harbour and a curling club in Hazel Hill (MODG 2014a).

Hunting and fishing are popular activities in the MODG with big game hunting of deer and bear and inland and deep sea fishing. The area is popular for fishing blue fin tuna, shrimp, ground fish, scallop, snow crab and Atlantic Mackerel (GCIFA 2014a). Recreational boaters use community wharfs or serviced marina located in Canso and Guysborough, Auld's Cove and Ballantyne's Cove. There is no recreational fishing occurring in any of the freshwater sites located on the Project site. The water does not provide suitable habitat for any fish species

(Section 6.5.2). No recreational ocean fishing is conducted from the Project site as there is no safe access to the ocean due to the cliffs on the northern edge of the property.

Health and Social Services

The Project site is located within the district health authority of Guysborough Antigonish Strait Health Authority (GASHA). Within Guysborough County the GASHA operates two hospitals near the Project site (Table 6.8-2). Both hospitals operate a 24-hour emergency service and a variety of outpatient services.

**Table 6.8-2:
Hospitals Near the Project Site**

Hospital Name	Location	Number of Beds	Services
Eastern Memorial	Canso	8	Diagnostic Imaging, EKG, Emergency Services, Laboratory Services, Mental Health Outpatient Services, Physiotherapy, Social Work Services, Cancer and Supportive Care
Guysborough Memorial	Guysborough	10	Diagnostic Imaging, EKG, Emergency Services, Laboratory Services, Mental Health Outpatient Services, Physiotherapy, Nutrition and Dietetic Counselling, Physiotherapy, Social Work Services

Source: GASHA 2014.

There is a nursing home in Canso (Seaside Manor) and a special care facility in Guysborough (Milford Haven). Social services can be found throughout the MODG and those available near the Project site are presented in the Table 6.8-3.

**Table 6.8-3:
Social Services Located Within the MODG**

Service	Location(s)
Mental Health	Eastern Hospital in Canso and Guysborough Memorial Hospital in Guysborough
Addiction Support	Eastern Hospital in Canso and Guysborough Memorial Hospital in Guysborough
Alzheimer Support	Eastern Hospital in Canso and Guysborough Memorial Hospital in Guysborough

Literacy and Adult Learning	Guysborough
Clothing Bank	Guysborough
Food bank	Half Way Cove, Canso and Guysborough

Sources: GASHA 2014; GALA 2012

There are the churches in Canso and seven in Guysborough, including Baptist, Catholic, and United, with many more throughout the MODG (CCD 2014).

Crime and Public Safety

The Royal Canadian Mounted Police are responsible for policing Guysborough County, with detachments located in Canso, Guysborough and Sherbrooke (RCMP 2014). The 2012 crime statistics for Guysborough County and the province of Nova Scotia are presented in Table 6.8.4.

**Table 6.8-4:
2012 Crime Statistics for Guysborough County and Nova Scotia**

Location	Total # of Crimes	Crime rate/10,000 population	Violent Crimes	Violent Crime/10,000 population	Property Crime	Property Crime/10,000 population	Other Crime	Other Crime/10,000 population
Guysborough County	220	293	54	72	129	172	37	49
Guysborough County Youth	8	174	7	153	1	22	0	0
Nova Scotia	60,042	633	12,954	137	37,307	393	9,781	103
Nova Scotia Youth	5,492	882	1,715	276	2,667	428	1,110	178

Source: GNS 2014b

The crime rate, violent crime, property crime and other crime (per 10,000 people) in Guysborough County is generally half of the corresponding provincial crime rate (per 10,000 people) (Table 6.8-4). Crimes that do occur in Guysborough County are mostly non-violent and are usually related to property crime, which is similar to what is observed on a provincial scale. The crimes committed by the youth of Guysborough County are predominately violent, whereas the type of crime predominately committed by the youth of Nova Scotia is non-violent property crimes (Table 6.8-4).

Community Health

In 2010 the Guysborough County Community Health Board randomly surveyed 370 residents over the age of 15. The survey questions about personal health and well-being were derived from the Canadian Community Health Survey administered by Statistics Canada. The key findings of this survey are summarized in Table 6.8-5, which also includes the results for the Guysborough Antigonish Strait Health Authority (GASHA) region. The GASHA region includes Antigonish County, Guysborough County and the Strait Richmond.

**Table 6.8-5:
2010 Indicators of Community Health for Guysborough County and Canada**

Indicator	Guysborough County	Canada
Physically Inactive	46%	51%
Adult incidence of Over Weight/Obesity*	74%	51%
Consumed Alcohol in past 12 months	73%	NA
Currently Smoking*	22%	23%
Tried Illicit Drugs	37%	NA
Incidence of Cancer	1%	2%*
Incidence of Diabetes	9%	7%
Incidence of Heart Attacks	4%	NA
Incidence of Heart Disease	6%	7%
Incidence of Asthma	12%	9%
Incidence of cataracts or glaucoma	9%	NA
Incidence of Arthritis/Rheumatism	32%	21%
Consider Daily Life Stressful	49%	57%

*Nova Scotia %, as National value not available.

Generally speaking, the people of Guysborough County find daily life less stressful than the average Canadian does. They are less physically active than the rest of Canada, which could be in part why they also have a much higher incidence of overweight/obesity. For several indicators Guysborough County is the same/similar to the rest of Canada (incidence of smoking, cancer, diabetes and heart disease) but has a higher incidence of asthma and arthritis/rheumatism.

6.8.2.2 Infrastructure and Services

Private Residences

The total number of occupied dwellings in Guysborough County in 2011 was 3,685. The majority (84%) of these occupied dwellings were single detached homes. Other types included moveable homes (11%), apartments (3%) and semi-detached/ row/duplex (2%) (GNS 2014b). The total number of occupied dwellings in Canso in 2011 was 593. The breakdown was similar to the County, with the majority (75%) of the occupied dwellings were single detached homes, then moveable homes (15%), apartments (5%) and semi-detached/ row/duplex (4%) (GNS 2014b).

Temporary Housing

A list of bed and breakfasts, motels and campgrounds located in Guysborough County are identified in Table 6.8-6.

**Table 6.8-6:
Temporary Housing in Guysborough County**

Name of Temporary Housing	Location
The DesBarres Manor Country Inn	Guysborough
Foxberry-by-the-Sea Bed and Breakfast and Cottages	Whitehead
Pepperlane Manor	Guysborough
On the Harbour Bed and Breakfast	Isaac's harbour
Seawind Landing Country Inn	Charlos Cove
Last Port Motel	Canso
Lonely Rock Seaside Bungalows	New Harbour
Osprey Shores Golf Resort	Guysborough
Seabreeze Campground and Cottages	Fox Island
Shore To Sea Cottage	Phillips Harbour
Boylston Provincial Park	Boylston
Cape Canso RV Park & Marina	Canso
Salsman Provincial Park	Country Harbour

Source: MODG 2014b

The 2011 average value of dwellings in Canso, Guysborough County and Nova Scotia are presented in Table 6.8-7. (GNS 2014b).

**Table 6.8-7:
Average Value of Dwellings in 2011**

Location	Average Value
Canso	\$94,651
Guysborough County	\$110,604
Nova Scotia	\$201,991

The 2011 average value of dwellings in Canso and Guysborough County were 47% and 55%, (respectively) of the provincial average value of dwellings.

Potable Water, Wastewater and Solid Waste Management

The Project site is currently undeveloped and therefore services such as potable water, wastewater and solid waste management will be addressed during the Project development.

The Town of Guysborough and the community of Canso have municipal water and sewer systems. Little Dover has municipal sewer service and Hazel Hill and the Tickle have municipal water service (MODG 2014a).

The closest solid waste management facility to the Project site is the Guysborough Waste Management facility located in Boylston, approximately 39 km from the Project site (MODG 2014a).

6.8.2.3 Cultural Heritage

Several cultural performance spaces are located in Guysborough: Chedabucto Place Performance Centre, Guysborough Masonic Hall, and the Mulgrave Road Theatre Centre, (MODG 2014a, MRT 2014).

Cultural events that occur proximal to the Project site include:

- Stan Rogers Folk Festival (located within Canso) which usually occurs for several days during the month of July. This festival celebrates Stan Rodgers and his contribution to folk music and East Coast music;
- Queensport Mackerel Derby which occurs late August (<http://www.authenticseacoast.com>); and
- At the Guysborough Marina local fiddlers & step dancers perform every Wednesday evening in August.

6.8.2.4 Economic Environment

Employment and Wages

The 2011 average family income for Canso, Guysborough County and Nova Scotia are presented in Table 6.8-8.

**Table 6.8-8:
Average Family Income in 2011**

Location	Family Income
Canso	\$57,697
Guysborough County	\$62,136
Nova Scotia	\$79,838

Source: (NSb 2014)

The average family incomes in Canso and Guysborough County were 72% and 78% (respectively) of the average family income of Nova Scotia.

Guysborough County has significant challenges to economic development in the region. Guysborough is primarily rural with a relatively low education level, compared to the provincial average. High unemployment levels, combined with high out-migration, dependency on traditional resource sectors, and weak infrastructure are negatively impacting local economic development. Local stakeholders are working to improve economic development on multiple fronts. Projects to develop exportable products, develop aquaculture, improve tourism infrastructure, enhance training opportunities, and a range of other initiatives are continuing (ACOA 2009).

Labour Force and Business Activity

In 2001 Canso's labour participation rate was at 60.5% close to the provincial average of 61%, by 2006 the number of people participating in the job market dropped to 44%, a decline of nearly one-third from 2001 (Gardner Pinfold, 2011) which is indicative of significant out-migration and an aging population.

The overall volatility in employment in Canso from 1996 to 2006 was reflected in notable changes across a number of key industries. The hardest hit sector over the ten-year period was manufacturing, which saw a near total loss of employment (-86%) attributable to the decline and closure of the local fish processing plant, the town's major employer. A number of other sectors experienced major declines in employment over the same period, including transportation and storage (-67%); other services (-63%); and accommodation, food and beverage (-50%) (Gardner Pinfold 2011).

The unemployment rate for May 2014 in the North Shore Economic Region, which includes Guysborough County, was 11.7%, which was higher than the provincial rate of 9.5%. The employment rate for the North Shore Economic Region was 53% which is lower than the provincial rate of 56.7% (SC 2014).

The labour force by industry (%) for Canso, Guysborough County and Nova Scotia is presented in Table 6.8-9.

**Table 6.8-9:
Labour Force (%) by Industry in 2011**

Location	Agriculture/Forestry/Fishing and Hunting	Mining/quarrying and Oil and Gas	Utilities	Construction	Manufacturing	Wholesale Trade	Retail Trade	Transportation and Warehousing	Information and Cultural Industries	Finance and Insurance
Canso	28.9	0	0	9.3	7.5	0	12.5	2.7	0	0
Guysborough County	18	2.1	0.5	10.6	6.7	0.8	9.6	3.7	0.5	1.5
Nova Scotia	3.8	0.8	0.6	6.7	7	3.2	12.6	4	2	3.2

Location	Real Estate, Rental and Leasing	Professional/Scientific and Technical Services	Management of Companies and Enterprises	Administrative and Support/waste	Educational Services	Health Care and Social Assistance	Arts and Entertainment	Accommodation and Food Services	Other Services (except Public Administration)	Public Administration
Canso	0	1.6	0	0	1.3	6.7	0	2.7	0	10.7
Guysborough County	1.3	1.3	1.3	3.5	6.8	11.2	3.6	4.7	4.3	7.8
Nova Scotia	1.4	4.9	0.1	4.9	8	12.3	2	6.5	4.2	9.7

Source: (GNS 2014b).

Although unemployment in the region remains high, in 2011, the majority of working people in Canso and Guysborough County were employed through farming, forestry, fishing or hunting (Table 6.8-9a & 6.8-9b). The majority of the people of Nova Scotia were working retail trade or are in the health care/social assistance industry. Employment through retail trade is also high in Canso, followed closely by public administration. Health care and social services is a common industry of employment for Canso and Guysborough County. The area also has an emerging oil and gas industry, namely the Goldboro Gas Plant, which provides a significant tax base to the region (MODG 2014a).

In 2008, the major employers of Guysborough County were: Ocean Nutrition, St. Mary's River Smokehouses, Liscombe Lodge, Historic Sherbrooke Village, Nova Scotia Government, Local Inshore Fishery and Martin Marietta Materials (IRNS 2008).

The 2011 educational attainment of the population 15 years and older in Canso, Guysborough County and Nova Scotia are presented in Table 6.8-10. (GNS 2014b).

**Table 6.8-10:
Educational Attainment of Population (%) 15 years or older in 2011**

Location	No certificate, diploma or degree	High School	Post Secondary
Canso	50.6	20.3	29.9
Guysborough County	39.3	17.7	43.2
Nova Scotia	22.3	23.9	53.8

Canso had a higher percentage of the population with no certificate, diploma or degree than Guysborough County and considerably more than the province. The percentage of the population with a high school level of education was similar between Canso, Guysborough County and the province. Although Canso had the lowest percentage of population with a post secondary education when compared to Guysborough County and the province, it did however have a higher percentage of its population with a post secondary education than a high school education.

Municipal Economic Health

Due to the extensive amount of out-migration, mostly due to the loss of fisheries related employment, the economies of Guysborough County and Canso are stressed (CBDC 2013; Gardner Pinfold 2011). However, new employment opportunities are arising in the natural gas, mining and shipping industries (CBDC 2013).

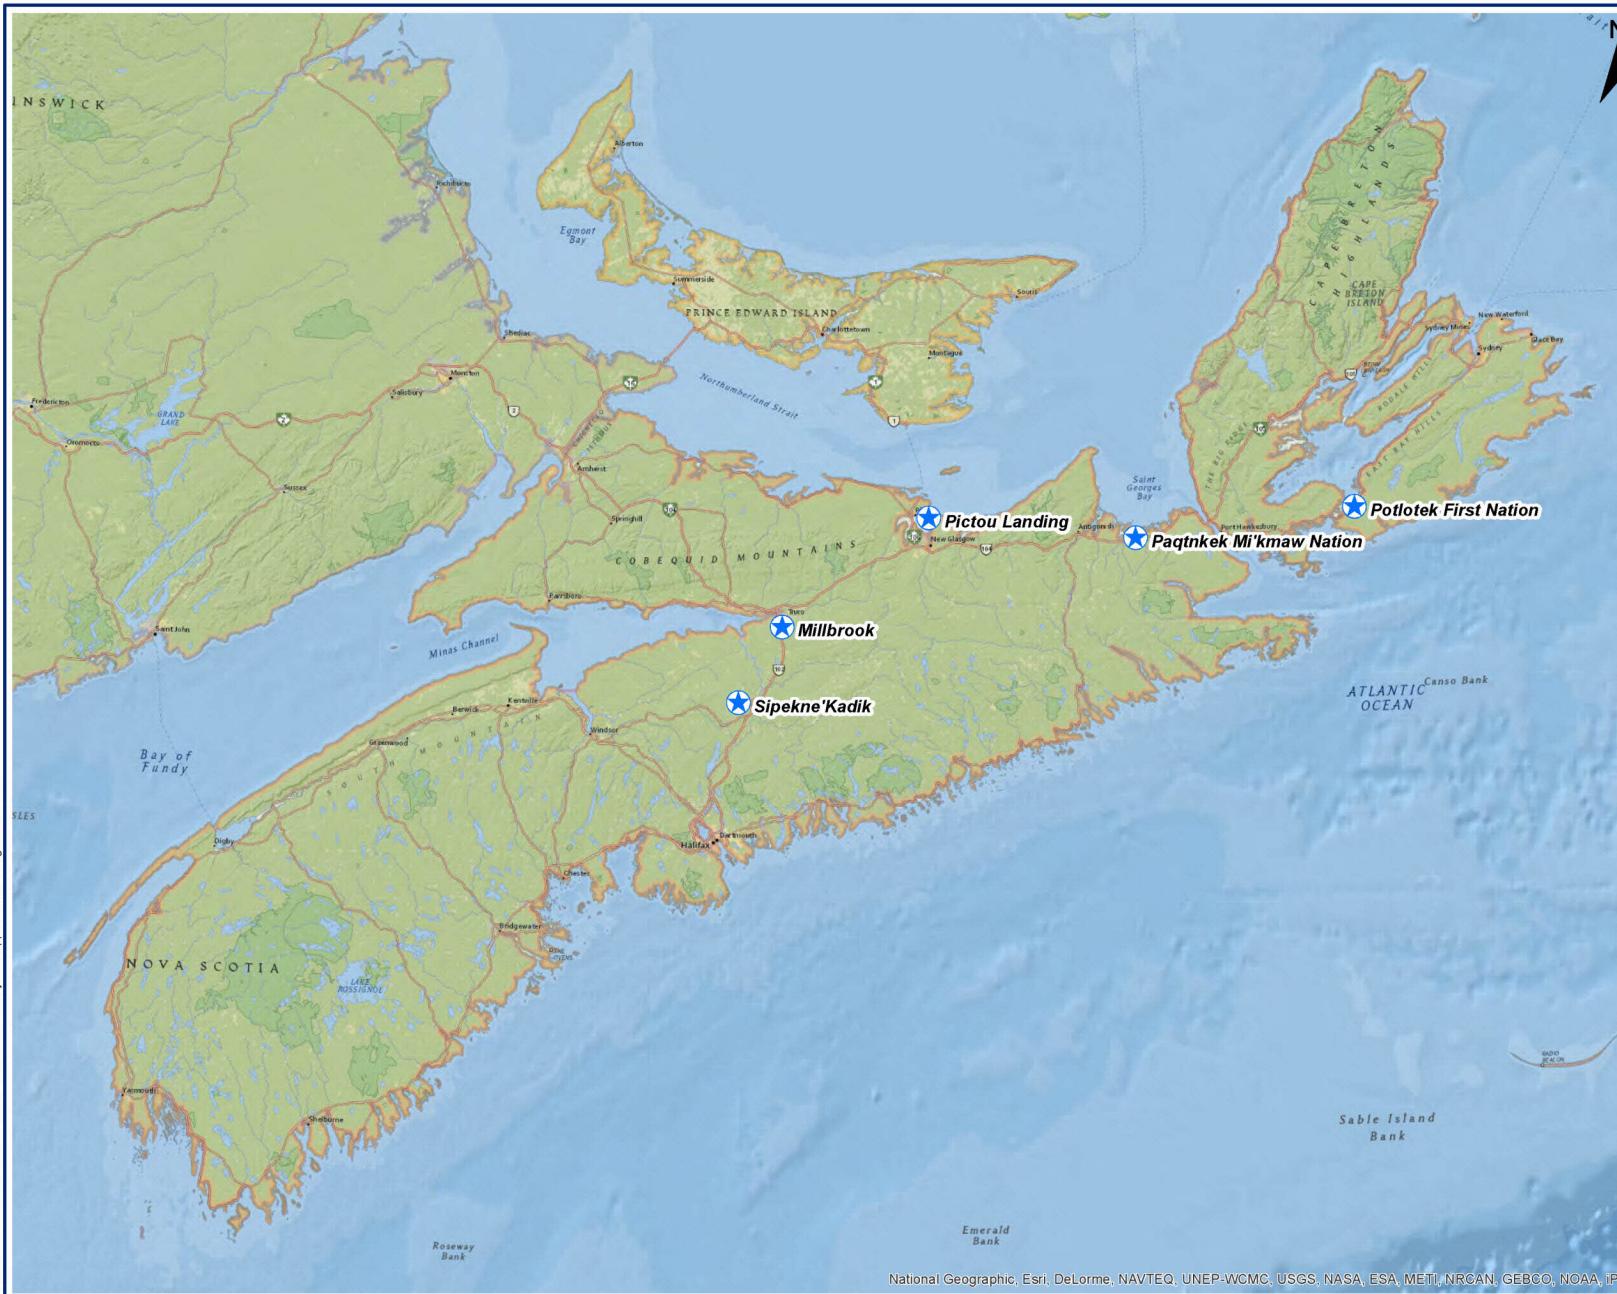

The 2011 – 2016 Strategic Plan of the Municipality of the District of Guysborough includes the following goals with the objective to balance economic opportunity and quality of life (MODG n.d.):

- To reverse the trend of population decline and have a 2% increase by 2015;
- To increase the establishment of new businesses; and create 200 new employment opportunities by 2015;
- To increase tax revenue by increasing the assessment base and increasing revenues from other sources;

- To maintain the quality of life for rate payers that may be affected as a result of potential dissolution of the Town of Canso;
- Improve service offerings to advance MODG as a liveable, healthy and sustainable municipality; and
- Strengthen internal operations.

6.8.3 First Nations Communities

A brief summary of the First Nation communities in close proximity to the Project site (**Figure 6.8-1**), which are known to have undertaken resource harvesting activities in the area are briefly described in the following sections.

6.8.3.1 *Paqtnkek First Nation*

The nearest mainland First Nation (Mi'kmaq) community is Paqtnkek First Nation (in Afton, NS). It is located 66 km northwest of Queensport in Antigonish County near Heatherton - mid way between the Canso Causeway and the Town of Antigonish.

The Paqtnkek First Nation has a registered population of 539, of which 376 live on Reserve. The Paqtnkek Band Council consists of six members. Paqtnkek First Nation administers three Reserve properties (Table 6.8-11).

**Table 6.8-11:
Paqtnkek First Nation Reserve Properties**

Reserve	Area	Location	Population	Date Established
Franklin Manor 22 (48% share with Pictou Landing First Nation)	212.5 ha (525 acres)	32 km. southeast of Amherst	0	March 3, 1865
Paqtnkek-Niktuek 23	218.1 ha (539 acres)	24 km. east of Antigonish	373	March 3, 1820
Welnek 38	43.4 ha (107 acres)	18 km. east of Antigonish	0	August 28, 1990

6.8.3.2 *Pictou Landing First Nation*

The Pictou Landing First Nation is located on the Northumberland Strait approximately 150 km from the project site. The community has a registered population of 649, of which 476 live on Reserve. The Pictou Landing Band Council consists of seven members. The Band Council administers 5 reserves (Table 6.8-12).

**Table 6.8-12:
Pictou Landing First Nation Reserve Properties**

Reserve	Area	Location	Population	Date Established
Boat Harbour West 37	98.2 hectares (243 acres)	8 km. north of New Glasgow	0	May 18, 1961
Fisher's Grant 24	142.7 hectares (353 acres)	10 km. north of New Glasgow	467	March 3, 1866
Fisher's Grant 24G	60 hectares (150 acres)	3.2 km. southeast of Pictou Landing	0	March 3, 1927
Franklin Manor 22 (part)	212.5 hectares (525 acres)	32 km. southeast of Amherst	0	March 3, 1865
Merigomish Harbour 31	14.2 hectares (35 acres)	12.8 km. east of New Glasgow	0	March 3, 1865

6.8.3.3 *Potolotek*

Located on Cape Breton Island, approximately 140 km from the Project site, the Potolotek First Nation (also known as Chapel Island First Nation) has a registered population of 710, of which

542 live on Reserve. The Potolotek Band Council consists of eight members. The Band Council administers two reserves (Table 6.8-13).

Table 6.8-13:
Potolotek First Nation Reserve Properties

Reserve	Area	Location	Population	Date established
Chapel Island 5	592.5 hectares (1,464 acres)	69 km. southwest of Sydney	481	July 1, 1792
Malagawatch 4 (1/5 share)	661.3 hectares (1,634 acres)	62 km. southwest of Sydney	0	August 2, 1833

6.8.3.4 Millbrook Band

The Millbrook Band is located near Truro, NS approximately 160 km from the project site). The Community, one of the larger Mi'kmaq communities in Nova Scotia has a 12 member Band Council. Millbrook First Nation administers seven Reserve properties (Table 6.8-14).

Table 6.8-14:
Millbrook First Nation Reserve Properties

Reserve	Area	Location	Population	Date established
Beaver Lake 17	49.4 ha (122 acres)	78.4 km southeast of Halifax	23	March 3, 1867
Cole Harbour 30	18.6 ha (46 acres)	9.6 km east of Halifax	194	March 3, 1880
Millbrook 27	302.0 ha (746 acres)	8 km south of Truro	847	March 3, 1886
Sheet Harbour 36	32.7 ha (81 acres)	91.2 km northeast of Halifax	15	March 3, 1915
Truro 27A	16.7 ha (41 acres)	Joined south of Truro town limit	0	March 3, 1904
Truro 27B	16.4 ha (41 acres)	Joined with 27A on south	0	March 3, 1907

6.8.3.5 Sipekne'katik First Nation

The Sipekne'katik First Nation is located near Shubenacadie, NS 240 km from the Project site. The Band has a registered population of 2,534 of which 1,222 reside on Reserve. Sipekne'katik has a 12 member Council which administers four Reserve properties (Table 6.8-15).

Table 6.8-15:
Sipekne'katik First Nation Reserve Properties

Reserve	Area	Location	Population	Date established
Indian Brook 14	1,234.2 ha (3,050 acres)	28.8 km southwest of Truro	1,084	July 8, 1820
New Ross 20	408.3 ha (1,009 acres)	64 km northwest of Halifax	0	March 3, 1820

Pennal 19	43.5 ha (107 acres)	67.2 km northwest of Halifax	22	March 3, 1858
Shubenacadie 13	412 ha (1,020 acres)	32 km north of Halifax	0	March 3, 1820
Dodds Lot	NA	NA	NA	NA
Wallace Hills	54.8 ha (135 acres)	NA	NA	NA

6.9 Land and Resource Use

6.9.1 Existing Land Use

The Project area is located in the Municipality of the District of Guysborough (MODG); approximately 10 km west of Canso, along the south shore of Chedabucto Bay. The Project area is bound to the north by Chedabucto Bay and to the south by a power transmission line. Provincial Route 16 runs parallel to the southern boundary of the site approximately 750 m away.

Lands immediately surrounding the Project area are largely undeveloped. In 2011 Guysborough County had a population of approximately 8,100 residences (GNS 2014b). The adjacent communities to the Project area, Half Island Cove, Fox Island Main and Upper Fox Island along Route 16, are rural in character and low in population density. Residential development in the vicinity of the Project is relatively sparse, with no residential structures within 500 m of the site boundary, 11 within 1 km, and fewer than 50 within 2 km. The nearest residence is located 700 m from the property boundary on the coast at the east end of Half Island Cove Road. The nearest residence on Route 16 is approximately 750 m from the property boundary. The separation between residences and blasting activity is even greater (and nowhere less than 800 m) considering the preliminary Project layout. For the first ten years or so of operation, the closest residence will be greater than 1.0 km from blasting since work will begin in the north end of the site and proceed in a southerly direction.

The Property is owned by the MODG and is relatively inaccessible, although ATV trails and the transmission line provide access to the granite highlands. Access to the lower coastal platform is more difficult but can be gained through footpaths or boats. An overgrown ATV trails can be used to access Black Point from the east.

Local residents report visiting the beaches, both east and west of Black Point, on an occasional basis (G. Krause pers. comm. 2014). The property has long been used for trapping by at least one local resident (J. Murphy pers. comm. 2014) and the presence of shotgun shell casings and a hunting blind suggests the site may be been used for hunting in the relatively recent past. Forestry is not actively practiced on the site, although forests to the east near Fox Island Main have recently been harvested; an activity mistakenly attributed to the Proponent.

6.9.2 Land Ownership and Tenure

The land hosting the quarry is owned by the Municipality of the District of Guysborough (MODG), as per a recently approved land exchange with the Province (Grant No. 23711) and expropriation of two private land parcels. The land is currently zoned Industrial Heavy I-2. The property is not now, nor has it ever been, used for a marine terminal. These lands have not been specifically designated for use as a marine terminal by the MODG.

6.9.3 First Nation Land and Resource Use

Current Land Use Activities

While it is known that the Project area was once occupied by Mi'kmaq families who frequented the area for its rich fishing, since the implementation of federal policies under the *Indian Act*, no Mi'kmaq communities (reserves) are located in or in close proximity to the Project area.

As noted in the Mi'kmaq Ecological Knowledge Study (MEKS) (MAPS 2013 – **Appendix K**), high mobility has always been a crucial characteristic of the land use patterns of Mi'kmaq individuals and families. However, as long as resources remained predictable, it was natural that hunters, fishers and harvesters of other natural resources tended to utilize areas that they are intimately familiar with and pass on this familiarity to their children. As a consequence, spatial land use patterns of Mi'kmaq families have in general remained fairly stable; despite the fact government policy was to centralize Mi'kmaq families onto a few discrete reserves. However motorized transportation and the associated infrastructure have enabled Mi'kmaq harvesters to have opportunity to conduct harvesting activities throughout the province.

A review of outstanding specific land claims was undertaken by Mi'kma'ki All Points Services during the preparation of the Mi'kmaq Ecological Knowledge Study (MAPS 2013). At the time of the study there were no specific claims pending within the Project area. This does not imply, however, that a specific land claim may not arise in the future.

It is understood that Crown consultation on new projects is conducted with all first Nations. This is due to the shared Rights of all Mi'kmaq to the resources upon which they have historically and are currently dependent. However, in keeping with the understanding of resource harvesting strategies (opportunistic) and centralization policies, it is likely that those most familiar with, and actively involved with resource use in the Project area will be located in the present day communities in closest proximity to the project site; the Paqtnkek, Potolotek, Pictou Landing, Millbrook and Sipekne'katik First Nations. This is consistent with the findings from the MEKS which noted that until the 1960s, the Project area and its resources were used by members of the three closest communities of Paqtnkek, Chapel Island (Potolotek) and Eskasoni (the largest Mi'kmaq community to which many families were relocated). It was also noted that families in Millbrook (to which many were located) had also lived in several communities in the Guysborough area.

Subsequently, as a result of Canada's centralization policies, there was diminished use of the area since harvesting activities began to focus on areas closer to the reserve lands. While it is understood that Mi'kmaq rights to harvest in all areas of Nova Scotia are important and protected, gradually there has been reduced involvement in the Project area by Eskasoni Band members with greater harvesting opportunities in the highlands and wilderness areas closer to the community and today the Project area sees little, if any, harvesting effort by community members.

The MEKS presented in **Appendix K** identifies lands and resources of use and interest to the Mi'kmaq of Nova Scotia in the Project area, and which may be potentially affected by Project development. Although no reports of on-going resource harvesting or use are recorded in the MEKS, the report notes the Property hosts certain resources that could be used by Mi'kmaq, should they choose to do so. The MEKS report has been presented to the Mi'kmaq Chiefs through the KMK. It should be noted that during Project conceptualization the Proponent

initiated an ongoing comprehensive Aboriginal Community Engagement Strategy (see Section 11.11 below).

As noted above, in addition to Paqtnkek some Band members from the Millbrook and Sipekne'katik First Nations have been involved in the resource harvesting in the lands and waters near the Project area, and are, as a result familiar with the region. Two other Mi'kmaq communities are also in relatively close proximity (<150 km) from the Project Site; Pictou Landing and Potolotek. Motorized transportation such as all-terrain vehicles, snowmobiles, pick-up trucks, engine-powered boats put the Project Area's resources within relatively easy reach from any of these reserve communities.

Site visits were conducted with Mi'kmaq Elders, harvesters, Chiefs, and organizational representatives on June 18, 2014, August 12, 2014 and October 27, 2014 with the objective of familiarizing community representatives with the Project, and to determine the level and extent of current use of the site for social, ceremonial or livelihood harvesting. Mi'kmaq community members were reported to have harvested several freshwater fishes (salmon, trout and eel) and hunted moose and deer, as well as various small game species in the region of the Project site. It had been noted in the MEKS that Mi'kmaq trapping activities occur within the general study area as well.

Based on the information compiled through the MEKS and findings during site visits, it is concluded that there is currently no direct Mi'kmaq use of the Project site for subsistence harvesting of food or furbearing in animals.

Mi'kmaq has continued to harvest a variety of plant species throughout Nova Scotia and the Project region is no exception. Harvesting of trees and plants such as maple, ash, birch as well as birch bark for tools, crafts and decorative items continue wherever these resources are known to occur. This is also true for blueberries, cranberries, strawberries and foxi berries. The MEKS also noted that several species of medicinal plants continue to be collected in the Guysborough region.

6.9.4 Protected Areas, Nature Reserves and Parks

The Restricted and Limited Land Use database maintained by NSDNR shows the following features in proximity to the proposed Project:

- Three private beaches protected under the Beaches Protection Act (Lower Half Island Cove 2.7 km west and Half Island Cove 3.9 km west, Fox Island Main 3.7 km east);
- Two Wilderness Areas: the Bonnet Lake Barrens Wilderness Area (6.9 km southwest) and the Canso Coastal Barrens Wilderness Area (1.7 km south and east);
- Third Lake Operational Non-Designated Parks and Reserve 4.2 km south and west.
- Designated Water Supply Area: Walsh or Wilkins Lake 4.5 km south and east; and
- Natural Watershed Municipal Surface Water Supply 3.65 km south and east.

These features are shown on **Figure 1.0-1**. Significant habitats and Important Bird Areas are shown on **Figure 6.4-3**.

6.9.5 Tourism and Recreation

There are a number of hiking trails and beaches, parks and wilderness viewing areas, museums and historic sites as shown on **Figure 6.9-1** (MODG 2014a). Some of these areas, such as the Canso Coastal Barrens Wilderness Area, several protected beaches (Lower Half Island Cove,

Half Island Cove, and Fox Island Main) and the Out of the Fog Lighthouse Museum in Half Island Cove are located within 5.0 km of the Project site. Recreational activity (trapping, ATV and snowmobile use) was observed on the Project site at the time of the winter bird survey in January 2011.

Activities located slightly further afield from the Project site include:

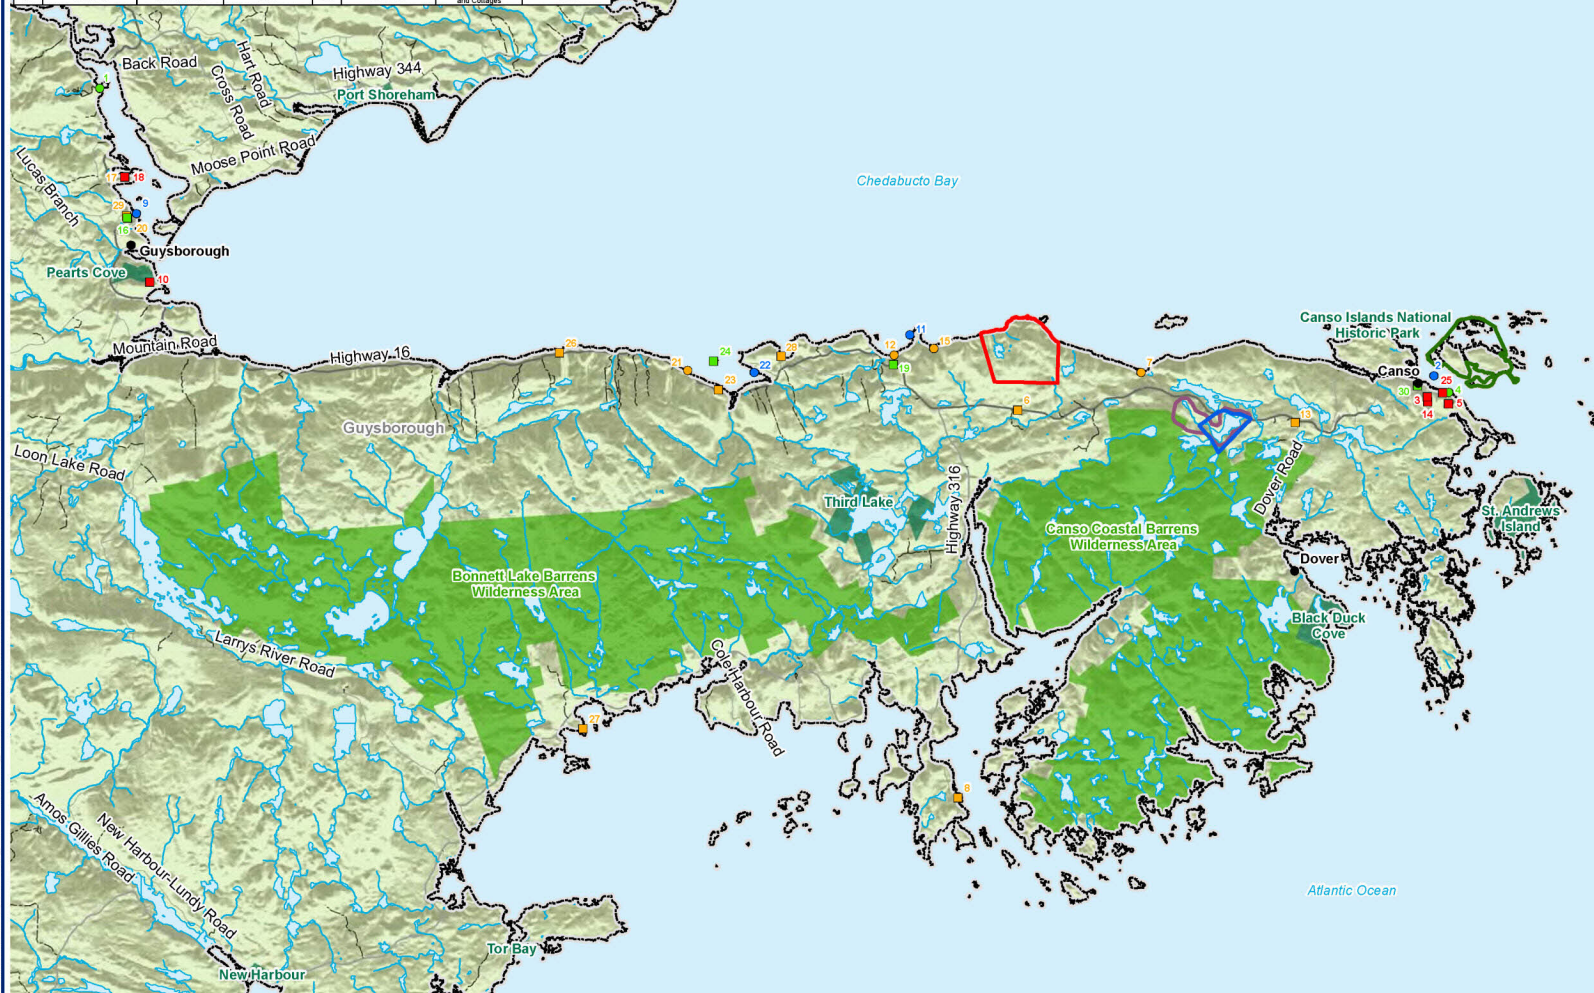

- Lighthouse Lookout and Park in Queensport (9.5 km east);
- the Whitman House museum (Nova Scotia 2014a) in the Town of Canso (10 km west) – provides visitors the history of Canso and eastern Guysborough;
- Queensport Beach (10 km west) – cobble beach with picnic tables overlooking the Queensport Lighthouse (GNS 2014e)
- Chapel Gully Trail (13 km east) – located in Canso, this 5 km trail allows for hiking and biking (GNS 2014f);
- Guysborough Nature Trail – Trans Canada Trail (26 km west)– a 44 km trail starting at Guysborough Harbour and is used for hiking, cross country skiing, snowshoeing and biking (Trail Peak 2014);
- Black Duck Cove Day Use Park (15 km south-east) – a 3.5 km shoreline hiking trail popular for birding (GNS 2014e);
- Canso Islands National Historic Park, located 15 km east of the Project site (<http://threeshoresnovascotia.ca>) - a National Historic Site, boat service is offered to the island to learn about the early European fishing port (PC 2011).
- Old Court House Museum (28 km west) - a museum for the local cultural heritage and an information centre for Guysborough County (GHS n.d.).

Hunting and fishing are popular activities in the MODG with big game hunting of deer and bear and inland and deep sea fishing. The area is popular for fishing blue fin tuna, shrimp, ground fish, scallop, snow crab and Atlantic mackerel (GCIFA 2014a).

The nearest recreational facilities include the Canso SportsPlex, which houses an arena, pool, and several sports fields. The Town of Canso also hosts a Royal Canadian Legion and a Lions Club. The Osprey Shores Golf Resort is located in Guysborough and is an all-encompassing resort with accommodation, food and beverage as well as a 2,691 yard, 9-hole golf course. The MODG has facilities to offer the community and visitors such as skating rinks, fitness centres, tennis courts etc. More information on local facilities can be found in Section 6.8. Guysborough is also home to local performing arts held in the Guysborough Masonic Hall, the Mulgrave Road Theatre Centre, Chedabucto Place Performance Centre and the Guysborough 300 seat performing arts space (MRT 2014).

BLACK POINT QUARRY PROJECT

TOURISM / RECREATIONAL PLACES

September 25, 2014	Rev	1.0	Figure No.
Project No.	210.05913.00000		6.9-1

SLR Consulting (Canada) Ltd.

Cultural events that occur in the neighbouring communities to the Project site include the annual:

- Stan Rogers Folk Festival (located within the Town of Canso) which usually occurs for several days during the month of July in honour of Canadian folk singer Stan Rogers. The festival is a popular event and has an attendance of over 10,000 people ; and
- Queensport Mackerel Derby which occurs late August (<http://www.authenticseacoast.com>).

Nova Scotia's shoreline is a popular destination for tourists including boaters. There are four marinas within 28 km of the Project site. The closest is Half Island Cove, 3.5 km to the west, which consists of one jetty. Queensport Harbour is 8.25 km to the west of the Project site and Canso Harbour is approximately 12.5 km from the site. Guysborough Marina is the largest of these and is located in Guysborough, 27.5 km from the site. The Guysborough Marina provides boat rentals including canoes and kayaks and also has a retail shop.

There are a range of tourist style accommodations in the MODG including motels, cabins, bed-and-breakfasts and campgrounds. Table 6.9-1 provides a list of accommodations and their location within the MODG.

**Table 6.9-1:
Accommodations within the District of Guysborough**

In 2010, Nova Scotia Tourism released the Visitor Exit Survey Community Report, which outlines the total visits (stopped or stayed) to Nova Scotia communities organized by tourist region, as well as "capture rates" of communities within these regions (Nova Scotia Department of Economic and Rural Development and Tourism, 2013). The communities of Canso and Guysborough were among the Eastern Shore communities examined. The Eastern Shore was visited by 7% of people during their trip to Nova Scotia. According to the 2010 Nova Scotia Visitor Exit Survey, the number one reason to visit the Eastern Shore was for a holiday, closely

followed by visiting friends or relatives. The activities most commonly undertaken were coastal sightseeing, hiking, and beach exploring.

6.9.6 Forestry and Agriculture

Clear cutting forest harvests have occurred to the west and south of the Project area in small patches (NSDNR 2007b) and forest harvesting is currently occurring to the east of the Project site along Highway 16 near the intersection with Fox Island Road. The forest within the Project site is largely non-merchantable and soil conditions do not allow for a viable agricultural practice (Section 6.1). No forestry is currently practiced on the Project site. The MODG has approximately 2,300 hectares in agricultural production which amounts to 1% of Nova Scotia's land in agriculture. None of this agricultural land is located in the Project area or neighbouring land (GNS n.d.).

6.9.7 Mining

There are no active mines on or adjacent to the Project site but there is a large aggregate mining operation near Mulgrave on the Strait of Canso (Martin Marietta's Auld Cove quarry located approximately 76 km northwest of Black Point) (MODG 2014a). Closer to the Project site, Chedabucto Aggregates is located in Half Way Cove approximately 12 km west of the Project site. Chedabucto Aggregates blasts, crushes, screens and trucks Goldenville Formation quartzite for sale to local markets.

The MODG is currently experiencing an increase in gold and rare earth metals exploratory studies. It is predicted that mining in this region will intensify in the near future (MODG 2014a).

6.9.8 Water Use including Groundwater

Currently there is no residential water use on the Project site. Residential homes adjacent to the Project site derive their water from drilled and dug wells (Section 6.2.1). The surface water uses near the Project site include recreational ocean and freshwater fishing (Queensport and Canso), commercial fishing in Queensport, Canso, and Half Island Cove (see Section 6.10.1). There are Designated Water Supply Areas (Walsh or Wilkins Lake 4.5 km south and east of the Project site) and Natural Watershed Municipal Surface Water Supply area located 3.65 km south and east of the Project site.

6.10 Fisheries and Aquaculture

6.10.1 Regulatory Framework

Fisheries and Oceans Canada (DFO) is the federal agency responsible for fisheries and fish habitat conservation and protection. DFO manages commercial fishing, licensing, conservation and enforcement through the *Fisheries Act* and associated regulations and policies. Commercial fisheries are managed by way of Integrated Fishery Management Plans (IFMPs), which in turn are based on information provided by DFO's Canadian Science Advisory Secretariat (CSAS) and other sources. The IFMP describes the management objectives for each fishery, the measures used to achieve these objectives, and the criteria by which the objectives are measured (DFO 2012b).

Under the *Fisheries Act*, the Atlantic Fishery Regulations (1985) provide management measures and define management areas for Atlantic coast fisheries. The Northwest Atlantic

Fisheries Organization (NAFO) Divisions are included in the Regulations, as are other fishing areas, such as Herring Fishing Areas, Crab Fishing Areas, Lobster Fishing Areas, Mackerel Fishing Areas and Shrimp Fishing Areas.

The Scotian Shelf comprises the main fishing grounds in Nova Scotia and has at least five zones and numerous stocks and sub-stocks. Chedabucto Bay is a component of NAFO fishing division 4W along the Scotian Shelf. The Project is located within NAFO Fisheries management Area 4Wd.

6.10.2 Commercial Fishing in Nova Scotia

At its peak in 2002-03, the landed value of commercial fisheries in the Scotian Shelf/Bay of Fundy region was \$800 million. The landed value has since declined to \$538 million in 2009 (DFO 2012b). A variety of fishing gears are used to capture over 30 different commercially saleable species, including bottom-contacting trawls and dredges, pots and traps, gillnets, seines and harpoons. Shellfish comprise about 80% of the fisheries by value (Gardner *et al.* 2009). The primary commercial shellfish species are lobster, scallop, snow crab and shrimp.

Groundfish contribute significantly to total landings (11% of landed value), but landings have drastically decreased since the 1970s and 1980s when this group accounted for over 50% of landed value. Cod, haddock, flatfishes and hake are now the leading commercial groundfish species (DFO 2012b).

Within the pelagic group (5% of landed value), herring, swordfish and tuna are the main species harvested. The relative importance of marine fisheries to the Nova Scotia economy has increased gradually over the past decade, with the contribution to the GDP rising from \$235 million in 1995 to over \$500 million in 2006 (Gardner *et al.* 2009; DFO 2012b).

6.10.3 Overview of the Guysborough County Commercial Fishery

In Guysborough County, the commercial fishing industry provides approximately 400 jobs in the form of small, independently owned businesses (GCIFA 2014b). There are over 200 registered fishing vessels ranging from 18 to 64.9 feet in Guysborough County, the majority of which are less than 34.9 feet in length (AMEC 2013). The core of the fishery is coastal, family-based, and uses small boats (SRSF 2001). In Guysborough, the estimated landed wharf value of all harvested species combined is over \$65 million annually (GCIFA 2014b).

Within the Project area, DFO lists two “core” small craft commercial fishing harbours (Queensport and Canso), and one “non-core” small craft commercial fishing harbour (Half Island Cove). Canso and Queensport are also managed harbours; they both have Harbour Authorities: incorporated, not-for-profit organizations responsible for managing, operating and maintaining the public fishing harbours (DFO 2011a).

Although almost all license holders who fish along the south shore of Chedabucto Bay are multi-species license holders (G. Boudreau, pers. comm. 2014), the lobster industry is the backbone of the fishing industry in Guysborough County and a significant economic activity in many coastal communities. The Project area is located in Lobster Fishing Area (LFA) 31A, with over license holders that are permitted to fish from Ragged Head all the way around to Whitehead, Guysborough County (G. Boudreau, pers. comm. 2014).

A number of commercial species are taken in Chedabucto Bay. As noted, this includes lobster as well as shrimp, herring, mackerel, crab, scallop, tuna, squid and sea urchin (please see

below). Within Chedabucto Bay, fishers are allowed fixed gear only: herring nets, shrimp, lobster and crab traps. The only exception is applied to scallop fishers, who do not use fixed gear and tuna fishing.

Historically, cod, mackerel, and herring, were valued commercial species taken in Chedabucto Bay and the Bay was used as a spawning area by Atlantic cod and herring. Spawning may still occur, although herring spawning has not been documented in the area since 2009. Juvenile herring and hake use the Bay for nursery habitat. Mackerel and herring also utilize the Bay for over-wintering habitat (Gromack *et al.* 2010). In addition to spawning, and rearing habitat Chedabucto Bay is also an important feeding ground for herring.

Historic records indicate the Bay supported commercial fisheries for lobster, crab, shrimp, and shellfish. The area has supported lobster for many years, and in more recent years commercial landings have increased. The Bay also supports a healthy population of northern shrimp (Gromack *et al.* 2010).

6.10.4 First Nations Fisheries

Overview

In 1990, the Supreme Court of Canada's Sparrow decision upheld the Aboriginal right to fish for food, social and ceremonial purposes (DFO 2012b). In response, DFO initiated the Aboriginal Fisheries Strategy to provide a framework for the management of fisheries for food, social and ceremonial purposes (DFO 2003). In 1999, the Supreme Court affirmed a treaty right to hunt, fish and gather in pursuit of a "moderate livelihood" in its landmark Marshall decision (DFO 2012b; AFN 2011).

Since 1999 DFO has implemented several programs to promote the integration of First Nations into Atlantic Canadian fisheries. The Marshall Response Initiative (MRI) was created to provide Mi'kmaq and Maliseet First Nations with increased access to the commercial fishery through the provision of licenses, vessels and gear. The Aboriginal Aquatic Resource and Oceans Management (AAROM) program was instituted to facilitate the participation of Aboriginal groups in advisory and decision-making processes for oceans and fisheries resource management (DFO 2008c). The Atlantic Integrated Commercial Fisheries Initiative (AICFI) was developed to enhance corporate governance and business planning while offering a vehicle for future small scale fisheries asset acquisition (AFN 2011). Since the Marshall decision, Aboriginals throughout the Maritimes have participated in training, established administration, governance and business infrastructure, and have substantially increased their involvement in Atlantic commercial fisheries (APCFNC 2009).

Historically, First Nation fishers primarily exploited snow crab and lobster (Cooper *et al.* 2010) but considerable effort has been made in recent years to diversify the First Nation fishery. Currently, the most productive species in Atlantic Canada are bluefin tuna, lobster, scallop, shrimp and snow crab, with lobster and snow crab dominant in terms of licenses and shrimp and snow crab dominant in terms of economic return (AFN 2011; APCFNC 2009).

The landed value of Aboriginal fisheries tripled between 2000 and 2006, while fishing employment increased 60% between 2000 and 2007. In 2009, 11% of Aboriginal jobs in Atlantic Canada were in the fishing sector (APCFNC 2009). Aboriginal fishing licenses generated an economic return of approximately \$35 million in 2009 compared to just over \$4 million in 1999 (APCFNC 2009).

At this time, it appears that fishing assets have been successfully transferred to First Nation communities, promoting employment opportunities and economic return to many groups. Cumulatively, these initiatives have resulted in quantitative improvements in terms of employment and revenue in First Nation communities. These programs have also reportedly developed a more knowledgeable and sophisticated appreciation of the industry, fisheries management, and corporate governance at the community level (AFN 2011).

The First Nation fishery has experienced considerable growth along with a number of challenges over the past decade. In 1999 (pre-Marshall decision) 316 fishing licenses were held by First Nations in Atlantic Canada. By 2009, this had increased to 1,238 (APFNC 2009). Challenges to the industry over this period included low market price for lobster, which has created pressures on the demand for licenses, and economic loss in the snow crab fishery (AFN 2011). Additional challenges emerged with respect to how these resources were managed, implemented and controlled (Cooper *et al.* 2010). Nevertheless, the commercial fishery continues to represent a long term, sustainable industry for many Nova Scotia Mi'kmaq communities (Cooper *et al.* 2010; APCFNC 2009).

Mi'kmaq Fisheries

Those communities which have been involved in the local commercial groundfish, lobster, snow crab, tuna, swordfish, and mackerel fisheries include: Acadia, Potlotek, Eskasoni, Sipekne'katik, Membertou, Millbrook, Wagmatcook, Waycobah, Pictou Landing and Paqtnkek. All the Nova Scotia bands and the Native Council of Nova Scotia in the Maritimes Region are authorized to harvest in this area for food, social and ceremonial (FSC) purposes.

The MEKS noted that marine resources were reported to be harvested along the Study Area portion of the Chedabucto coast. These include mackerel, herring, cod, haddock, urchins, mussels, oysters, clams, as well as snow crab in deeper waters. The sandbar extending between Fox Island and the mainland was also noted as a productive shellfish bed.

Several Mi'kmaq communities are currently fishing marine species for livelihood purposes. Some of this activity was apparently initiated following the Supreme Court of Canada's decision on the *R v Marshall* case that confirmed recognition of Mi'kmaq communal rights to fish for livelihood purposes. These efforts are managed under the Department of Fisheries and Oceans through communal commercial licenses, some of which are issued for the large fishery management areas along the Nova Scotia eastern shore.

Telephone interviews were conducted with the fishery managers from each of the communities which have licenses along the eastern shore to determine if any fishing effort is targeted in or near the Project site. Table 6.9-2 provides the findings from these interviews. Representatives from the Guysborough County Inshore Fishermen's Association were also contacted to determine local knowledge of fishing activity of Mi'kmaq fishers.

**Table 6.9-2:
Project Area Mi'kmaq Commercial Fishing Activity**

Band	Contact	Commercial Fishing activity – Eastern Shore
Millbrook	Adrian Gloade	1 sea urchin license 4 snow crab licenses Possible tuna fishing if fishery is not successful nearer Canso.
Shubenacadie	Brendan Maloney	No lobster licences in LFA 31
Waycobah	Phil Drennan	1 shrimp trap license in Chedabucto Bay Lobster licenses in Chedabucto Bay Elver fishery throughout area to Alder Point Snow crab fishery in Zone 24 Groundfish offshore: silver hake, redfish, hagfish, snow crab 1 offshore shrimp trawl license
Chapel Island	Charles Doucette	1 urchin license, 2 shrimp, 3 crab, 2 lobster
Eskasoni	Leonard Denny	10 mobile shrimp licenses, 14 snow crab license in Zones 23, 24
Membertou	Hubert Nichols	No active licenses in Guysborough- Canso area. They do fish tuna in the area. Remaining fisheries are far offshore.
Wagmatcook	Preston Bernard-	3 active snow crab licenses off shore. Also some tuna fishing in the area.
Paqtnekek	Marina Sark	No active licenses in the area.

6.10.5 Species Harvested in the Project Area

Lobster LFA 31A

Lobsters breed in summer to fall. Eggs hatch two years after breeding, generally in the July-August. Larvae swim in the water column for 4-6 weeks before settling to the bottom and seeking shelter. Six to nine years are required for lobsters to reach legal size. Mature lobsters generally move from shallow to deep water in the fall and from deep to shallow in late spring (DFO 2004).

As noted, the Project area is located within LFA 31A; the fishing season is currently April 29 to June 30. In 2011 there were 73 licenses within LFA 31A, each with a 250 trap limit (DFO 2011b); there are currently 68 active licences (Table 6.10-1 reports 68 active licences in 2013).

Lobster prefer rocky seabed habitat. In the Project area, this habitat is generally confined to nearshore areas, typically within 250 m of the shore. Based on conversations with members of the GCIFA, in the vicinity of the Project site there are at least three lobster fishers who habitually the nearshore zone between Black Point and Gaulman Point.

Lobster fishermen are guided in their patterns of gear deployment not only by the abundance of lobster, but also by the weather and sea conditions, and levels of risk to gear, boats and human lives (Hatcher *et al.* 2013). Fishermen tend to deploy and redeploy gear throughout the season in response to weather patterns; the progressive depletion of catchable lobster; and the migration of lobster amongst various habitats. Despite these variations, the lobster fishermen tend to be conservative, typically fishing the same areas in the same fashion year after year (Hatcher *et al.* 2013).

A study of lobster fishing practices near the proposed Donkin mine in Cape Breton helps to provide a context for lobster fishing in Chedabucto Bay. Hatcher *et al.* (2013) note:

- The time-averaged average annual landings of per boat in the lobster fishery (near the Donkin mine) ranges from approximately 12,000 to 18,000 lbs (5,450 to 8,180 kg).
- Large (~25%) inter-annual variations in landings from the lobster fishery are not uncommon due to a variety of biological and environmental factors. For example, catch rates in the 2013 season were “exceptionally high” in comparison to the 2012 fishing season.
- On average, approx. 60% of each season’s lobster catch is landed during the first half of the 2 month season, even though effort intensity (# pot-hauls per day) remains essentially constant throughout the season.
- The number of days fished declines towards the end of most seasons, and the proportion of undersize and spawn females increases markedly during the second half of the season. Prices paid to fishermen at the dock also tend to decrease as the season progresses.

Indicators of lobster stock health for in LFAs 28-32 are mainly positive (DFO 2011b). Landings in 2010 in LFAs 28-32 (3,866 t) and the mean for the last 3 years (4,224 t) were well above the median for 1985-2004 (822 t). An index of egg production for LFA 31A is currently high (DFO 2011b). Table 6.10-1 lists landings and licences in for LFA 31A from 2011 through 2013.

**Table 6.10-1:
Lobster Selected Landings and Active Licenses - 2011-2013**

License Species	Fishing Area	Year Landed	Active Licenses	Landings (kg)
Lobster	LFA 31A	2011	67	757,385
Lobster	LFA 31A	2012p	67	806,998
Lobster	LFA 31A	2013p	68	670,824

Note: Data for the years 2012 and 2013 is preliminary (p).

Source: DFO Maritimes Region, Policy and Economics Response to Data Request

The Guysborough County Inshore Fishermen's Association (GCIFA) is at the forefront of research regarding sustainable lobster fishing (GCIFA 2013). The GCIFA has partnered with St. Francis Xavier University, the Gulf Nova Scotia Bonafide Fishermen's Association (Lakevale), the Mi'kmaq Fish and Wildlife Commission (Afton), and the Interdisciplinary Studies in Aquatic Resources (Antigonish) to achieve a series of fisheries conservation objectives established by the Association.

Since the late 1990s, the GCIFA has undertaken a number of at-sea sampling programs on an annual basis. Research programs are monitoring and assessing a number of factors that contribute to the productivity of the fishery: size, sex, health, by-catch, weather, water temperature, egg development/release/retention larval survival and other parameters. These programs provide an overall index of the commercial catch as well as other species interactions by way of by-catch. The GCIFA provides their data sets to the Canadian Fisheries Research Network on lobster biology and health (GCIFA 2013; GCIFA 2014c).

Shrimp

The Scotian Shelf shrimp fishery occurs off Eastern Cape Breton and mainland Nova Scotia. In 2006, the industry supported 20-25 vessels (Gardner Pinfold 2006). In addition to the mobile shrimp fishery (i.e., mobile vessels that tow shrimp trawls along the ocean bottom), there is also an inshore trap fishery that uses baited wire mesh traps similar to lobster traps. This fishery was developed by inshore fishermen in Guysborough and Richmond Counties. All trap shrimp fishermen operating in Chedabucto Bay fish out of Canso (G. Boudreau, pers. comm. 2014).

Shrimp are found at depths of 150 - 600 m off the east coast of Nova Scotia, and in shallower waters in Chedabucto Bay. They are an important food source for Atlantic cod, Greenland halibut, skates, snow crab and harp seals (Garner Pinfold 2006). In the Study Area, based on conversations with fishermen who harvest in the area, shrimp are typically trapped south of the established shipping lanes and within the deeper water bounded by the 40 fathom depth contour (**Figure 6.10-1**). The proposed shipping route between the marine terminal and the established shipping lane has been modified to avoid these preferred shrimping grounds.

**Figure 6.10-1:
40 Fathom Depth Contour Near the Project Site**

Within Shrimp Fishing Area 15, there are 14 trap licences in total, with an allocation of 100 traps each (the total trap limit is 800). Five of the licences are located in the north of Chedabucto Bay, eight in the south, and one along the eastern shore just south of the bay. The trap fleet is active primarily from late fall through winter (DFO 2014b).

Within Chedabucto Bay, the shrimp fishery started in 1991 and currently employs six or seven active vessels (MacAndrew 2014). The fishing season is open year round but is most intensive from November through April when water temperatures are coldest. Shrimp prefer soft and muddy seafloor such as are found in central portions of Chedabucto Bay (MacAndrew 2014).

Fishermen set up to 100 hundred modified lobster traps in strings of 10, on the muddy bottom of the Bay in depths of 50 to 60 fathoms. These depths correspond to the approximate southern side of the primary shipping lane accessing the Strait of Canso. The traps are baited with herring; shrimp gain entry through a funnel on top of the trap. Smaller shrimp slip back out through the netting, ensuring no waste in by-catch, and a re-generation of the species (MacAndrew 2014).

Over the past several years, catches averaged about 800 pounds per day per vessel (ranging from 300 to 1000 pounds) over the winter season. In 2012, Chedabucto Bay shrimp fishers

landed 500,000 lbs of shrimp representing a value of \$725,000.00 for this fishery (EAC 2012). Table 6.10-2 lists the landings and active licences for this species from 2011 through 2013.

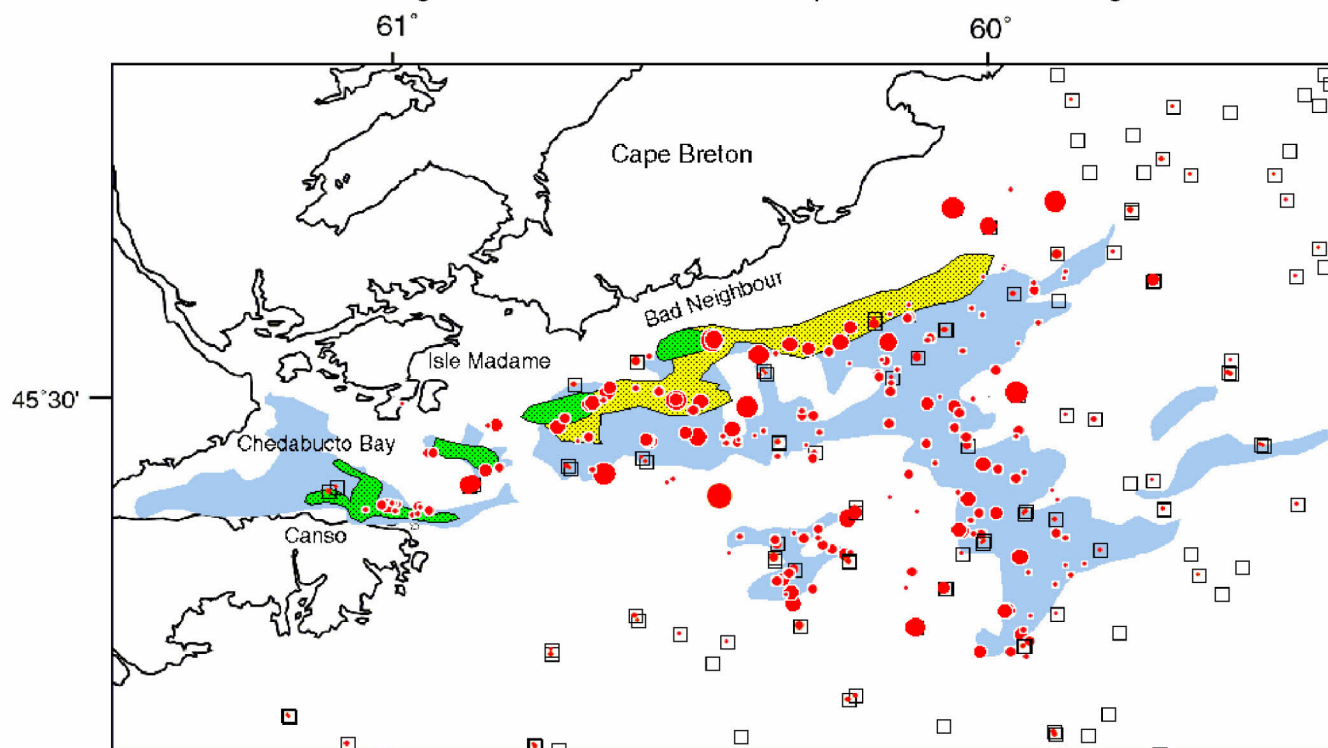

Figure 6.10-2:
Commercial Shrimp Trapping and Trawling; Relative Crab Catch Sizes

Source: Koeller *et al.* 2007 (Note: Shrimp trapping areas in green, trawling in yellow and relative crab catches in red with larger circles representing larger catch sizes.)

Note to Figure 6.10-2: Areas where commercial shrimp trapping (green shading) and trawling (yellow shading) are conducted in Chedabucto Bay and the Bad Neighbor, from log book data. Also shown are cumulative catches of DFO-industry shrimp surveys in June (1995-2006), DFO-industry crab surveys in fall (2004-2005) and DFO groundfish surveys in July (1999-2006) in relative numbers (red circles). Larger circles indicate larger catches, open squares indicate null catches. Shrimp habitat (La Have clay) is shown in light blue.

Table 6.10-2:
Shrimp Selected Landings and Active Licenses - 2011-2013

License Species	Fishing Area	Year Landed	Active Licenses	Landings (kg)
Shrimp, <i>Pandalus Borealis</i>	SFA 15 (4WD & 4WU only)	2011	23	797,893
Shrimp, <i>Pandalus Borealis</i>	SFA 15 (4WD & 4WU only)	2012p	19	680,423
Shrimp, <i>Pandalus Borealis</i>	SFA 15 (4WD & 4WU only)	2013p	23	540,696

Note: Data for the years 2012 and 2013 is preliminary (p).

Source: DFO Maritimes Region, Policy and Economics Response to Data Request

Herring and Mackerel

The Project area is located within Herring and Mackerel Fishing Areas 19. Mackerel, squid and herring are caught in the same type of trapnet, which is set in a fixed location. For this fishery, DFO assigns a fixed location for each mackerel trap or berth; typically a fisherman may operate from one to three berths. Mackerel are also caught locally using jiggers (GCIFA 2014a).

The herring fishery in Chedabucto Bay is subject to fishing restrictions (fishing season and quotas) outlined in the Canadian Atlantic Herring Southwest Nova Scotia Rebuilding Plan – Atlantic Canada 2013 (DFO 2014c). The fishing season in Chedabucto Bay (HFA 19) is November 1 to March 1.

A shared, Atlantic-wide quota is assigned to the mackerel fishery. Commercially caught mackerel must attain a conditional length established by DFO to qualify for harvest. Most mackerel is taken for use as bait for the lobster, shrimp and crab fishery, but there is also a food fishery for fall mackerel (GCIFA 2014a).

DFO landing and license data, as well as the exact trap locations for these species harvested in HFA 19 and LFA 19 were withheld to preserve stakeholder confidentiality. Local fishermen report that no trapnets are located within several kilometers of the Project Site. Trapnets are reported in Queensport Harbour (8 km west), Philips Harbour (7 km west) and near Fox Island in Indian Cove (5 km east).

Snow Crab

In 2005, many Crab Fishing Areas (CFAs) and subareas were merged. Formerly, CFA 24 East included Chedabucto Bay but this area is now contained within the larger South East Nova Scotia division (CSAS 2013).

On the Scotian Shelf, commercial size snow crab are typically found in deep, cold water at depths ranging from 60 to 280 m and temperatures from -1 to 6°C; they are fished on muddy or sand-mud bottoms (CSAS 2013). In the Project area, snow crabs are caught using wire conical traps set mainly in offshore waters extending to Sable Island (GCIFA 2014a).

The snow crab fishery has been in existence on the Scotian Shelf since the early 1970s. Total landings increased to record levels of approximately 10,000 t each year in the early 2000s and have surpassed these previous highs since 2009. Landings in 2012 for the South East Nova Scotia division were 11,707 t (CSAS 2013). Table 6.10-3 lists the landings and active licences for this species from 2011 through 2013. Figure 6.10-2 above shows relative crab catch sizes within Chedabucto Bay.

Table 6.10-3:
Snow Crab Selected Landings and Active Licenses - 2011-2013

License Species	Fishing Area	Year Landed	Active Licenses	Landings (kg)
Crab, Snow	CFA 24 (4WD & 4WU only)	2011	26	1,380,906
Crab, Snow	CFA 24 (4WD & 4WU only)	2012p	33	1,610,928
Crab, Snow	CFA 24 (4WD & 4WU only)	2013p	29	1,645,730

Note: Data for the years 2012 and 2013 is preliminary (p). 4WU denotes effort within 4W without a sub-area selected.

Source: DFO Maritimes Region, Policy and Economics Response to Data Request.

Tuna

A prosperous bluefin tuna fishery is present in Chedabucto Bay, within NAFO division 4Wd. The bluefin tuna caught in Atlantic Canada are part of the western Atlantic stock. These migratory stocks are managed under the jurisdiction of the International Commission for the Conservation of Atlantic Tunas (GCIFA 2014a).

There are 10 license holders exploiting the Canso and Queensport areas as well as 40+ transient license holders from the Gulf of St. Lawrence and PEI (GCIFA 2014a). The bluefin tuna fishery uses rod-and-reel gear or tended hook and line, and this gear is restricted to a maximum of four lines per vessel and one hook per line (DFO 2014d).

The commercial fishing season extends from late spring into late fall with fishing period for individual fleets opening and closing at various dates. Traditionally, the fishery begins with the migration of bluefin into Canadian waters in early July and usually continues until mid-November. The majority of landings occur between late July and late September (DFO 2014d).

There are two tuna fleets each with GCIFA members that share the International Bluefin Tuna Quota:

1. Nova Scotia Fundy Based 4WD Tuna Fishery. This fishery has 10 licenses managed by the 4WD Tuna Fishery Association. The fishery is restricted to rod and reel gear and has a set percentage of the international quota that is fished competitively by the 10 license holders. The season is open from August 1st to December 31st but is typically fished in late August, September and October (GCIFA 2014a; G. Boudreau, pers. comm. 2014).
2. Gulf Nova Scotia Based Tuna Fishery. This fishery has 10 licenses that are managed under the Gulf Nova Scotia Tuna Association. It is also restricted to rod and reel gear but receives a percentage of the international quota that is competitively fished by all Gulf Based licenses (GCIFA 2014a).

The non-licensed (catch and release) tuna fishery also provides revenue for local charter boat operators and owners of lodges and other accommodations.

**Table 6.10-4:
Bluefin Tuna Landings and Active Licenses - 2011-2013**

Scallop

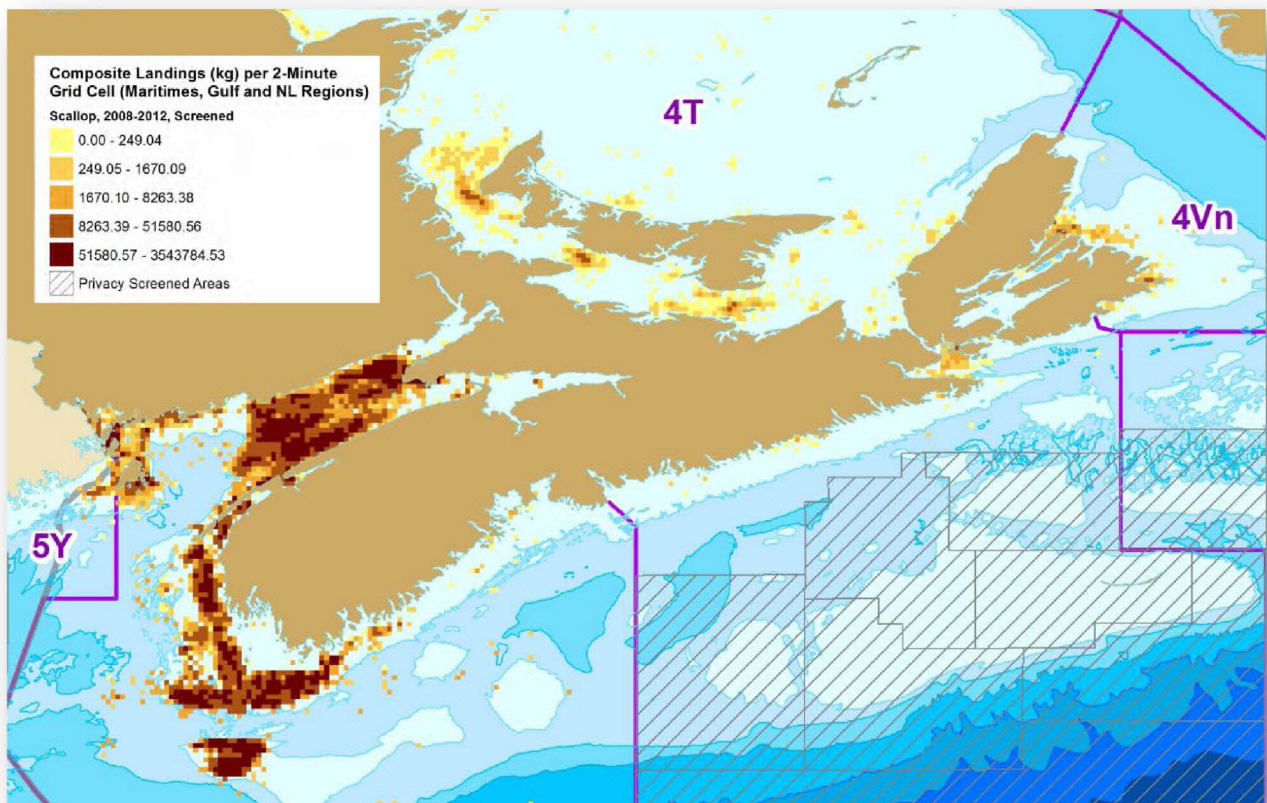

Members of the GCIFA hold licenses for Scallop Fishing Area East of Baccaro for inshore scallop drag. The license holders have a quota per license and are managed by DFO through dockside monitoring, at sea trip logs. According to the GCIFA, many of the scallop licenses are inactive due to high cost of monitoring and low quota access (GCIFA 2014a). Table 6.10-5 lists the landings and active licences for sea scallop from 2011 through 2013. Scallop landings in and around Chedabucto Bay are shown on Figure 6.10-3.

Table 6.10-5:
Sea Scallop Selected Landings and Active Licenses - 2011-2013

Other Species - Sea Urchin, Rock Crab, Marine Plants, Eels

According to the GCIFA, fishermen based in Canso and along the south shore of Chedabucto Bay hold licences to harvest other species, such as sea urchin, rock crab, marine plants, and eels, but these licenses are not currently active (GCIFA 2014a).

To the extent that these data are available from DFO, Table 6.10-6 lists the landings and active licences for these other species from 2011 through 2013.

6.10.6 Recreational Fisheries

Mackerel is the primary salt-water recreational species in the area (GCIFA 2014a), but catch and release recreational bluefin tuna fishing is also popular with local residents and tourists from Europe and the United States.

In Guysborough County, the freshwater inland lakes and streams support recreational speckled (brook) trout, brown trout, rainbow trout, landlocked salmon, chain pickerel, white perch, and yellow perch fisheries. The fishing season generally runs from April 1 to September 30. Recreational fishing in tidal waters extends from April 15 to September 30, to protect sea-run speckled trout, brown trout, and Atlantic salmon populations (NSFA 2014b).

6.10.7 Aquaculture

There are no aquaculture sites currently active in Chedabucto Bay (NSFA 2014a). There are a number of active aquaculture sites in Whitehead Harbour, primary for blue mussel and sea scallops. The nearest aquaculture site is located near Upper Whitehead, approximately 7.0 km south of the Project site. Records indicate a license was issued in 2002 for a 1.25 ha sea urchin site in Canso Harbour off the coast of George Island, but this lease is not currently active (NSFA 2014a).

A joint project was undertaken in 2001 to develop a coastal aquaculture planning tool for the Guysborough County Regional Development Authority (Stantec 2009). The study consisted of a constraint mapping exercise using Geographic Information System (GIS) tools to identify areas for potential aquaculture site development. The constraint mapping was based on a range of criteria, including biophysical conditions such as temperature, salinity, depth, oxygen and turbidity, and other practical constraints such as navigation routes, parks, and closed areas (Stantec 2009).

6.11 Shipping and Navigation

6.11.1 Overview of Commercial Shipping

Commercial shipping over the Scotian Shelf consists primarily of tankers and general, bulk and containerized cargo carriers. The Shelf is also crossed by fishing vessels, cruise ships and government vessels. The primary commodities transiting the region include crude oil and gas, minerals and chemicals, paper and forest products, coal and coke, and a variety of containerized goods (DFO 2005).

For safety, the *Vessel Traffic Services Zones Regulations* under the *Canada Shipping Act* establish Vessel Traffic Services (VTS) zones along Canada's coasts (TC 2014). Shipping in these zones is monitored by the Canadian Coast Guard's Marine Communications and Traffic Services (MCTS). A Pre-Arrival Information Report (PAIR) is required to be filed 96 hours prior to arrival in Canadian waters, as per the *Marine Transportation Security Regulations* in accordance with the instructions set out in the Canadian Coast Guard's *Radio Aids to Marine Navigation*. The MCTS logs movements of larger vessels but non-reporting traffic includes a significant proportion of tugs, fishing and recreational vessels.

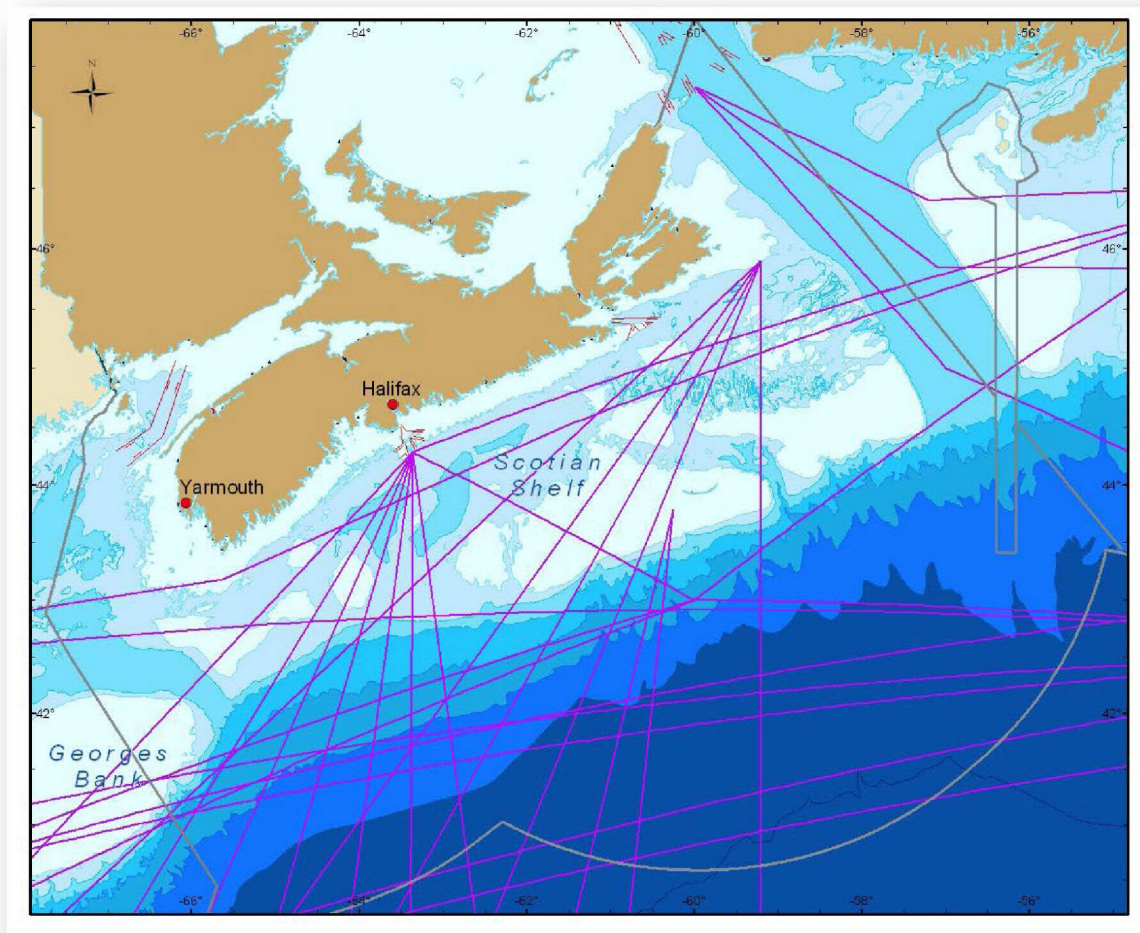

To receive clearance to enter Canadian waters, ships of 500 tonnes gross tonnage or more must report to an MCTS officer 24 hours before entering the VTS zone. The incoming vessel reports information about the ship and its intended route, including any defects and deficiencies relevant to potential marine pollution, as well as position, speed, destination, etc. This allows any safety or environmental concerns to be addressed before ships enter Canadian waters. Vessels within the zone must also make regular reports at specified calling-in points (TC 2014).

Vessel Traffic Services does not operate like air traffic control. It is the ship master's responsibility to safely guide the ship; however the master must comply with a direction given by a MCTS officer.

Figure 6.11-1 illustrates the main shipping routes over the Scotian Shelf and shows (in red) the entrance lanes to Halifax Harbour and Chedabucto Bay. The entrance lanes or "approaches" to Chedabucto Bay and the calling in points referenced above are shown in more detail on **Figure 6.11-3**.

There are four regional shipping traffic patterns on the Scotian Shelf (DFO 2005):

1. international shipping between Europe and the eastern seaboard of the US and Canada;
2. international and domestic shipping along the coast of Nova Scotia bound to and from the United States, Bay of Fundy, Gulf of St. Lawrence and Newfoundland;
3. shipping through the Cabot Strait and into the St. Lawrence Seaway; and
4. traffic associated with the major ports of Halifax, Saint John, Port Hawkesbury (Strait of Canso) and Sydney.

**Figure 6.11-1:
Scotia Shelf Shipping Routes**

Source: DFO 2005

On the Strait of Canso, the Strait Superport consists of the Mulgrave Marine Terminal and the Port Hawkesbury Pier. In 2011, it handled 23.8 million tonnes of cargo, slightly less than the most active year, 2009, when 33.5 million tonnes of cargo passed through the port (Strait Superport 2014). Most of the cargo is associated with the petroleum facility operated by Statia Terminals. Bulk exports of gypsum, paper products, aggregate and imports of coal make up the

balance. The Mulgrave Marine Terminal primarily services the offshore oil and gas industry (DFO 2011c).

Shipping density over the Scotian Shelf for the year 2000 is shown in Figure 6.11-2 (DFO 2005). The data were compiled by DFO and are taken from the Eastern Canada Vessel Traffic Services Zone (ECAREG) system. The Figure illustrates the relatively high density of traffic, shown in red transiting Chedabucto Bay.

**Figure 6.11-2:
Scotian Shelf Shipping Density (2000)**

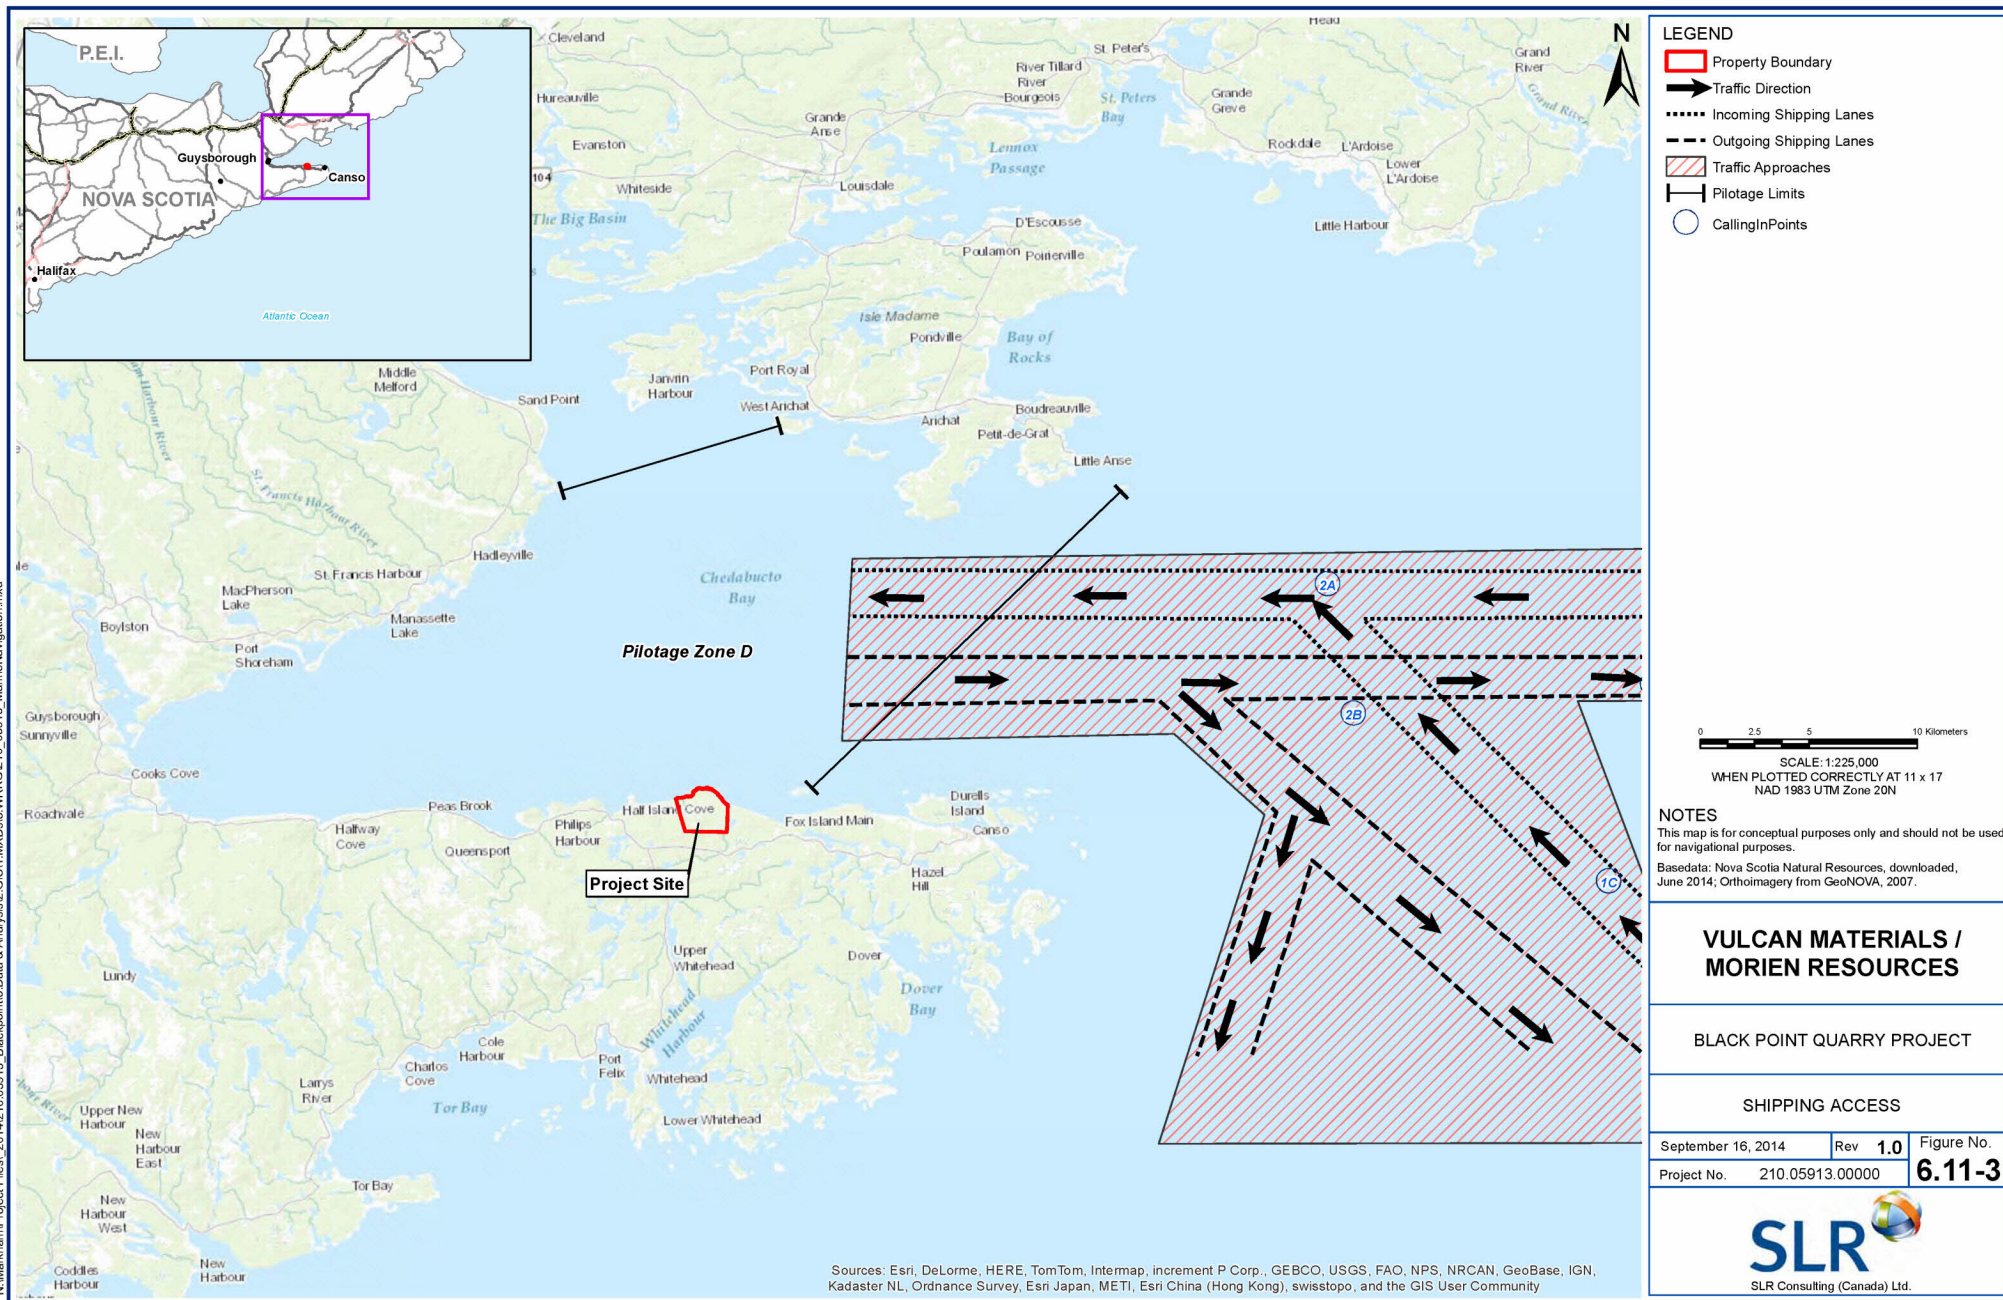

Source: DFO 2005

6.11.2 Accessing Chedabucto Bay

The Project site is located within Compulsory Pilotage Area Zone D as defined by the *Pilotage Act* (**Figure 6.11-3**). This means that incoming and outgoing vessels from the marine terminal must be attended by an experienced licenced pilot, who advises the ship master on navigational matters within the Pilotage Area.

The pilot boarding station that Proponent vessels will use for Chedabucto Bay is termed the "Southern Approach" and is located at 45°24'00N / 61°01'00W (APA 2013). The Southern Approach pilot station is assigned to vessels over 225.5 length overall (LOA). Proponent vessels will typically be on the order of 245 m LOA.

N:\Markham\Project Files\2014\210.05913 Blackpoint\3 Data & Analysis\2 GIS\1 MXDs\3.WRK\210_05913_MarineNavigation.mxd

An MCTS officer contacts the incoming vessel to describe when the pilot will board, what speed to maintain, and on which side the pilot boat will approach. The pilot arrives at the pilot boarding station on the Atlantic Pilotage Authority (APA) pilot boat. The pilot boards the Proponent's vessel and discusses the passage plan with the master and the bridge team. A pilot's duties are to aid the ship master, and give advice on the passage. In effect, the navigational command of the vessel, issuing helm and engine orders to the bridge team is assumed by the pilot (AMEC 2013). Despite this, the ship master remains ultimately responsible for ship operation and safety.

When a Proponent's vessel is preparing to leave the Black Point marine terminal, a pilot will board the vessel at the terminal. Tugs will be used to guide the ship as it leaves the berth until it reaches a safe, outbound position. The pilot remains on board providing navigational advice then leaves once the outer pilot station is reached or at some other mutually agreed upon position. MCTS continues to monitor the progress of the vessel and the vessel continues to report until it is clear of the VTS zone.

6.11.3 Vessel Activity in Chedabucto Bay

The Strait of Canso area has four ports: Port Hastings, Port Hawkesbury Port Tupper and Mulgrave. These ports, as well as Inhabitants Bay, come under the Harbour Master's jurisdiction. Port Hawkesbury and Mulgrave are the busiest ports, while Inhabitants Bay and Chedabucto Bay usually have one or two vessels at anchor. During the fall through winter storm season it is not uncommon to see additional vessels at anchor in Chedabucto Bay, waiting for the poor weather to pass (G. Freer, pers. comm. 2014). With two mooring locations servicing vessels up to 400,000 DWT, Port Tupper is a deep water, ice free harbour with access to rail, road and airport services (NSBI 2015).

As noted in Section 6.10.3, there are over 200 registered fishing vessels ranging from 18 to 64.9 feet in Guysborough County, the majority of which are less than 34.9 feet in length. It is difficult to estimate the number of fishing and recreational vessels in Chedabucto Bay since some of these vessels do not need to report to the Harbour Master. A general estimate is approximately 30-35 vessels (G. Freer, pers. comm. 2014).

In 2013 there were 577 large vessels recorded in Chedabucto Bay (harbour tugs and pilot vessels are not included in this count). Tankers and bulk carriers comprise the majority of this traffic and approximately 80% of these vessels are pilot-assisted. In 2014 (to mid-September) 422 vessels were recorded. May, June and July are typically the busiest months (G. Freer, pers. comm. 2014). Included within this traffic count are pilot-assisted vessels anchored in the Bay engaging in ship to ship transfers of coal.

6.11.4 Ballast Water Exchange and Pollution Prevention

Ballast water taken aboard ships in foreign ports may contain organisms that are not native to Nova Scotia, and which could cause harm to local ecosystems. Under the *Ballast Water Control and Management Regulations*, all ships entering Canadian waters must exchange ballast water outside of the Exclusive Economic Zone (200 nautical miles from shore), treat their ballast water, discharge their ballast water to a reception facility, or retain their ballast water on board ship (TC 2011).

In addition, an international convention regarding ballast water has been adopted by the International Maritime Organization (IMO); this convention could enter into force as early as 2015 (G. Anderson pers. comm. 2014). Under IMO's International Convention for the Control and Management of Ships' Ballast Water and Sediments, all vessels will be required to report and treat ballast water using an IMO approved method.

The International Convention for the Prevention of Pollution from Ships (MARPOL) is the main international convention covering pollution prevention in the marine environment by ships from operational or accidental causes.

The MARPOL Convention was adopted by the IMO in 1973 and has been updated by amendments through the years. The Convention includes regulations aimed at preventing and minimizing pollution from ships - both accidental pollution and that from routine operations - and currently includes six technical Annexes. Special areas with strict controls on operational discharges are included in most Annexes:

Annex I: Regulations for the Prevention of Pollution by Oil. Covers prevention of pollution by oil from operational activities as well as from accidental discharges.

Annex II: Regulations for the Control of Pollution by Noxious Liquid Substances in Bulk. Describes the discharge criteria and measures for the control of pollution by noxious liquid substances carried in bulk; no discharge of residues containing noxious substances is permitted within 12 miles of the nearest land.

Annex III: Prevention of Pollution by Harmful Substances Carried by Sea in Packaged Form. Contains general requirements for the issuing of detailed standards on packing, marking, labeling, documentation, stowage, quantity limitations, exceptions and notifications. For the purpose of this Annex, "harmful substances" are those substances which are identified as marine pollutants in the International Maritime Dangerous Goods Code or which meet the criteria in the Appendix of Annex III.

Annex IV Prevention of Pollution by Sewage from Ships. Contains requirements to control pollution of the sea by sewage; the discharge of sewage into the sea is prohibited, except when the ship has an approved sewage treatment plant or when the ship is discharging comminuted and disinfected sewage using an approved system at a distance of more than three nautical miles from the nearest land.

Annex V Prevention of Pollution by Garbage from Ships. Prohibits the discharge of all garbage into the sea.

Annex VI Prevention of Air Pollution from Ships. Sets limits on sulphur oxide and nitrogen oxide emissions from ship exhausts and prohibits deliberate emissions of ozone depleting substances; designated emission control areas set more stringent standards for SOx, NOx and particulate matter.

To enforce these IMO provisions and Canadian regulations, Transport Canada performs aerial surveillance to detect pollution from ships. In 2011-2012, crews observed more than 12,000 vessels and detected 135 pollution occurrences nationally, with an estimated total volume of 1,014 litres of oil (TC 2014). Transport Canada investigations have led to numerous successful prosecutions against marine polluters over the years, with some financial penalties reaching more than \$100,000.

6.12 Archeological Resources

An archaeological resource impact assessment of the proposed Black Point Quarry Project was conducted by Davis MacIntyre & Associates Limited in 2011, followed by a second resource assessment in 2014 to address specific recommendations made in 2011 (**Appendix L**). Historical maps and manuscripts and published literature were consulted at Nova Scotia Archives and Records Management in Halifax. The Maritime Archaeological Resource Inventory, held at the Nova Scotia Museum's Heritage Division, was searched to understand prior archaeological research and known archaeological resources neighbouring the Project site. Additionally, two archaeological reconnaissance surveys of the Project site were conducted; the first in 2011 and the second in 2014.

6.12.1 Provincial

The history of human occupation in Nova Scotia has been traced back approximately 11,000 years to the Palaeo-Indian period or Sa'qewe'k L'nu'k (11,000 – 9,000 years before present or BP). The only significant archaeological evidence of Palaeo-Indian settlement in the province exists at Debert / Belmont in Colchester County. The Saqiwe'k Lnu'k period was followed by the Mu Awsami Kejikawe'k L'nu'k (Archaic period) (9,000 – 2,500 years BP) which was succeeded by the Woodland / Ceramic period or Kejikawek L'nu'k (2,500 – 500 years BP). The Woodland period ended with the arrival of Europeans and the beginning of recorded history (DMA 2011).

The initial phase of contact between First Nations people and Europeans, known as the Protohistoric period, was met with various alliances particularly between the Mi'kmaq and French. The Mi'kmaq inhabited the territory known as Mi'kma'ki or Megumaage, which included all of Nova Scotia and Cape Breton, Prince Edward Island, New Brunswick (north of the Saint John River), the Gaspé region of Quebec, part of Maine, and south-western Newfoundland. A historical Mi'kmaq presence is well documented in Guysborough County and specifically in the vicinity of Canso, less than 15 kilometres east of the Project site.

It is thought that the French began fishing off the coast of Nova Scotia as early as 1504 and possibly earlier (DMA 2011). Activity on land was coastal and seasonal, consisting of trade with the native Mi'kmaq and the use of beaches to dry fish for the long voyage back to France. The fishery continued to be profitable for centuries, supplying the French, English, and Basque seamen who sailed along these coasts.

6.12.2 Black Point

Prior to 1721, a British Government regulation decreed that all tracts of forest land containing trees suitable for ship masts should be set aside as Crown Reserves (DMA 2011). It is possible that this regulation is related to the surprising scarcity of land grants within the study area. Indeed, only two grants appear to have been made: the first to Michael Fogarty and the second to Peter James Lukeman (DMA 2011).

In 1820, William Timothy Fogarty and his wife arrived on the shores of the Chedabucto Bay, in the area now known as Fogherty Head, from Ireland. In 1821, their first son, Mickal (Michael), was born. In 1858, five years after the death of his father William, Michael sought a land grant from the Nova Scotia government for this area, which started succession of the land in the Fogarty family (Frank Fogarty, pers comm. May 2014).

Between 1820 and 1928, the area south of Fogherty Head was home to four generations of the Fogarty family. During this time, a number of children were born on the property from the original family line and the ensuing families. Given the number of births on the property, it is possible that there were multiple deaths at the property from a variety of causes for both young and old. Due to the poverty of the time, and the distance to Canso, it is also possible that burials could have occurred on the property (Fogarty Family 2014).

Until 1857 the “Stagecoach Road” between Crow Harbour and Canso ran along the coast, passing close to Fogarty Head and Black Point. The rocky nature of this road meant that passage in the summer by buggy or wagon was nearly impossible. However, it appears that in the 1870s at least two houses were located in or near the eastern end of the study area. When the new road was built farther inland it encouraged settlement along level and fertile ground off the hard coastline (DMA 2011).

Oral history recounts that Black Point had a vibrant settlement in the late nineteenth century. The settlement included the Black Point School, and one oral report suggests that a Roman Catholic Church may have been located in the area (DMA 2011). Another source stated that by the late 1800’s, the area had both a church and a school, with the church being destroyed by fire in the 1930’s resulting in the loss of all records (Fogarty Family 2014). Also, another clue that may corroborate a church having stood in the vicinity is a vital statistics record showing that Murdock McNeil and Bridget Eaton were married on July 2nd, 1891 at Black Point, Guysborough County under a Roman Catholic licence (NSHVS 1891).

Around 1890, Joseph Fogarty (2nd generation Fogarty) began a fishing operation at near Fogarty Head with his sons. After Joseph Fogarty’s death, the fishing operation was continued by his son Vincent, and Vincent’s sons. The fishing operation continued long after the Fogarty’s moved to Hazel Hill in 1928, with Vincent and his sons commuting to the site, and even spending extended periods of time living south of Fogherty Head during fishing (Fogarty Family 2014).

Local residents also report that Martin Daley and his son Vincent were the last residents of Black Point. In his later years, Martin lived at nearby Fox Island or Fox Island Main during the week, working as a fisherman. On weekends, he would return to Black Point to live with his son. The two were farmers and fishermen, a type of dual employment that was not uncommon on the coast of Nova Scotia during the nineteenth and early twentieth century. Sometime after the 1930s, the Daley house and barn were demolished. Both were located in a meadow with a brook running down its centre, where one local resident reported pasturing his family horse in the summers (DMA 2011).

Sometime after all of the residents of Black Point had moved to Fox Island Main or further afield, John Rhynold and his son reportedly flew a flag on Black Point in memorial to John’s mother, who was born at Black Point (DMA 2011). Additionally, a descendent of the Lukeman family kept a cabin on his family property at Fogherty Head, and used to visit the site each year (DMA 2011).

6.12.3 Project Site

As noted above, an Archeological Resource Assessment of the Project site was completed by archaeologists of Davis MacIntyre & Associates Limited in July, 2011 (**Appendix L Attachment A**). The goal of the study was to establish the layout and conditions of the Property in order to determine whether or not a complete walkover survey would be necessary. During

the assessment survey, no evidence of cultural activity was observed; however, the entire site was not accessed as is typical in a reconnaissance level survey (DMA 2011). The authors recommended that (a) the historic coastal road to Canso be further evaluated for archaeological resources and (b) the two on-site water bodies (the outlet of Fogarty Lake and the barachois⁵ immediately south of Black Point) be examined for potential Mi'kmaq activity.

This Resource Assessment report was received and reviewed by the Nova Scotia Heritage Division. They found the report acceptable and agreed with the recommendations stated within **(Appendix L Attachment A)**.

As a follow up to recommendations made in 2011, archeologists from Davis MacIntyre and Associates Ltd. revisited the site in October 2014. The study team also contacted the Fogarty family for additional background information and ultimately focused their efforts on the southern coastal platform where house foundations had been reported (Fogarty Family 2014; J. Murphy pers. comm. 2014). The 2014 Archeological Resource Assessment is presented in **Appendix L Attachment B**.

A number of items of historical interest that indicate past habitation of the coastal platform were recorded during the 2014 Resource Assessment. In total, six probable house foundations were identified, comprising three on the former Lukeman property, one on the former Fogarty property and two located in the center of coastal platform, possibly associated with the Daly family. Other historical artifacts include stone piles, apple trees and the remnants of an iron stove (**Appendix L**). No evidence of human burials was recorded (i.e., headstones, burial-like mounds or depressions, etc.) although the study team identified an area near the west coast of the Property that reportedly would have been suitable for burials. In addition, no evidence of Mi'kmaq use of the Property was observed; the archeological study team noted that for a variety of reasons the Property was likely not as attractive to Mi'kmaq peoples as other nearby areas. The study team also noted that beach areas that may have been used in passing by Mi'kmaq are high energy environments that typically do not preserve historical remains.

The Project layout as currently conceived will easily and effectively avoid historical foundations on the former Lukeman and Fogarty properties. Avoidance is the preferred follow-up activity when potential historical artifacts are discovered (DMA 2014). In contrast, the two probable house foundations located in the center of the coastal platform will undoubtedly be disturbed during site preparation in advance of processing plant construction. Recommendations to address these sites and other general mitigation measures to protect archeological resources are presented in Section 7.16.

⁵ A **barachois** is a term used in Atlantic Canada to describe a coastal lagoon separated from the ocean by a sand or shingle bar. The "barrachois" near Black Point is a freshwater wetland rather than a coastal lagoon.

7.0 ENVIRONMENTAL EFFECTS ASSESSMENT

7.1 AIR QUALITY AND CLIMATE CHANGE

7.1.1 Overview

Air quality concerns associated with the generation of dust have been raised by community residents and the Mi'kmaw, and so Air Quality is identified as a VC. Air quality is also a pathway to the food chain via the transport of dust and deposition of contaminants on vegetation and surface water. Air quality within the quarry is of interest to provincial workplace health and safety regulators. Outside the Property boundary ambient air quality standards are established in the provincial *Air Quality Regulations* and enforced by NSE.

Vehicles and generators used at the Project site will produce greenhouse gases (GHGs) from the combustion of fuel. GHG emissions are associated with climate change and have been the subject of provincial regulation and policy initiatives.

7.1.2 Boundaries

The boundaries for the air quality assessment are based on the nature of the activities expected to generate air emissions at the Project. These activities mainly include site preparation, construction and operation of the processing plant, access road, marine terminal and quarry.

7.1.2.1 Temporal Boundaries

A summary of the activities associated with air emissions and the estimated duration of each activity is presented below. Initial quarrying south of the processing plant area will generate construction materials that will be used for surfacing the processing plant area and access road, and eventually for building the marine terminal.

- Pre-Mining Activities (Phase 1)
 - Establish access and haul roads, site preparation: 3 years (2017-2020)
 - Mobilization and set up of portable processing plant (Phase 1): 1 year (2017-2018)
- Mining Related Activities (Phases 2-5)
 - Commissioning of portable processing plant (Phase 2): 2 year (2018-2020)
 - Construction of marine terminal: 1 year (2019-2020)
 - Expansion of portable processing plant (Phase 3): 2 years (2020-2022)
 - Construction of fixed processing plant (Phase 4): 1 year (2021-2022)
 - Expansion of fixed processing plant (Phases 5): 4 years (2026-2030)
 - Operation of access and haul roads, marine terminal, quarry: end of construction to end of life (~2065)
- Closure, decommissioning, and final reclamation: estimated at 2 years but may be extended.

Quarrying will take place nine months out of the year weather permitting and ship loading will take place on a year-round basis. Operating hours will be 24 hours a day, with 16-hours of production (two 8-hour shifts) and one 8-hour maintenance shift per day. The specific hours each day that production will occur may vary. Blasting will be performed between 8 am and 6 pm. Blasting is expected to occur 2 – 3 times per week and will not occur on statutory holidays

or Sundays. Ship loading may occur 24 hours per day with a maximum anticipated duration of 2 days per week, and equipment maintenance may occur at any time during the day if needed, although most maintenance activities will be scheduled for the 8-hour maintenance shift.

The greatest emissions to the air are expected to occur several years following start-up of the full scale fixed operating plant in Phase 5 (2022). Based on forecasted sales, annual emissions will gradually increase from Operating Year 1 (2018) and reach the expected maximum annual rate no earlier than 2024.

With respect to climate change, the hydrological assessment incorporated possible climate change scenarios extending 70 years in the future; 70 years is thus adopted as the temporal boundary for the climate change aspects described here.

7.1.2.2 *Spatial Boundaries*

The spatial boundaries for the air quality assessment are threefold: the Project Area (within the Project property boundary where workplace health and safety regulations dominate), the Affected Area, where provincial ambient air quality standards must be met, and the larger Study Area, including the shipping routes between the marine terminal and established shipping lanes, where more diffuse Project impacts may be expected.

Climate change is a trans-boundary global issue, but the climate change assessment of this Project is related to provincial initiatives and emissions reduction targets.

7.1.2.3 *Administrative Boundaries*

Air quality within the Project site is regulated by the province through the *Workplace Health and Safety Regulations*, which establishes the air quality conditions needed to maintain worker health. Air quality outside of the Project site is also regulated by the province, which may set air quality emissions standards for industrial operations in the industrial operating permit. Maximum permissible ground level concentrations of various air pollutants, including Total Suspended Particulate (TSP or dust) are listed in Schedule A of Nova Scotia's *Air Quality Regulations*. Federal regulators may reference similar limits established under the *Canadian Environmental Protection Act*.

7.1.2.4 *Technical Boundaries*

Technical boundaries represent theoretical or actual limits to the Project team's ability to assess a VC, pathway or receptor. For the Air Quality and Climate Change VC, no technical boundaries were encountered. Prediction of ambient air quality changes is based on air dispersion modeling (**Appendix O**), experience with granite quarry design and operation, quantification of total potential emissions, existing climate and ambient air conditions, and proximity to nearby receptors.

7.1.3 Threshold for Determination of Significance

Particulate matter is the primary criteria air contaminant of concern for the Project.

Air contaminants that are of most concern from project operations include total suspended particulate (TSP), particulate matter less than 10 and 2.5 microns in diameter (PM10 and PM2.5, respectively), nitrogen oxides (NOx), carbon monoxide (CO) and sulphur dioxide (SO2).

The Nova Scotia Air Quality Regulations (179/2014) establishes limits on TSP, SO2, nitrogen dioxide and CO. In addition, the Canadian Council of Ministers of the Environment issues Canada-wide issued standards for particulate matter less than 2.5-micron in diameter (PM_{2.5}). These standards are used as thresholds for determination of significance and provided in Table 7.1-1.

A significant adverse effect is defined as an exceedance of the Nova Scotia or CCME ambient air quality standards at a residential or commercial location outside the property boundary, where the exceedance is due to emissions from the operation and the event occurs more than twice in the period of time that the standard is based.

**Table 7.1-1:
Ambient Air Quality Standards**

Jurisdiction	Pollutant	Averaging Time	Current Standard	Standard 2015	Standard 2020
NSE	TSP	24- Hour	120 µg/m ³	--	--
		Annual	70 µg/m ³	--	--
NSE	SO2	1-Hour	900 µg/m ³	--	--
		24- Hour	300 µg/m ³	--	--
NSE	NO2	1-Hour	60 µg/m ³	--	--
		Annual	400 µg/m ³	--	--
NSE	CO	1-Hour	34600 µg/m ³	--	--
		8Hour	12700 µg/m ³	--	--
CCME	PM _{2.5}	24- Hour	--	28 µg/m ³	27 µg/m ³
		Annual	--	10 µg/m ³	8.8 µg/m ³

A quarry, where the annual production exceeds 500,000 tonnes, is required to consider all National Pollutant Release Inventory (NPRI) substances for reporting to the NPRI, regardless of the hours worked by employees.

There are no national or province-wide Nova Scotia standards or limits for greenhouse gas emissions. In 2007, the Nova Scotia Government passed the *Environmental Goals and Sustainable Prosperity Act (EGSPA)*, an innovative piece of legislation on sustainable development and economic prosperity. EGSPA contains the first hard caps of greenhouse gas (GHG) emissions in Canada. Among other actions, the *Act* requires a reduction in provincial GHGs of 10% below 1990 levels by the year 2020.

In order to lessen the province's dependency on imported fossil fuels and reduce greenhouse gas and air pollutant emissions, the Government of Nova Scotia in 2009 tabled *Toward a*

Greener Future - Nova Scotia's Climate Change Action Plan followed by the 2010 *Renewable Electricity Plan*. These reports describe an approach to integrate progressively larger amounts of low-emission renewable energy into the provincial electrical grid. The *Climate Change Action Plan* contains goals for meeting a target greenhouse gas reduction of 5 megatonnes annually in order to meet the 2020 GHG reductions regulated in *EGSPA*. To achieve these reductions, the Government of Nova Scotia has imposed emissions caps on electricity generation sector and worked to increase the efficiency of the transportation sector.

7.1.4 Effects of the Project on Air Quality

Dust emissions (total particulate matter [TPM], total suspended particulate [TSP], particulate matter up to particle size 10 microns [PM_{10}] and particulate matter up to particle size 2.5 microns [$PM_{2.5}$]) are the main air quality issue for quarry construction and operation. These particulate matters emissions have the potential to be transported off-site and if not mitigated may reduce visibility or contribute to a number of health problems, such as asthma, decreased lung function and coughing or difficulty breathing.

The dust emission sources associated with the Project are:

- wind erosion of material storage piles and exposed areas
- crushers
- screens
- material loading/unloading
- material conveyors and transfer
- blasting
- overburden removal, and
- vehicle traffic (haul roads).

Combustion emissions from equipment, vehicles, and ships occur during construction and operation of the Project. Criteria air contaminants associated with combustion emissions are sulphur dioxide (SO_2), nitrogen oxides (NO_x), volatile organic compounds (VOCs), carbon monoxide (CO), and particulate matter (PM). Fuel combustion in equipment, vehicles, and ships are sources of Project greenhouse gas emissions, which include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O).

On a temporary basis, a minimal amount of air pollutants are also generated from wind-blown dust and fuel combustion during the construction and decommissioning phases.

The emissions from the project are summarized in Table 7.1-2 below. These emission rates represent peak production anticipated for each phase.

**Table 7.1-2:
Total Criteria Pollutant Emissions from Quarry and Processing Plant**

tonnes/year							
Project Phase	Total Suspended Particulate (TSP)	Particulate Matter <10 microns (PM10)	Particulate Matter <2.5 microns (PM2.5)	Nitrogen Dioxide (NO2)	Carbon Monoxide (CO)	Volatile Organic Compounds (VOCs)	Sulfur Dioxide (SO2)
Phase I	6.16	1.83	0.76	30.64	24.99	3.39	1.48
Phase 2	22.78	6.31	2.70	54.12	36.15	6.12	1.60
Phase 3	47.09	14.58	2.92	77.50	62.48	8.33	2.00
Phase 4	99.84	33.42	6.19	91.76	92.15	9.87	2.00
Phase 5	114.56	37.44	7.28	105.35	109.07	11.08	2.80

(source: Vulcan Materials Company)

These estimates were calculated using emissions factors from Environment Canada¹ and US EPA², and Tier 4 Off-Road engine emission standards from US EPA document Emissions Factors for Nonroad Engine Compression-Ignition Engines³. The emissions address the sources described previously for the quarry and processing plant. Greenhouse gas emissions are described in Sections 3.3.10 (Air Emissions) and 3.3.12 (Emissions to Atmosphere from Marine Operations).

Emissions from aggregate transport vessels while they are maneuvering for berthing and while berthed for loading are provided in Table 7.1.3. These emission levels are not significant as the ships operate on auxiliary power when berthed and are only in transit for berthing a short period of time.

(source: Vulcan Materials Company)

In general, based on the source release type, emissions quantity, and meteorological conditions, concentrations will likely dissipate well below significant levels within 500 m of the source (see results from air dispersion modelling study below). This means most of the effects of the Project on air quality will be within the Project Area and may extend up to 500 m into the Affected Area. The processing plant sources and stock piles are located well within 500 m of the Property boundary. Quarrying may occur near the property boundary, but the nearest public receptors are 720 to 750 m away from the boundary and even farther from quarry face. The emissions from the shipping lane will be beyond the Project Area; however, the vessels are not significant sources of emissions and the impacts from these are expected to be insignificant.

The highest concentrations at the Property boundary from all fugitive dust sources (except wind erosion off disturbed areas and piles) are, somewhat counterintuitively, usually generated during times of low wind speeds when the air is calm. With respect to wind erosion, high winds may push dust further afield, but the additional turbulence keeps concentrations low. High wind speeds (winds greater than 8.8 m/s), which occur about 24% of the time, will cause greater wind erosion and dust transport. Nearly half of these winds come from west-northwest and northwest. However, it is just over 1 km to the nearest public receptor in this direction and additional mitigation will be implemented at wind speeds greater than 8.8 m/s. Low winds blowing during calm conditions to the east, west, and south produce the highest dust concentrations at the Property boundary; these wind conditions occur approximately 6% of the time (EC 2006a; 2009).

Fugitive dust emissions are greatest during hot and dry conditions. The proximity of the Project site to the ocean leads to relatively high moisture and low temperature; and both high and low speed winds blowing toward the ocean from the sea breeze effect. The hottest daily maximums (greater than 20° C) occur in July and August and the average rainfall during these months is still above 80 mm. The majority (over 50%) of the winds during these two months are blowing

from the south or southwest, carrying emissions into the Bay and away from the nearest receptors (residential buildings and roads).

In order to quantify air contaminant dispersion during quarry operations, an air dispersion modelling study was undertaken (**Appendix O**). Dispersion modeling was completed using AERMOD, developed by the American Meteorological Society (AMS) and United States Environmental Protection Agency (US EPA). AERMOD is the US EPA preferred model for regulatory air dispersion modelling of industrial sources and Nova Scotia Environment (NSE) has approved its use in various modelling projects to demonstrate compliance in Nova Scotia.

The air dispersion model simulated the transport of contaminants released from the quarry and compared the predicted concentrations at nearby residences to the applicable limits. The model captures the potential “worse case” operating scenario: Phase 5, which represents peak production and maximum vehicular traffic as well as Phase 3 when generators will be used before the electrical line is constructed. Vessel emissions are also included.

The modelling results demonstrate that even under worse case scenarios, Project-related air contaminants at the nearest residences are far below the maximum acceptable concentrations established by provincial and federal regulation. In particular, the predicted 1-hour and 24-hour maximum, and the annual average concentrations for nitrogen dioxide (NO₂), sulphur dioxide (SO₂), and particulate matter (including TSP, PM₁₀ and PM_{2.5}), as well as the 1-hour and the 8-hour maximum concentrations for carbon monoxide (CO) were found to be at least 50% below their respective objectives.

With respect to GHGs, calculations presented in Sections 3.3.10 (Air Emissions) and 3.3.12 (Emissions to Atmosphere from Marine Operations).

The Canadian National GHG Inventory for the 2012 calendar year shows the carbon dioxide equivalent emission levels for Nova Scotia to be 17,400 kt, of which the mining and oil and gas industrial category generated 201 kt of emissions, a very small proportion. The Project's total GHG emission level at the maximum generation rate during Phase 5 is estimated at 9,464 tonnes per year CO₂e (Sections 3.3.10 - Air Emissions). For comparison, this level would be roughly 0.05% of the Province's total GHG emissions for 2012.

Given these findings, changes to the atmospheric environment resulting from Project activities will not have a measureable effect on federal lands (i.e., the Canso Islands National Historic Site) or on area of federal jurisdiction (i.e., lands currently used by Aboriginal peoples).

7.1.5 Mitigation & Monitoring

7.1.5.1 Mitigation

The mitigation measures used to minimize and control the air pollutants from the construction, operations, and decommissioning activities are outlined in Table 7.1-4. Standard best management practices for air quality mitigation that apply to the entire Project site are:

- Regular maintenance of all equipment and emission control devices;
- Wet sprays on conveyor transfer points to reduce the fugitive releases of dust during the transfer of material;

- The application of water to the access and haul roads and aggregate stockpiles as needed. A water truck will be available on site to transport water where needed;
- Use of qualified blasting contractors with blast design plans that incorporate dust emission controls;
- Construction of the haul roads using material with low silt content;
- Use high quality low sulphur diesel or standard unleaded gasoline for mobile equipment; and
- Use of a binder substance within the dust suppression application (e.g. calcium chloride) during drier periods of the year to aid in keeping the roads moist for longer periods of time.

Additional controls will be implemented through the process of adaptive management. Adaptive management is an iterative process where future actions are taken based on observation and/or measurement. For example, dust generation from haul roads is related to moisture in the roadway and speed of the vehicle. Through adaptive management, the Proponent may learn that immediate dust reductions are possible through limiting vehicle speed so that water trucks can be used less often. The Proponent will use adaptive management to evaluate changing conditions at the operation due to weather such as temperature, wind speed and direction, sun intensity, time since last rain and snow cover as well as operating rates and location of mining activities at the time. This information will allow quarry managers to make decisions on how to adjust dust control techniques (such as rate of water application to haul roads and stock piles), and also modify operational parameters such as production levels and haul truck speeds to ensure dust generation is controlled.

Some of the control measures that will be implemented based on management determination of need include:

- Increase in watering frequency of haul roads and stock piles.
- Application of dust suppressants to the haul and access roads.
- Reduction in allowable speed on haul and access roads.
- Restriction or suspension of operation of part or all of the processing plant until dust can be controlled.
- Suspension or modification of overburden handling activities.
- Addition or modification of dust suppression systems to address specific points where dust is being generated, including spray nozzle additions and/or modifications.
- Modify operation and dust controls during high wind events (>30 km/h) to control dust, if it cannot be controlled suspend operation until it can.

The Proponent will take steps to reduce GHG emissions including purchasing of heavy off-road mining equipment that meet the US EPA and Canadian Tier 4 engine standards, operating mobile equipment with fuel efficiency in mind by eliminating unnecessary idling, shutting off equipment when parked unless this is precluded for safety or maintenance reasons, utilizing conveyors to reduce the need for mobile equipment, and through the use of marine vessels, which are much more energy efficient (and so produce less GHGs) than ground transportation options (Table 3.8).

7.1.5.2 *Monitoring*

Although air quality impacts are expected to be negligible, regular inspection and air quality monitoring (as needed) are typically used to ensure dust emissions are minimized. Additional monitoring programs are outlined on Table 7.1-4. For example:

- Perform daily visible emissions inspection at the property line. If visible emissions are observed or are reported off-site, the operator will investigate the condition and take appropriate corrective actions within the site to reduce dust emissions through measures such as wetting of dust sources with water, use of covers or other approaches. Records of the inspections and excess dust events will be kept, along with corrective actions taken which will be reported as appropriate to government agencies.
- To ensure that public concerns are part of daily management of the site the Proponent will have a telephone number at the site that can be used to report issues that the public may have with the facility, such as dust emissions observed beyond the Property boundary.
- If requested by Nova Scotia Department of Environment, measure Suspended Particulate Matter at the property line of the Project site or other location as directed.
- Monitor weather for conditions that contribute to adverse air quality in the area (e.g. inversions, high winds, dry) and take additional precautions to minimize emissions during these events.
- Monitoring of worker exposure to dust through the regular use of dust dosimeters carried by workers during the course of their shift.

**Table 7.1-4:
Best Practice Mitigation for Air Quality**

Project Activity	Mitigation	Record Keeping and Monitoring
Construction		
Site Preparation	<ul style="list-style-type: none"> • Prior to burning, explore options to reduce, reuse, or recycle as much material as possible. • Limit burning to periods with adequate atmospheric dispersion. • Apply water or chemical dust suppressant on all disturbed areas, as necessary. • Limit the amount of vegetation clearing to the smallest extent possible. • Suspend activities during periods of sustained high winds (> 30 km/h) if fugitive dust emissions cannot be controlled. • Compact the soil on disturbed areas that will not be surfaced with gravel or re-vegetate as soon as practicable following construction. 	<ul style="list-style-type: none"> • Inspect burning pile for material that can be reused or recycled. • Record location and date of burning events. • Perform daily visible emissions inspection and maintain records. • If visible emissions are observed or reported, the operator will investigate the condition and take appropriate corrective actions. • Record hours of operation for the water truck and areas of the facility where water and/or chemical dust suppressants were applied. • Document sustained periods of high wind speeds.
Soil and Aggregate Handling and Storage	<ul style="list-style-type: none"> • Apply water on all disturbed areas, as necessary. • Locate piles in areas sheltered from wind where possible. • Minimize rock drop distances. • Minimize storage and handling of soil/aggregate. • Suspend soil/aggregate handling activities during sustained periods of high winds (> 30 km/h). • Restrict access to soil/aggregate piles during periods of inactivity using gates, fencing, and/or onsite security personnel. 	<ul style="list-style-type: none"> • Perform daily visible emissions inspection and maintain records. If visible emissions are observed or are reported, the operator will investigate the condition and take appropriate corrective actions. • Record the application of water and/or chemical dust suppressant. • Document periods of high wind speeds.
Portable Processing Plant	<ul style="list-style-type: none"> • Ensure efficient operation of dust suppression equipment on portable units. • Minimize drop distances as far as practicable. • Water spray during non-freezing conditions. • Minimize transfers of material. • Suspend activities during periods of sustained high winds (> 30 km/h) if fugitive dust emissions cannot be controlled. 	<ul style="list-style-type: none"> • Maintain a record of equipment maintenance and inspections of dust control equipment. • Document periods of high wind speeds. • As requested by NSE, install monitoring stations to record dust levels.

Project Activity	Mitigation	Record Keeping and Monitoring
Access Road/Haul Roads	<ul style="list-style-type: none"> Utilize multi-passenger vehicles to transport crew when possible. Reduce vehicle speeds. Post speed limit signs in sensitive areas. Apply water or dust suppressants during dry conditions. Restrict traffic during unusually windy times when dust formation is enhanced. Restrict vehicular access during periods of inactivity using gates, fencing, and/or onsite security personnel. Ensure that water trucks are available when needed. 	<ul style="list-style-type: none"> Perform daily visible emissions inspection and maintain records. If visible emissions are observed exceeding opacity limits specified in the permit, or are reported, the operator will investigate the condition and take appropriate corrective actions. Record the application of water and/or chemical dust suppressant. Document location of residences and other sensitive areas.
Engines and Vehicles	<ul style="list-style-type: none"> Maintain equipment regularly following manufacturer guidelines. Maximize equipment use when running and minimize unnecessary idling of equipment. Consider fuel efficiency when purchasing, upgrading, and maintaining the vehicle fleet. Use high quality, ultra-low sulphur diesel fuels or standard unleaded gasoline. Schedule and arrange construction activities to minimize transport time for vehicles and ensure that construction activities are sequenced in a manner to enhance vehicle use. Turn off equipment that is idling and not in use. 	<ul style="list-style-type: none"> Maintain engine certifications for off-road equipment and diesel generators and compare against applicable provincial or national standards. Check maintenance is up to date on each vehicle, equipment, and diesel generator based on the maintenance schedule. Record date of any maintenance, inspections, and tuning of equipment.
Operation		
Drilling and Blasting	<ul style="list-style-type: none"> Utilize drill rig that has dust suppression incorporated into its design. Apply water to shot rock pile as needed to reduce emissions from loading and conveyance of material to the process. Suspend blasting activities during periods of sustained high winds (> 30 km/hr). 	<ul style="list-style-type: none"> Record the number of blasts. Record the application of water. Document periods of sustained high wind speeds. As requested by NSE, install monitoring stations to record dust levels.

Project Activity	Mitigation	Record Keeping and Monitoring
Access and Haul Roads	<ul style="list-style-type: none"> • Same as during construction 	<ul style="list-style-type: none"> • Same as during construction
Permanent Processing Plant	<ul style="list-style-type: none"> • Same as with portable plant 	<ul style="list-style-type: none"> • Same as with portable plant
Storage Piles	<ul style="list-style-type: none"> • Apply water or chemical dust suppressant on stockpiles, as necessary. • Locate piles in areas sheltered from wind where possible 	<ul style="list-style-type: none"> • Perform daily visible emissions inspection and maintain records. If visible emissions are observed or are reported, the operator will investigate the condition and take appropriate corrective actions. • Record the application of water and/or chemical dust suppressant.
Exhaust Emissions from Equipment and Vehicles	<ul style="list-style-type: none"> • Maintain equipment following manufacturer guidelines. • Maximize equipment use when running and minimize unnecessary idling of equipment. • Consider fuel efficiency when purchasing, upgrading, and maintaining the vehicle fleet. • Ensure power generation via diesel generators meet applicable provincial standards. • Use multi-passenger vehicles to transport crew to site to the extent practical. • Use high quality, ultra-low sulphur diesel fuels or standard unleaded gasoline. 	<ul style="list-style-type: none"> • Maintain engine certifications for off-road equipment and diesel generators and compare against applicable provincial standards. • Check maintenance is up to date on each vehicle, equipment, and diesel generator based on the maintenance schedule. • Look for excessive emissions (soot) from vehicle exhaust. • Record date of any maintenance, inspections, and tuning of equipment.
Marine Engines	<ul style="list-style-type: none"> • Ships must comply with International Marine Organization limits on NO_x, VOC, and SO₂. • Optimize load times to limit auxiliary engine idling on ships at dock. 	<ul style="list-style-type: none"> • Record all emission tests/certifications. • Record fuel sulfur content of ships.
Decommissioning		
Decommissioning activities are expected to be comparable to construction activities. Therefore, the same mitigation and monitoring procedures will apply.		

7.1.1 Residual Effects and Significance

The Project is expected to have a minimal adverse residual impact on the local air shed. Table 7.1-5 provides a summary of the residual environmental effects and demonstrates the Project is not likely to have significant adverse effects on Air Quality and Climate Change.

**Table 7.1-5:
Residual Environmental Effects for Air Quality and Climate Change**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect

Decommissioning

Decommissioning activities are expected to be comparable to construction activities. Therefore, the same analyses apply. Not Signif.

Legend

Magnitude:

U = Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.
0 = Nil - No environmental effect.
1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)
2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)
3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)

Geographic Extent:

1 = < 1 km²
2 = 1 – 10 km²
3 = 11 – 100 km²
4 = 101 – 1,000 km²
5 = 1,001 – 10,000 km²
Duration:
1 = < 1 month
2 = 1 – 12 months
3 = 13 – 36 months
4 = 37 – 72 months
5 = > 72 months

Frequency:

1 = < 11 events/year
2 = 11 – 50 events/year
3 = 51 – 100 events/year
4 = 101 – 200 events/year
5 = > 200 events/year
6 = continuous

Reversibility:

R = Reversible
I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.
2 = Evidence of adverse environmental effects.
N/A = Not applicable
A = Adverse
P = Positive

7.2 NOISE AND VIBRATION

7.2.1 Overview

Activities such as blasting and aggregate processing will undoubtedly produce noise and have the potential to alter the ambient noise conditions of the local area. Noise concerns have been raised by residents living to the east and west of the property. Changes to ambient noise may also affect a variety of wildlife, migratory birds and SAR through driving them out of the area and/or other effects on their behaviour. Noise associated with quarry activities is regulated by the Province of Nova Scotia.

Construction of the marine terminal will likely result in temporary increases to noise in the marine environment, which may in turn affect nearby marine biota. Noise may alter the behaviour patterns of certain marine species, which may in turn affect these species at different times of their life cycles. Shipping associated with the marine terminal will add to the noise already present in the marine environment.

7.2.2 Boundaries

7.2.2.1 Temporal Boundaries

Temporal boundaries reflect the duration of Project-related impacts. With respect to Noise and Vibration, the temporal boundaries are:

- Construction (Phase 1)
 - Establish access and haul roads, site preparation: 3 years (2017-2020)
 - Establish portable processing plant (Phase 1): 1 year (2017-2018)
- Operation (Phases 2-5)
 - Establish portable processing plant (Phase 2): 2 year (2018-2020)
 - Construction of marine terminal: 1 year (2019-2020)
 - Expansion of portable processing plant (Phase 3): 2 years (2020-2022)
 - Construction of fixed processing plant (Phase 4): 1 year (2021-2022)
 - Expansion of fixed processing plant (Phases 5): 4 years (2026-2030)
 - Operation of access and haul roads, marine terminal, quarry: end of construction to end of life (~2065)
- Closure, decommissioning, and final reclamation: estimated at 2 years but may be extended.

Daytime, evening and night time periods, described below, are also considered temporal boundaries for the purposes of the noise and vibration assessment.

7.2.2.2 Spatial Boundaries

The spatial boundaries for the noise and vibration assessment consist of the Project Area (within the Project property boundary where workplace health and safety regulations dominate), the Affected Area extending to nearby residential properties where provincial noise limits must be met, and the larger Study Area, including the shipping routes between the marine terminal and established shipping lanes, where more diffuse Project impacts may be expected.

7.2.2.3 Administrative Boundaries

Noise within the Project site is regulated by the province through the *Workplace Health and Safety Regulations*, which establishes the noise environment needed to maintain worker health. The *Pit and Quarry Guidelines* (NSE 1999) require that noise levels at the boundaries of the project site are not to exceed the following levels:

- $L_{eq} \leq 65$ dBA between 0700 to 1900 hours (daytime)
- $L_{eq} \leq 60$ dBA between 1900 to 2300 hours (evening)
- $L_{eq} \leq 55$ dBA between 2300 to 0700 hours (night-time, Sunday and statutory holidays)

The *Guidelines for Environmental Noise Measurement and Assessment* (NSE 1990) also require these noise levels to be met at locations where people normally live, work, or take part in recreation.

7.2.2.4 Technical Boundaries

No technical boundaries are defined for noise.

7.2.3 Threshold for Determination of Significance

A significant adverse effect is defined as an exceedance of the maximum noise or vibration limits listed in the *Pit and Quarry Guidelines* at or beyond the property boundary, where the exceedance is due to noise from the operation and the event occurs more than twice in the period of time that the standard is based.

7.2.4 Effects of the Project on Noise

Project noise and vibration effects were considered in the following potential areas:

- Construction noise and vibration, both terrestrial and underwater;
- Noise from on-going aggregate production and shiploading operations; and
- Noise and vibration from blasting, including impacts on people and structures and the potential for underwater impacts on wildlife.

This assessment also identifies the potential *perceived* noise and vibration effects from the Project, since impacts on people may exist even if compliance with numerical noise and vibration criteria is achieved.

This section summarizes the noise and vibration impacts of the Project. More detail is contained in the Noise and Vibration Technical Report attached as **Appendix D** to this EIS.

7.2.4.1 Project Construction Noise and Vibration Impacts

The site development and initial rock processing during the construction phase of the Black Point operation will involve activities similar to those that will occur during full facility operation. Equipment used for the construction will be similar to that used for site operation. Noise generated during construction is anticipated to be similar to or less than the noise generated from facility operations; however, the duration of noise during construction will be less than the fully operational quarry.

For example, the number of heavy vehicles accessing the quarry site by road may be higher during some periods of construction than during operations. Trucks will be used to transport processing equipment to the site and this activity will cease before full operations begin. Increased heavy vehicle noise on local roads may be noticeable at times during construction, but this is expected to be temporary and will be confined to normal working hours.

The construction of the marine terminal has the potential to affect marine receptors including marine mammals due to underwater noise and vibrations produced during construction. These effects would be temporary and localised to the immediate construction area. It is estimated that the underwater noise criteria applicable to fish habitats (including shellfish and crustaceans) may be exceeded during pile driving in an area around the pile locations extending seaward up to 10 m (**Appendix D**). Behavioural modification may occur at greater distances, for the duration of the construction.

7.2.4.2 Project Operational Noise Impacts

The Black Point operation will generate noise from the operation of mobile equipment, the operation of the processing plant, blasting and product loadout at the marine terminal. As noted above, the *Pit and Quarry Guidelines* (NSE 1999) require that noise levels at the boundaries of the project site are not to exceed the following levels:

- $L_{eq} \leq 65$ dBA between 0700 to 1900 hours (daytime)
- $L_{eq} \leq 60$ dBA between 1900 to 2300 hours (evening)
- $L_{eq} \leq 55$ dBA between 2300 to 0700 hours (night-time, Sunday and statutory holidays)

The *Guidelines for Environmental Noise Measurement and Assessment* (NSE 1990) also require these noise levels to be met at locations where people normally live, work, or take part in recreation.

In order to calculate the noise emission levels at the site boundary and at residential receiver locations an environmental computer model was developed using SoundPLAN. This software enables compilation of a sophisticated computer model comprising a digitised ground map, the location and acoustic sound power levels of potentially critical noise sources on site and the location of receivers for assessment purposes.

The noise model developed is representative of a “worst-case” scenario for noise impacts. As the detailed design is not yet completed, a number of assumptions have been made in order to predict the maximum potential for operational noise impacts and need to consider noise mitigation:

- Impacts are predicted for a future operational scenario, with all equipment operating at the maximum anticipated capacity.
- The pit has been modelled as expanded to its maximum size, when it will provide a minimum of shielding effect.
- The model assumes all noise sources and equipment are operational continuously throughout a daily production schedule of 16 hours, with a maintenance schedule of 8 hours.
- Shiploading is modelled as occurring continuously at all times of the day or night, when in fact this would be expected to occur on less than a third of all days or nights.

- Downwind sound propagation has been assumed – under calm conditions, noise would propagate less.
- Hard ground (bedrock) was assumed across the Project site and over the ocean, with soft ground (soil and surficial deposits) to the east, west and south.
- Equipment sound power levels have been derived from SLR's experience of the unmitigated noise emissions of equipment in similar applications. The source levels assumed are considered to be conservative. There is potential to mitigate the noise emissions of equipment during the detail design of the Project to minimise noise impacts.

The predicted worst-case, unmitigated noise effects in the future operational scenario are summarised in Table 7.2-1 at the site boundary and in Table 7.2-2 at residential receiver locations.

**Table 7.2-1:
Predicted Worst Case Project Noise Levels – Site Boundary**

Location	Leq Sound Level (dBA)	
	Daytime and Evening (7am to 11pm)	Night-time (11pm to 7am)
Western Boundary	66-67	47-57
Southern Boundary	47-64	29-39
Eastern Boundary	56-73	34-58

Maximum permitted at nearest residence: 65 dBA daytime / 60 dBA evening / 55 dBA night-time

235 Fox Island Main Rd	48	34
RR 1 Canso	50	35

Maximum permitted at nearest residence: 65 dBA daytime / 60 dBA evening / 55 dBA night-time

7.2.4.3 Daytime and Evening Noise Impacts on Residences

Under the worst case scenario, the predicted noise levels at the nearest residences during the daytime and evening range from 47 dBA to 55 dBA, complying with the most stringent noise limit of 55 dBA. At the commencement of quarry construction and operation, noise levels would be expected to be considerably less than indicated in this assessment.

While compliance with the numeric noise limits at residences is expected, the noise of the quarry will be noticeable at residences during the daytime and evening, particularly during otherwise quiet periods. Quarry production noise is generally characterised by low-frequency “rumbling” noise that does not vary much with time. At the levels predicted in this assessment, it is anticipated that noise from the quarry would dominate the background noise environment in the local area during the daytime and evening periods, and will be audible at a “moderate to quiet” level in nearby residential areas.

7.2.4.4 Night-time Noise Impacts on Residences

The predicted noise levels at the nearest residences during night-time shiploading and site maintenance activities range from 25 dBA to 41 dBA, complying with the night-time limit of 55 dBA. Shiploading is expected to occur on around 100 nights per year once operations reach full capacity.

While compliance with the numeric night-time noise limits at residences is expected, the noise impact of night-time shiploading will be noticeable at nearby residences. At the levels predicted in this assessment, it is anticipated that noise from night-time shiploading would contribute to the background noise environment in the local area, and will be audible at a “quiet” level in nearby residential areas during calm weather. The character of night-time noise would be a steady low-frequency “rumbling” noise. The night-time noise level would not be expected to disturb the sleep of most people in the long term.

7.2.4.5 Noise Impacts at Project Boundary

The predicted noise levels around the project boundary indicate there is potential for exceedances of the noise goals at the project boundary both during daytime operations and during night-time shiploading and site maintenance activities. These predicted noise impacts represent a worst-case scenario with no noise mitigation measures included in the detailed

design. The highest noise levels are predicted at the boundary on the coast both to the east and to the west of the site – this is because these project boundaries are closest to the dominant production equipment noise sources, and do not benefit from as much shielding by the terrain as the areas south of the site.

7.2.4.6 Blasting Noise and Vibration Impacts

Blasting will occur anywhere from 30 to 120 days per year, depending on aggregate sales demand. The Pit and Quarry Guidelines (NSE 1999) define acceptable limits for blast overpressure (noise) and vibration, and also require a minimum distance from blasting to the nearest off-site structure greater than 800 m. Minimum blasting distances are respected in all directions from the Property boundary.

The assessment indicates that exceedance of the airblast overpressure limit and vibration limit at sensitive receivers is unlikely throughout the life of the quarry.

While underwater blasting is not anticipated to be required by the Project, the location of the quarry adjacent to the ocean means that there is potential for quarry blasting noise and vibration to impact on the underwater environment and marine fauna. Blasting effects in the marine environment are described in Section 7.11.

7.2.5 Mitigation & Monitoring

7.2.5.1 Mitigation

As noted, there is potential for exceedances of the noise limits at the project boundary both during daytime operations and during night-time shiploading and site maintenance activities. These predicted noise impacts represent a worst-case scenario with no noise mitigation measures included in the detailed design. As required by the Pit and Quarry Guidelines (NSEL 1999) a Technical Blast Design must be prepared before blasting begins. The blast design must demonstrate the concussion and ground vibration criteria in the Pit and Quarry Guidelines can be met within the site.

There is considerable opportunity to reduce the effects from noise below the levels described in the tables above by design and implementation of noise mitigation measures. Reasonable and feasible mitigation options include the procurement of equipment that meets best practices in terms of noise emissions, and the placement of equipment within the quarry and/or behind stockpiles such that these measures block noise during operations. More generally, the following noise mitigation measures (NSW 2008) will be evaluated during the final design phase and later when construction and operation are beginning.

General

- Procure equipment that meets US EPA Category IV air emission standards for off-road diesel equipment which tend to generate less noise than older equipment;
- Equipment that operates in the quarry pit should stay in the pit to the extent possible so that the pit walls attenuate the noise levels;
- Locate product stockpiles and other structures such as buildings and conveyors to the extent possible to attenuate the noise from the processing equipment;

- Restrict operating hours for the quarry and processing plants to 16-hours per day so that noise levels are reduced during night time;
- Restrict blasting to daytime hours and weekdays;
- Place as much distance as possible between the plant or equipment and residences;;
- Use natural landforms as noise barriers. Place fixed equipment behind earth berms;
- Include clauses in tenders, subcontractor agreements and work method statements that assure the minimization of noise and compliance with directions from management to minimize noise;
- Regularly train workers and contractors (such as at toolbox talks) to use equipment in ways that minimize noise;
- Ensure that site managers periodically check the site, nearby residences and other sensitive receptors for noise problems so that solutions can be quickly applied;
- Keep truck drivers informed of designated vehicle routes, parking locations, acceptable delivery hours and other relevant practices (e.g. minimizing the use of engine brakes and engine idling); and
- Minimize the use of reversing alarms by designing the site layout to avoid reversing, such as by including drive-through for parking and deliveries.
- Ensure the site office is manned 24 hours per day so that complaints can be logged and follow up responses initiated.

Night-time Mitigation Measures

- Minimize the need for reversing alarms; and
- Avoid metal-to-metal contact on equipment.

The Community Liaison Committee will also provide a forum to discuss issues such as quarry and ship loading noise and offer opportunities to find innovative solutions to local concerns. A noise notification procedure will be discussed and, if found to be warranted, implanted at the site. Such a procedure may include for example:

- Provide information/advance notification to neighbors before and during construction through media such as letterbox drops or meetings;
- Defining activities that are expected to be noisy and their expected duration, what noise mitigation measures are being applied, and when noise respite periods will occur; and
- Upon request, residents will be alerted to upcoming production shots (blasts) via automated telephone notifications ("robo-calls").

7.2.5.2 Monitoring

The staged development of the quarry means that there is scope to monitor noise emissions as the quarry expands and to include additional noise mitigation in the later stages if required to comply with the noise limits at the site boundary.

As required by the NSE Pit and Quarry Guidelines, all blasts will be monitored to ensure overpressure and vibration levels remain within maximum acceptable limits. This monitoring would be used to develop site-specific propagation constants to enable refinement of the blast overpressure and vibration predictions as the quarry develops. In this manner, blast designs can be adopted that comply with the overpressure and vibration limits at sensitive receivers throughout the life of the quarry.

As part of the workplace health and safety program, noise monitors will be attached to workers on a regular basis to measure and monitor noise exposure over an eight hour shift.

At the request of NSE, additional noise monitoring may be undertaken during daytime, evening and night-time during the early operational phase to verify compliance with regulatory guidelines. Methodologies will follow those described in the Nova Scotia Department of Environment and Labour Guidelines for Environmental Noise Measurement and Assessment (NSEL 1990).

The Noise and Vibration Technical Report (**Appendix D**) identifies indicative offset distances between a blast and the ocean to meet the underwater noise and vibration limits defined in Guidelines for the Use of Explosives In or Near Canadian Fisheries Waters (Wright and Hopky 1998). These indicative setback distances will be refined following monitoring of initial test blasts at the site. Depending on their proximity to ocean habitats, these initial blasts may need to be designed to limit their intensity. Initial blasts would identify the site-specific vibration transmission characteristics to enable blast design to comply with the underwater noise and vibration limits.

The Project is expected to have a low adverse residual impact on ambient noise. Table 7.2-3 provides a summary of the residual environmental effects and demonstrates the Project is not likely to have significant adverse effects on Noise and Vibration.

**Table 7.2-3:
Residual Environmental Effects for Noise**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Construction									
Site Preparation, Trucking	A	See Mitigation Section	1	2	3/3	R	1	Increased ambient noise	Not Signif.
Operation of the Temporary Processing Plant	A	See Mitigation Section	1	2	3/6	R	1	Increased ambient noise	Not Signif.

4 = 101 – 200 events/year
5 = > 200 events/year
6 = continuous

Reversibility:

R = Reversible
I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.
2 = Evidence of adverse environmental effects.
N/A = Not applicable
A = Adverse
P = Positive

7.3 AMBIENT LIGHT

Ambient light was identified in the EIS Guidelines as a potential VC. The Project site is currently undeveloped and night time ambient light conditions are low. As the site is developed into a quarry, artificial light will be introduced in the form of vehicle headlights, work area illumination lighting, and lights installed on the marine terminal to ensure safe navigation. Changes to ambient light conditions have the potential to negatively affect wildlife, including birds from the immediate area as well as those birds from much further away. Increases in night time light levels may also be perceived as a nuisance by local residents.

The lighting design for the quarry has not yet been completed but it is possible to make assumptions about the location and intensity of the site lighting. Site lighting will consider the following:

- Safety of those working on the site;
- Government regulations and design standards;
- Equipment and layouts that minimise the impact of new lighting on the surrounding environment; and
- Equipment and layouts that maximise the efficiency of the lighting system.

Details of ambient light existing conditions on the Project site are presented in Section 6.3.

7.3.1 *Boundaries*

7.3.1.1 *Temporal Boundaries*

The temporal boundaries for the assessment of impacts upon ambient light begin at the construction phase and continue through the operational phase, ending with the final decommissioning of the quarry. Construction time is estimated at three years, quarry operations are expected to continue for at least 50 years and closure and decommissioning is expected to require an additional two years but may be extended if needed.

7.3.1.2 *Spatial Boundaries*

The spatial boundaries for the assessment of this VC include the Project footprint, adjacent lands to the east and west (the Affected Area - up to and including residents along Half Island Cove and in Fox Island Main) and Chedabucto Bay south of the established shipping lanes.

7.3.1.3 *Technical Boundaries*

Under the Canada Labour Code, the minimum illumination levels required at various workplace locations are directed by the *Canada Occupational Health and Safety Regulations* (SOR/86-304). To the extent that migrating birds may be affected by the Project, the federal *Migratory Birds Convention Act 1994* and the *Species at Risk Act* are applicable.

7.3.1.4 *Administrative Boundaries*

No administrative boundaries were identified for the Ambient Light VC.

7.3.2 Threshold for Determination of Significance

On human receptors the adverse effects of light trespass are due both to an increase in general illuminance that may cause annoyance and may disrupt sleeping patterns, and from the direct view of the light source that can cause glare issues. The adverse effects of light trespass from exterior lighting are influenced by a number of factors:

- The topology of the area. Light trespass is more likely to be perceived as obtrusive if the lighting installation is located above the observer. Lighting installations are usually directed towards the ground and an observer could hence have a direct view of the luminaire.
- The surrounding topography and existing installations. Hills, trees, buildings, fences and vegetation generally have a positive effect by shielding the observer from the light source.
- Pre-existing lighting in the area. Light from a particular light source is seen as less obtrusive if it is located in, or perceived in, an area where the lighting levels are already high, e.g. along roads and near built up areas. .
- The zoning of the area. A residential area is seen as more sensitive compared to commercial areas where high lighting levels are seen as more acceptable.
- Time of use. Clearly light will be seen as being more obtrusive during night time. This is generally considered to be between 11:00pm and sunrise.

A significant impact is defined as direct light trespass that according to the affected resident regularly interferes with the use and enjoyment of nearby residential properties on a permanent basis and/or evidence of unacceptable levels of bird mortality associated with Project lighting (unacceptable levels are defined in Section 7.3.5.1).

7.3.3 Effects of the Project of Ambient Light

7.3.3.1 Construction

With the installation of safety lighting, ambient light levels will increase during the construction of the processing plant, associated infrastructure and the marine terminal. Other lighting introduced to the site will come from vehicle headlights moving around the site as well as entering and exiting the site at the intersection with Route 16.

Temporary lighting systems (including portable lights) may be used during construction to illuminate specific areas and ensure the safety of staff.

As vehicles enter and exit the site, vehicle head lights could be aimed in directions other than on the road. The intersection of Route 16 and the quarry access road is approximately halfway between the nearest residences to the east and west. The vegetation at the sides of the road in this area is quite dense so there should be no light trespass from headlights onto the closest buildings.

7.3.3.2 Operation

Potential Effects on Residents

In addition to permanent safety lighting and vehicular headlights, ambient light levels will increase during the operation of stockpiles, load-out facility and marine terminal.

The following areas will require new lighting as part of the operational phase of the Project. Included is the minimum illumination required for those areas (taken from the Canada Occupational Health and Safety Regulations (SOR/86-304), Section 6.11).

1. Marine terminal – an illumination of 150 lux⁴ is required.
2. Crusher and processing areas – an illumination of 100 lux is required for the immediate area and 50 lux in the nearby surrounding area.
3. Other work areas – While not specifically referred to in the regulations it is likely that these areas will require at least 200-500 lux depending on how each work area is defined.
4. Site Offices – Offices should have an illumination of 100 lux around the exterior of any entrances and 50 lux around other exterior areas.
5. Roadways – These require 20 lux in high activity areas and 10 lux in low activity areas.
6. Storage areas - These require 30 lux in high activity areas and 10 lux in low activity areas.
7. Parking – Open parking areas should have an illumination of at least 10 lux.

The processing plant and stockpiles will be built on the northern side of the site near the coast at 22 metres above sea level (masl). From here, the quarry will be excavated south towards Route 16. Between the lower coastal platform hosting the processing plant and Route 16, the ground rises to 50 masl and to maximum of about 95 masl. This will provide significant shielding from the east southeast clockwise around to the west southwest and should mean that there will be no significant light trespass on any buildings along Route 16.

There are some buildings along the coast that may have direct line of sight to the marine terminal and, to a lesser degree, main work area. From the west (Yellow Rocks/Half Island Cove Road), the topography prevents direct line of sight view to the quarry, processing plant and marine terminal, except for viewers standing directly on the coast and those who may look toward Black Point from the east side of Gaulman Point. From these vantage points, the marine terminal and stockpiles will be visible, but the quarry will be largely concealed behind a vegetated coastal buffer. Lower Half Island Cove Beach on the east side of Gaulman Point is about 2.9 km from the marine terminal.

There are two topographic ridges between the Property boundary and the houses along Half Island Cove Road. These ridges block direct views from these houses to all work areas. The nearest residence (an abandoned trailer currently for sale) is located approximately 750 m from the property boundary and over 900 m from work areas.

⁴ Lux is the SI unit of luminance and luminous emittance as perceived by the human eye.

To the east, direct line of sight viewers are located on the east side of Indian Cove along Fox Island Cove Road. Black Point can also be seen from the beach at Indian Cove, located 3.5 km east of the proposed processing plant. From this direction, much of the processing plant, quarry and marine terminal is expected to be shielded from view by Black Point itself (which is not part of the quarry property and which will remain forested), as well as a 30 m wide vegetated buffer left along the coast. It is likely the tallest components of the processing plant (conveyers, tops of stockpiles, and lighting fixtures) may be visible from these eastern viewpoints.

Potential Effects on Fauna

Reflected light is used by animals to collect a wide range of information within their environment. At night, many nocturnal animals use moonlight and starlight to forage for food and detect predators. Objects in the night sky may be used as aids to navigation for migrating birds. Patterns of light and darkness are also used to regulate circadian cycles; to control the behavior of diurnal, nocturnal and crepuscular animals⁵; to determine day length; and as a directional cue for navigation (Gaston *et al.* 2012).

Lighting needed to illuminate working areas and for navigational purposes at the marine terminal can have an adverse effect on migrating birds. Under conditions of poor visibility, nocturnal migrating birds may be attracted to bright lights. Under cloudy or foggy conditions water droplets in the air refract light creating an illuminated area around the lights. Birds that have lost their celestial navigation aids may enter these illuminated areas and become confused possibly resulting in collisions, exhaustion and mortality (JWEL 2004). Environment Canada has noted that in Atlantic Canada, nocturnal migrants and night-flying seabirds (e.g. storm-petrels) are the birds most at risk of attraction to lights. Attraction to lights may result in collision with lit structures or their support structures, or with other birds. Disoriented birds are prone to circling a light source and may deplete their energy reserves and either die of exhaustion or drop to the ground where they are at risk of depredation.

Strong unidirectional or rotating light sources are most likely to create this problem. Flood lights are associated with bird mortality since the strong lighting attracts birds close to the lighted structure where collisions occur. Navigational beacons may also affect birds since this lighting is typically positioned at heights where night migrating birds are more likely to encounter them. Solid or pulsing red navigation beacons have the strongest ability to attract birds while slow strobe lights have the weakest ability (JWEL 2004).

Decreasing the duration of lighting may alleviate some but not all impacts on nocturnal and crepuscular animals, since peak lighting demand periods often coincide with the peak activities of these species (Gaston *et al.* 2012). Reducing lighting trespass will maintain shadows in otherwise well-lit areas, providing dark refuges that animals can make use of. Decreasing lighting intensity will limit both skyglow (thus reducing the risk to migrating birds) and reduce the surface area impacted by high-intensity direct light. Lowering light intensity also reduces the trespass of reflected light into otherwise unlit areas. Flexible lighting control systems can also be used to mitigate ecological impacts by providing dark periods of sufficient duration for normal ecological function (Gaston *et al.* 2012).

⁵ Diurnal animals are most active during the day; nocturnal animals are most active at night; crepuscular animals are most active at dusk and dawn.

7.3.3.3 Decommissioning

The effects on ambient light during the decommissioning phase of the Project are anticipated to be similar to construction.

7.3.4 Mitigation and Monitoring

The lighting design will aim to mitigate light trespass from the site and minimise the increase in ambient lighting. At this early development stage mitigation techniques are relatively easy to incorporate into equipment design and work area layouts. In order to achieve the best performance outcome for the quarry while having a minimal impact on the surrounding environment both general and site specific mitigation measures are described.

7.3.4.1 General Mitigation

The following general mitigation methods can be incorporated into the detail design to minimise adverse effects of the lighting installations.

- Use luminaires that are aimed to minimise light trespass, e.g. full cut off luminaires where no light is emitted above the horizontal plane (where their use does not compromise worker safety). Less trespass light means that more of the light output can be used to illuminate the area and a lower power output can be used. The energy consumption for the fitting can thus be reduced without decreasing the illuminance of the area (**Figure 7.3-1**).

Figure 7.3-1:
Minimise Light Trespass

- Do not waste energy and increase light pollution by over-lighting; use only the lights needed to meet local lighting objectives.
- Keep glare to a minimum by keeping the main beam angle less than 70° , where practical (**Figure 7.3-2**).

Figure 7.3-2:
Minimise Glare

- Use floodlights with asymmetric beams where possible.
- Direct the site lighting away from sensitive locations such as residential properties.
- Where possible position lights as far away from site boundaries as practical.

7.3.5 Site Specific Mitigation

Bird collisions with Project lighting and subsequent mortality are expected to be rare but if it occurs, it would not likely have significant effects on migrating bird populations. Even so, efforts will be made to reduce the effect of lighting on migrating birds. Lighting requirements at the marine terminal will be more fully defined at later stages in the Project design. Where possible, lighting will be kept at low heights to reduce the chance of illuminating migrating birds as they pass through the area. Pole mounted lighting will be pointed downward and shielded from the top and sides. To the extent possible, low intensity lighting will be used rather than high intensity lighting.

In an effort to minimise the light trespass from the site and the increase in ambient light, the following mitigation measures will be employed where warranted and where their use does not compromise worker safety:

- As noted above, all lighting will be aimed down as much as possible and light sources will be shielded to prevent light escaping above the horizontal plane (known as full cut off luminaires). Lights will also be kept as close to the required area as possible.
- Lights placed on the outside of the quarry work areas will be kept as low as possible and correctly aimed to prevent lighting areas where it is not needed.
- Lights for the marine terminal will be chosen and aimed to prevent where possible light shining directly into the water. Marine terminal lighting will be controlled so that minimal lighting will be used when the terminal is not in operation.
- If lighting is required at the perimeter of the site it will be aimed inward to prevent off site light trespass. Full cut off luminaires will be considered to reduce and prevent off site light trespass.
- Temporary lighting used during construction will be focussed on the intended work area and will be shielded to minimize spillage.
- To reduce night time ambient lighting effects, operations will be routinely monitored so that lighting can be switched off by work area when it is not needed.
- Consideration will be given to using light sources such as directional LEDs to give a better spread of lighting and reduce the overall intensity of the lighting systems.
- The emission spectrums of light sources can vary depending on the bulb type; certain lights can have a greater effect on some species of wildlife. Consideration will be given to selecting lights that have a lesser effect on the wildlife to help reduce lighting effects on nocturnal species.

7.3.5.1 Monitoring

Should complaints regarding Project lighting be received at the site office, monitoring of site activity will be undertaken to allow for reduction of light levels in non-active work areas, and/or redirection of lighting installation. In addition to the Complaints / Response Protocol established at the site office, the CLC will provide a forum to register concerns and discuss them with Project representatives.

Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified.

The Environmental Management Plan will include instructions on implementing the protocol “*Best practices for stranded birds encountered offshore Atlantic Canada*” (EC 2014e) for responding to avian strandings related to activities in the marine environment. It is noted that a permit is required to implement this type of protocol; prior to proposed activities, the proponent will contact EC-CWS (email: Permi.atl@ec.gc.ca) to obtain a permit application form.

In the event of the mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds, EC-CWS will be notified within 24 hours. Notification will include specific details about the event, including the name and location of the facility, number and species of birds affected, meteorological conditions during the previous night(s), status of lights/flares, and details of any other factor which may have influenced the event. If significant lighting-related bird fatalities are recorded, EC-CWS will be consulted to discuss additional mitigation measures.

7.3.6 Residual Effects and Significance

The ambient lighting on the site will be increased during the construction and operation of the quarry. This may be noticeable at first since the site is currently undeveloped and the only ambient lighting is of natural origin. Increases in ambient light levels and associated effects of light increases on nearby residents and wildlife can be minimized through effective lighting design and lighting layout, combined with ongoing monitoring of site activity to allow for reduction of light levels in non-active work areas when needed.

It is unlikely that surrounding properties and buildings will experience significant adverse effects due to light trespass from the site or vehicle headlights entering and exiting the site. This is largely due to the distance between the properties and the site as well as shielding from the local vegetation and natural topographic and landscape features.

The result of the effects assessment for the ambient light VC is provided in Table 7.3-1: the Project is not likely to have significant adverse effects on Ambient Light.

**Table 7.3-1:
Residual Environmental Effects for Ambient Light**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect

7.4 GEOLOGY, SOIL AND SEDIMENT QUALITY

7.4.1 Overview

There is no evidence to suggest that contaminated soils or sediment are present on the site. Geology, Soil and Sediment quality was identified as a VC primarily due to the anticipated disturbance of potentially acid generating rock, as well as concerns expressed by fishermen with respect to the discharge of sediment-laden water from the Project site and the consequent effects on lobster and their habitat. Sediment quality is described here while marine water quality is described in Section 7.6 and effects on marine species in Section 7.11.

7.4.2 Boundaries

7.4.2.1 Temporal Boundaries

With respect to the disturbance of potentially acid generating rock, Project-related effects to Geology, Soil and Sediments may occur during the construction phase when this rock is originally exposed, and the during the early operations phase until the rock stabilizes in an oxygenated environment. With respect to potential discharge of sediment-laden water (and by extension, to offshore sediment quality), potential Project-related impacts may occur during construction, operation and decommissioning.

7.4.2.2 Spatial Boundaries

Project-related effects are not expected within the Project Area (i.e., within the Property boundary) but may be observed in the marine environment immediately offshore (the Affected Area). The extent of the Affected Area is defined by the zone within the marine environment where elevated concentrations of acidified surface water and/or suspended sediment may be measured above background values, or in the case of suspended sediments, above values that are typically observed during storms and other high wave events.

7.4.2.3 Administrative Boundaries

In Nova Scotia, activities that may result in acid rock drainage, as well as the management of excavated acid generating rock itself, are regulated by the *Sulphide Bearing Materials Disposal Regulations*. Additional guidance is provided in Guidelines for Development on Slates in Nova Scotia (NSE and EC 1991).

There are no marine sediment quality criteria as such. Maximum values for total suspended solids in water in the marine environment are provided in the CCME (1999) Water Quality Guidelines for the Protection of Aquatic Life (Marine). The Nova Scotia Pit and Quarry Guidelines also provide liquid effluent discharge criteria for suspended solids (NSEL 1999). Please see Section 7.6 for a full description of these criteria and their applicability to the Black Point Project.

7.4.2.4 Technical Boundaries

Although a number of rock samples from the Project site have been analyzed for sulphur content to determine acid generating potential (Appendix B), a sampling program as outlined in

the *Sulphide Bearing Materials Disposal Regulations* has not been completed due to difficulty in accessing the coastal area of this undeveloped property. Additional sampling and geotechnical study is planned once access is available, as described below. For the purposes of this assessment, it is assumed that the Halifax Formation rocks are potentially acid-generating and thus will require appropriate management.

Given anticipated results of the topographic modifications on surface drainage patterns described below, no sediment dispersion modeling in the marine environment was deemed necessary to predict environmental effects on marine sediment quality.

7.4.3 Threshold for Determination of Significance

Rocks that exhibit total sulphide content in excess of 0.4%, and which lack other minerals that can neutralize acidity as measured through chemical analysis, are considered potentially acid generating. A significant effect would be an accidental release of low pH, acid rock drainage (pH <4.5) to the marine environment.

With respect to sediment quality, a significant effect would be an accidental release of total suspended solids in excess of the maximum values listed in the CCME (1999) Water Quality Guidelines for the Protection of Aquatic Life (Marine) and/or the Nova Scotia Pit and Quarry Guidelines (NSEL 1999).

7.4.4 Effects of the Project on Geology, Soil and Sediment Quality

The granite rock that will be quarried for aggregate is not acid generating. In contrast, Halifax Formation sedimentary rocks that underlay a small portion of the site (approximately 11.8 of 28.2 ha, see Figure 3.0-26) near the coast may generate acid and/or leach metals when exposed to oxygen. Excavation of Halifax Formation rocks will be required in preparation for the installation of the processing plant and aggregate stockpiles. Five of the six surface samples of rocks collected in the coastal zone and analyzed in 2011 had a sulphide content below the 0.4% threshold. One sample had a sulphide content above the threshold (i.e., 0.935%); however, the material was found to contain some neutralizing capacity with a pH of 7.4. At this time, it is assumed that disturbance of this rock may leach metals and/or generate acid, which if allowed to drain naturally to the marine environment, may negatively affect water quality in the local area. Despite this, the disturbed surface area will be relatively small (i.e., 11.8 ha). Surface water runoff will be collected in stormwater ponds where it will be retained for use as wash water and further diluted by precipitation, runoff from non-acid generating areas, and runoff from non-disturbed areas. Given this, water in the stormwater ponds is not expected to be acidic or contain metals. In the event an accidental release to the marine environment occurs, rapid dilution in the nearshore will result and so no significant effects to marine water quality or biota are expected.

As noted, sedimentation in the marine environment has been identified by fishermen and nearby coastal residents as a potential concern, since the discharge or runoff of sediment-laden water during construction and operation may have harmful effects on nearby lobster habitat or lobster life stages. In addition, residents and fishermen have expressed concern regarding the transport of suspended sediment along the shore and into neighbouring bays.

Only a small portion of ground cover on the coastal platform will be disturbed during initial construction (20.7 ha – **Figure 3.0-26**). This limited disturbance, combined with the

maintenance of a 30 m wide buffer at the coast and the use of standard construction erosion and control measures will help prevent sediment laden runoff from entering the marine environment. More importantly, during the ground preparation for the processing plant and product storage areas the ground surface will be contoured so that storm water runoff and process water used to wash the aggregate will flow back into the property and be collected in sumps or impoundments. Based on this design significant effects to the marine environment are not anticipated.

There is a risk of small amounts of aggregate spillage during the transfer of material from the terminal onto the ships. This is not anticipated to have significant effects on the marine environment since the aggregate is washed to remove fine rock fractions, thus minimizing the sediment that would be released to the environment in the event of a spill. The material that would be released during a spill will consist of granite, a rock type common in the area.

7.4.5 Mitigation & Monitoring

7.4.5.1 Mitigation

A geotechnical drilling and sampling program will be required for the detailed design of processing plant foundations. The sampling program will define areas that contain rocks that are potentially acid generating when excavated. Standard mitigation measures used to manage acid generating rock will be applied. This will include controlling and containing drainage, and managing excavated rock to prevent further oxidation. This may include placing the excavated rock underwater to prevent oxidation and acid generation. This option will be explored with NSE and DFO if additional sampling and analysis demonstrates the presence of significant volumes of acid generating rock.

These mitigation and control measures will be described in the site-specific Environmental Management Plan. The Environmental Management Plan will also describe standard construction best management practices and will include Erosion and Sediment Control Plan and a Stormwater Management Plan to describe erosion control measures and surface water collection and control at the site.

Initial site preparation activities require the construction of stormwater management ponds and a protective berm along coast, inside a 30 m undisturbed coastal buffer. This is followed by contouring and sloping of the processing plant/stockpile area (i.e., the entire coastal platform, excluding a 30 m coastal buffer) so that surface water flows south to settling ponds rather than north to Chedabucto Bay. Once quarry expansion begins in a southerly direction, a sump pit will be excavated to collect water within the quarry. The water collected will be used for dust control and aggregate washing. The capacity of the sump pit will be adequate to contain the collected water so that discharges due to normal operations will not be required. There is the possibility that as a result of extreme storm events a portion of the water would need to be discharged following settling and clarification. In these events, the discharge will be fully controlled and will be tested to ensure it meets applicable water quality requirements prior to discharge. Given these topographic modifications and the excessive storage volumes thus created, the possibility of accidental, unmonitored discharges is essentially eliminated.

7.4.5.2 *Monitoring*

To ensure that discharges meet maximum limits listed in the applicable guidelines described above, as well as in the provincial operating permit that will be required for this Project, stormwater pond discharges will be monitored on an as-needed basis, as stipulated in the provincial permit.

7.4.6 *Residual Effects & Significance*

With the use of standard mitigation measures in the event that acid generating rock is present, no significant adverse residual effects are likely with respect to acid drainage and sedimentation in the marine environment. Residual effects are summarized in Table 7.4-1.

**Table 7.4-1:
Residual Environmental Effects for Geology, Soils and Sediment**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Construction									
Preparation of the plant area; impacts to marine water quality from acid rock drainage	A	See Mitigation Section	1	1	1/1	R	1	Surface water discharge to the marine environment	Not Signif.
Preparation of the plant area; impacts to marine water quality from sediment discharge	A	See Mitigation Section	1	1	1/1	R	1	Surface water discharge to the marine environment	Not Signif.
Operation (Full Scale Phase 5)									
Discharge from the sedimentation ponds	A	See Mitigation Section	1	1	1/1	R	1	Surface water discharge to the marine environment	Not Signif.
Decommissioning									
Decommissioning activities are expected to be comparable to construction activities. Therefore, the same analyses apply.								Surface water discharge to the marine environment	Not Signif.

<u>Legend</u>			
<u>Magnitude:</u>	<u>Geographic Extent:</u>	<u>Frequency:</u>	<u>Ecological / Socio-Economic Context:</u>
U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.	1 = < 1 km ²	1 = < 11 events/year	1 = Relatively pristine area or area not adversely affected by human activity.
0 = Nil - No environmental effect.	2 = 1 – 10 km ²	2 = 11 – 50 events/year	2 = Evidence of adverse environmental effects.
1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)	3 = 11 – 100 km ²	3 = 51 – 100 events/year	
2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)	4 = 101 – 1,000 km ²	4 = 101 – 200 events/year	N/A = Not applicable
3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)	5 = 1,001 – 10,000 km ²	5 = > 200 events/year	A = Adverse

	4 = 37 – 72 months		
	5 = > 72 months		

7.5 GROUNDWATER RESOURCES

7.5.1 *Groundwater Resources*

Groundwater extracted from dug and drilled wells is used for drinking water purposes by the nearest residents living to the east, west and south of the Project site. A total of 23 residences are located in the vicinity of the Project (within 2 to 3.5 km); of these, 17 employ dug wells while 6 employ drilled wells. No water wells are installed in the granite rock that will be quarried.

Three distinct hydrostratigraphic units have been identified in the vicinity of the Project: (1) the granite bedrock present within the Property boundary and extending outside the boundary to the limits of the local granite pluton⁶ The limits of the granite pluton are shown on **Figure 6.1-6**. A certain degree of connectivity is expected between the water bearing fractured granite and (2) the fractured metasedimentary bedrock that surrounds the local granite pluton, and (3) a relatively shallow, unconfined aquifer situated within the granular glacial till overburden where present overlying the bedrock.

7.5.2 *Summary of Conceptual Hydrogeologic Model*

The site is characterized by the topographic high created by an erosion resistant granitic pluton, some 95 m above sea level and extending to depth. This feature was intruded up into metasediments of the Meguma Formation and is the target for aggregate extraction. The metasediments surround the site and granite and host six residential wells that extend into the bedrock. Seventeen shallow private wells tap the more permeable glacial till overburden. Wells are found from 1.0 to 3.5 km away, the nearest being 815 m to the southwest.

Groundwater quality in the two bedrock types (granite and metasediments) is similar with the exception of higher levels of dissolved metals (e.g., iron, aluminium and lead) in the granite. As noted there are no water supply wells in the granite. Naturally occurring uranium is present in the granite at concentrations consistent with distribution of this element in granite rock formations throughout Nova Scotia (MacDonald *et al.* 1992; Ford and Ballantyne 1983). Arsenic is present in the groundwater in both the granite and the metasediments. The metals present in the bedrock are entirely from natural mineralization. The overburden groundwater is much more dilute, reflects local recharge of meteoric water, and exhibits a salt signature close to the marine shore (Section 6.1).

The relatively low permeability of the bedrock (even when fractured) at this site restricts surface water movement to depth and is responsible for the high water table, which is generally never deeper than 6 m below ground surface. Groundwater recharge occurs in all the upland areas of the site, with lateral discharge occurring in localized low areas and in some creeks. Horizontal groundwater flow is outward from the granite, primarily along the upper more weathered bedrock. Fracture frequency analysis shows there is a stronger presence of fracturing in the upper granite bedrock, typically above about 40 m. This line is in fact gradational and fracturing occurs throughout the geologic profile. Stream water quality shows little influence of the bedrock. The distinct difference in the metals concentrations between the granite and the metasediments indicates there is little mixing of groundwater between the two rock types.

⁶ A pluton is a discrete, well defined body of igneous intrusive rock.

There will however be exchange of the shallow groundwater along the boundary between the two units, based on the higher degree of fracturing at the bedrock surface. All local water wells are very far away from this boundary and there are many intervening wetlands and creeks that act as discharge zones.

From a conceptual model point of view most groundwater recharge joins the shallow unconfined groundwater system and moves laterally to onsite low areas and ultimately offsite via creek systems. An analysis of the water budget (**Appendix A**) compares the average annual recharge to the ability of the ground to convey it. The groundwater flow was calculated based on measured hydraulic conductivity, lateral hydraulic gradients and the depth of fracturing (and thickness of overburden where present). The “water-in to water-out” balanced very well for this conceptual model. The fractured portion of the granite can easily convey recharge falling on the pluton to wetlands and creeks located at lower elevations. The overburden on the flatter lands surrounding the pluton can also convey a large portion of the infiltrating precipitation, and the fractured bedrock below can accommodate the remainder.

As described in **Appendix A**, a conservative approach for the impact assessment assumes an elevated hydraulic conductivity (1.2×10^{-7} m/s) extending to depth throughout the quarry. Under these assumptions the drawdown from the completed quarry will be felt at a distance of 400 m or less from the quarry face. Realistically, the average hydraulic conductivity is likely less than the upper range assumed above, and fracture density (and hence transmissivity) decreases significantly at depth, suggesting drawdown is not likely to be observed at 400 m from the quarry face.

7.5.3 Boundaries

7.5.3.1 Temporal Boundaries

Changes to groundwater will occur during the construction phase but are expected to be more pronounced during quarrying, especially during the latter phases when the quarry is approaching maximum lateral extent and depth. The finished (closed) quarry will continue to affect local groundwater flow patterns into the future.

7.5.3.2 Spatial Boundaries

Project-related changes to localized groundwater can be expected within the Project Area (i.e., within the Property boundary) since granite will be quarried within this area. Effects of granite removal on the groundwater regime may extend to areas immediately offsite (the Affected Area). The extent of the Affected Area is defined by the maximum limit of the drawdown cone at full quarry build out. A drawdown cone is defined as the area where the water table is lowered due to the quarry, and is typically conical in shape with the degree of drawdown reducing exponentially away from the quarry. The drawdown cone is constrained by the rate of recharge in the Affected Area, may be irregularly shaped depending upon geologic conditions, and does not extend great distances in these types of rocks. In this case, the drawdown cone will not extend to the nearest drilled well (please see below) and so the Affected Area falls between the property and nearest residence.

7.5.3.3 *Administrative Boundaries*

Potable groundwater quality and surface or groundwater water takings greater than 23 m³/day are regulated by the Province of Nova Scotia. For municipal water supply systems, the province in 2000 adopted the Guidelines for Canadian Drinking Water Quality to ensure that potable water meets national water quality standards (HC 2012). Large scale water takings (much larger than required for residential use) are regulated in the provincial *Activities Designation Regulations*. Water taking is permitted as long as an adverse unmitigable impact does not occur.

7.5.3.4 *Technical Boundaries*

Although preliminary drawdown tests were conducted on boreholes installed in the granite within the limits of the property, these holes were not designed as groundwater monitoring wells but rather to gather samples of the granite resource. Because the boreholes were not screened to restrict groundwater flow into the well, it is not possible to precisely determine the depths in which groundwater was entering the borehole. In addition, the relatively narrow diameter holes did not permit the use of a sufficiently powerful pump to fully stress the water bearing fractures. Despite this, data collected during the summer work programs provide sufficient information to confirm the conceptual model of the local groundwater system, and provided reasonably reliable data regarding the hydrogeological characteristics of the granite aquifer.

With respect to the residential wells, very little information is available regarding the construction of dug and drilled wells. This is not seen as a limitation, given the distance away of the wells and the intervening features that dictate a lack of connection with the site.

Very few drilled water supply wells are present in the vicinity of the Project Area, and with a single exception, all are found east or west of the Property, at a minimum distance of 2.7 km. The lack of groundwater wells within the granite, combined with the paucity of drilled wells in the vicinity and their distance from the Project site, limits the applicability of data collected at these residential wells when investigating the zone near the pit where Project impacts might occur.

The sheer size of the site dictates that investigation points are widely spaced. However the similarity of conditions and uniformity of findings where examples have been investigated allows the analyst to extrapolate conditions with minimal risk.

7.5.4 *Threshold for Determination of Significance*

As noted, groundwater quality and quantity contributes to local ecological systems as well as to potable groundwater supply. With respect to local ecological systems, a significant effect is defined as a decrease in groundwater supply to Affected Areas by 20% and/or an impairment in water quality such that groundwater discharge to surface waterbodies no longer meets Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 1999 as updated).

With respect to potable water supply, a significant effect is defined as any decrease in water availability caused by the Project and/or impairment to water quality such that the potable water no longer meets the criteria listed in Guidelines for Canadian Drinking Water Quality.

7.5.5 Effects on Groundwater

Groundwater can play an important role in sustaining streams and wetlands and the habitats and wildlife that depend on them. Project activities also have the potential to affect groundwater supply and quality outside of the Property boundary. Groundwater is also a potential pathway that can transport contaminants offsite, although in this instance, groundwater will be flowing *towards* the site.

The Project will remove granite from within the Property boundaries, ultimately creating a pit approximately 130 m deep. Once pit development begins, surface precipitation that originally landed on the granite, infiltrated surface fractures, and flowed laterally to help recharge wetlands and lakes near the Property boundaries, will be redirected into the pit and collected in the main sump. At the same time, granite will be removed from below the groundwater table and groundwater inflows to the pit will also be collected in the main sump. Initially, the redirection of surface and groundwater will be minimal since the pit will be small and shallow. As the pit develops over time this effect will become more pronounced as more surface and groundwater is diverted away from existing flow patterns and into the pit. Ultimately, the pit itself acts to draw groundwater from the surrounding granite, since the empty pit represents a region of low pressure towards which groundwater will naturally flow.

Despite this, the magnitude and environmental effects of the redirection of surface and groundwater are expected to be limited and localised. Currently, precipitation falling on 54.7% of the site's surface area is directed by topography to the north, and is lost to Chedabucto Bay through surface water runoff and groundwater flow. This accounts for all precipitation (minus evapotranspiration) within catchment areas F1-F4, M1 and N1-N6 (**Figure 6.2-1**). Some of these catchments, such as F2 and M1, provide surface water and shallow groundwater recharge to Fogherty and Murphys Lake, and the wetlands associated with these lakes before discharging into Chedabucto Bay. Flow from the remaining 45.4% of the site is directed south to tributaries of Reynolds Brook. The portion of the site that will be developed into the quarry contributes 18% of the flows within catchment of Reynolds Brook above Hendsbee Lake will be developed into the quarry. At full development, this surface water will be captured in the pit and will no longer flow to Reynolds Brook.

Under these circumstances, it can be seen that the precipitation falling on roughly 50% of site's surface supports local, rather than regional, ecological features and functions (i.e., on-site and adjacent wetlands and waterbodies) before discharging into the ocean. Removal of granite will, over time, affect local groundwater flows to the north, and by extension, these local wetlands and waterbodies will be affected by the loss of surface water and shallow groundwater recharge.

Precipitation falling on the remaining 50% of the site flows south and contributes to Reynolds Brook. This includes that portion that infiltrates into the groundwater system. However, this overall contribution is small compared to the size of the catchment area that drains to Reynolds Brook. Even at full pit build out, with the maximum amount of surface water diverted into the pit and away from Reynolds Brook is only about 18% of the total Reynolds Brook catchment area measured at the inflow to Hendsbee Lake. The lands adjacent to the pit will continue to contribute locally to offsite watercourses and wetlands; however base flow in these watercourses will be lower at the Property boundary. Given the size of the catchment area removed (portions of subcatchments S1 and S3 totalling 106 ha) compared to the overall watershed that drains to the Hendsbee Lake to the southwest (578.5 ha) is relatively small

(18%), the overall Project impact on groundwater flow to the south, and by extension to downstream features and functions in a southerly direction is considered to be not significant.

With respect to potential Project effects on the localised surface water aquifers that support dug wells, no Project-related impacts are expected. This is because these aquifers are fed by surface precipitation falling within the subcatchment that hosts the wells and not by precipitation falling on areas that will be developed for the Project. As shown on **Figure 6.2.1**, none of the subcatchments affected by Project activities host dug wells and so no effects are possible.

For those who use drilled bedrock wells to obtain potable groundwater, the conceptual groundwater model, supported by groundwater quality data and initial hydraulic conductivity testing, demonstrates that Project-related impacts to potable groundwater supply and quality will be negligible. This can be seen by considering the following:

1. There is no potable groundwater wells drilled in the granite.
2. Drilled wells within the highly fractured metasedimentary rocks access a chemically different groundwater than the one present within the granite (the bedrock unit that will be affected by the Project). These aquifers are not only chemically different, they are structurally different. While certain connectivity can be expected at the boundaries between the granite and metasedimentary bedrock, the fact that the water chemistry is different indicates that the connectivity is minimal and slow to occur.
3. Drill logs indicate that the granite does not exhibit a great number of fractures at depth and so water movement within is expected to be slow. Even at full pit build out, a thick barrier of granite (over 400 m wide) will remain between the pit wall and nearest metasedimentary bedrock where drilled wells are located (even further away). This thick barrier helps to isolate Project-related effects within the granite from affecting the aquifer tapped by wells in the metasedimentary bedrock.
4. The nearest drilled groundwater well is located 815 m from the 50-year pit boundary, far outside of the maximum potential drawdown cone resulting from the pit (400 m); the next nearest drilled well is more than 2.5 km from the pit boundary. The sheer distance provides a significant measure of security for drilled wells in the vicinity of the Project.
5. As noted, because the groundwater movement within the granite is expected to be limited, no groundwater dewatering will be needed to prevent groundwater inflow into the pit (inflows will be simply collected in the sump). The lack of active dewatering wells means that the cone of influence is limited the zone caused by passive drainage into the pit.

Together, these factors demonstrate that impacts to groundwater feeding nearby dug and drilled wells will be not significant.

7.5.6 Mitigation & Monitoring

7.5.6.1 Mitigation

With respect to potential effects on nearby groundwater users, no mitigation measures are proposed at this time since no effects are predicted. In the event that unexpected impacts are detected in the groundwater monitoring program (described below), mitigation measures can be

implemented as required, depending on the nature of the impact. Such measures may include for example, provision of drinking water or artificial recharge near affected ecologic features. In addition, as described in more detail in Section 7.8, wetland and watercourse alteration permits will be required in advance of any damage to these features. The permitting process requires that damaged wetlands are replaced elsewhere through a Wetland Compensation Plan; if this is not feasible or desirable, then other forms of compensation may be considered.

7.5.6.2 *Monitoring*

An adaptive groundwater monitoring program is proposed for the life of the quarry, or until it can be conclusively demonstrated that the quarry will have no measurable effects on potable water quality or quantity. A total of ten pairs of wells may be monitored over the life of the Project; the program would use newly installed wells as well as existing boreholes are present on the site. The wells would be installed over time as the quarry expands, rather than all at once. As the results become known and actual quarry drawdowns compared against predicted values, monitoring well locations can be optimized or eliminated and monitoring frequency reduced if no effects are observed. The groundwater monitoring program is described in more detail in **Appendix A**.

Each groundwater monitoring station would consist of at least a pair of drilled monitoring wells into the bedrock. One of the two wells would be equipped with a water level monitor in the upper 10 m of bedrock (the weathered zone), while the second well would be drilled to the anticipated final quarry depth. Packer testing would be used to select an appropriate permeable horizon within the deeper well to host a water level monitor. If the overburden is found to be substantive and water bearing, a shallow standpipe would be installed in the overburden for monitoring purposes.

The first two sentry well pairs to the south and east of the five year quarry face would be drilled in year zero to establish and monitor the drawdown condition to the south and east of the quarry face, since quarry expansion between years zero and five will occur in the south and easterly directions. If drawdown effects are observed in the eastern well, a third well pair would be installed in year three or four at 400 m east from the quarry face to again test the predicted drawdown condition. Should no effects be measured at 50 m, then no wells would be required at 400 m.

All groundwater monitors would be tested for field permeability for comparison to the original studies. Additional well pairs to the south and west would be installed progressively over the years in keeping with quarry expansion and depending on results of previous well testing, as shown in **Appendix A**.

Groundwater monitoring would consist of seasonal (quarterly) water level measurements plus the use of dataloggers in key sentry wells in line with residential wells. Since no impacts are predicted on private wells over a kilometre away and there is a high level of confidence with this prediction, no private well monitoring program is proposed at this time. However, the groundwater monitoring program is adaptive and if drawdowns at the sentry wells were greater than predicted, additional sentry wells could be added and/or a private well monitoring program could be instituted if deemed necessary following discussions with NSE. Once seasonal baseline conditions (water quality and water level fluctuations) are established the results would be used to determine future seasonal monitoring frequency.

Two baseline water samples per year would be collected, one each in the wet and dry seasons. Samples would be analysed for a basic suite of water quality parameters. Water quality samples would be taken again if/when quarry effects are observed in the sentry wells to determine if the drawdown has had adverse effects on water quality. The need for future water quality sampling would be re-evaluated based on these initial results.

Each well location would be monitored seasonally for a minimum of two years to establish variations over differing meteorological conditions. At the end of two years, the results of program would be discussed with NSE to determine if changes to monitoring frequency and future well locations are warranted.

The monitoring of ground-to-surface water interaction will be achieved using the existing shallow drive point piezometers located in key wetlands plus in Fogherty and Murphys Lakes. The objective of this program is to establish if there is a drying out of wetlands from their baseline conditions. Water level monitoring would be undertaken at the same frequency as in the groundwater monitors but no water samples would be taken. This methodology is non-intrusive to the ecologic features and largely employs drive point piezometers already in place.

In summary, the adaptive groundwater monitoring approach is designed to verify the drawdown predictions described above and in **Appendix A**. It will be progressively implemented as the quarry expands over time and has the additional advantage of being adaptive and flexible, in terms of well locations and monitoring effort, to initial results. This in turn results in a groundwater monitoring program that is reflective of actual quarry expansion and measured Project effects on groundwater.

7.5.7 Residual Effects and Significance

Once the quarry is completed the excavation will be allowed to flood and equilibrate with the existing water table. A residual drawdown cone will result. The depth of the flooded area below the present water table is about 75 m, implying a 300-400 m wide drawdown cone of irregular shape. No residual effects on local wells are predicted (the nearest drilled well is 815 m from the 50-year pit face). Wetlands and watercourses in the 300-400 m area may be affected by some form of depletion by leakage of water out through the groundwater. The significance of this will be in the form of a transition of vegetation types from wetland to upland around the margins of the wetlands closest to the pit, with the effect receding with distance from the pit. Residual effects are summarized in Table 7.5-1.

**Table 7.5-1:
Residual Environmental Effects for Groundwater**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio- Economic Context	Residual Effect	Significance of Residual Effect
Construction and Operation									
Quarry expansion over 50 years; reduction in groundwater recharge to offsite surface water features; changes to water quality	A	See Mitigation Section	1	1	5/6	R	1	Limited reduction in groundwater recharge to offsite surface water features	Not Signif.
Legend <u>Magnitude:</u> U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown. 0 = Nil - No environmental effect. 1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation) 2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability) 3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation) <u>Geographic Extent:</u> 1 = < 1 km ² 2 = 1 – 10 km ² 3 = 11 – 100 km ² 4 = 101 – 1,000 km ² 5 = 1,001 – 10,000 km ² <u>Duration:</u> 1 = < 1 month 2 = 1 – 12 months 3 = 13 – 36 months 4 = 37 – 72 months 5 = > 72 months <u>Frequency:</u> 1 = < 11 events/year 2 = 11 – 50 events/year 3 = 51 – 100 events/year 4 = 101 – 200 events/year 5 = > 200 events/year 6 = continuous <u>Reversibility:</u> R = Reversible I = Irreversible <u>Ecological / Socio-Economic Context:</u> 1 = Relatively pristine area or area not adversely affected by human activity. 2 = Evidence of adverse environmental effects. 7.6 MARINE AND SURFACE WATER RESOURCES

7.6.1 Overview

Surface Water Resources including watercourses and lakes on and immediately adjacent to the site are considered to be a VC because they sustain aquatic and support terrestrial ecosystems, convey stormwater, and can either recharge groundwater resources or drain excess groundwater away from an area. Marine water quality may be negatively affected by sediment laden water in the form of discharge or stormwater runoff. Acid rock drainage generated from the disturbance of Halifax Formation rocks may also affect marine water quality. Good quality water is essential to the wellbeing of a large variety of marine organisms, and is also critical to the long term success and sustainability of the commercial fishery.

Potential impacts of the proposed quarry development upon the baseline hydrological regime are twofold. Firstly, the development may impact upon the baseline hydrological regime by increasing or decreasing flows to, or water levels within surface water resources. This in turn may impact upon established aquatic ecosystems, or (during extreme events) additional runoff may increase the risk of flooding within the downstream environment. Secondly, the development may impact upon the quality of surface water which may in turn affect established aquatic ecosystems.

Details of potential impacts to wetlands are presented in Section 7.8 (Wetlands), while anticipated effects to freshwater and marine species and habitats are described in Section 7.10 and 7.11, respectively. Section 7.4 (Geology, Soil and Sediment Quality) addresses discharges to the marine environment from acid generating rock and sediment-laden stormwater.

7.6.2 Boundaries

7.6.2.1 Temporal Boundaries

The temporal boundaries for the assessment of impacts upon surface water resources are the construction phase (two to three years) and the operational lifetime of the development (50 years). The impacts of climate change have been considered up to 70 years into the future.

7.6.2.2 Spatial Boundaries

The spatial boundaries used for the impact assessment are local (within the site boundary called the Project Area), extending to surface watercourses immediately adjacent that receive drainage from the Project site (the Affected Area). In addition, a more regional boundary is described, which includes potential effects to downstream watercourses within 2 km of the property boundary, provided these watercourses currently receive drainage from the site. In this case, only Reynolds Brook and Hendsbee Lake to the south are located within this regional boundary.

7.6.2.3 Administrative Boundaries

The Nova Scotia *Contaminated Sites Regulations* refers to a number of Ministerial Protocols which include numerical Environmental Quality Standards (EQS). These Standards are

applicable for comparison of analytical results of any spills of petroleum hydrocarbons which may occur on the property.

The Canadian Environmental Quality Guidelines published by Canadian Council of Ministers of the Environment (CCME) are also applicable (i.e., CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, both freshwater and marine – CCME 1999).

The Nova Scotia Pit and Quarry Guidelines also provide liquid effluent discharge criteria that are applicable to this Project, in this case for suspended solids (NSEL 1999).

7.6.2.4 *Technical Boundaries*

No numerical or quantitative modeling was undertaken to assess the impacts of the development on baseline water quality, instead a qualitative assessment is presented. No technical boundaries were identified for the Surface Water Resources VC.

7.6.3 *Threshold for Determination of Significance*

Water Quantity

The quarry development has the potential to impact upon the baseline hydrology in the following ways:

- **Mean Annual Runoff** – As noted, alteration of topography / drainage routes, removal of topsoil / vegetation, and use of water for processing may impact the volumes of runoff discharged from the site, thereby affecting downstream flow-dependent receptors such as streams and wetlands. A significant impact is defined as a predicted change in the mean annual runoff within any off-site watercourse, or flow into any water body, which changes by 20%.
- **Peak Flow** – Project-related alterations to topography and drainage may increase the peak storm flow discharged from the site thereby increasing the risk of downstream flooding. A significant impact is defined as a predicted change in peak flow of water discharged from the site which will measurably increase the risk of flooding to downstream watercourses.

Water Quality

The use of fuels, lubricants and explosives at the site and disturbance of soils and bedrock has the potential to negatively affect water quality discharged from the site thereby impacting downstream receptors. A significant adverse impact on water quality is defined as repeated or sustained surface water discharge from the site exceeds the liquid effluent discharge standards in the Pit and Quarry Guidelines (NSEL 1999) or criteria listed in the CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, both freshwater and marine (CCME 1999).

The Pit and Quarry Guidelines (NSEL 1999) stipulate that:

“All storm run-off from the operating site and all liquid effluents resulting from the operation shall be collected and treated to meet the following suspended solids concentrations prior to discharge into a watercourse or beyond the property boundaries:

(a) maximum suspended solids concentration in an grab sample – 50 mg/l;

(b) maximum arithmetic monthly average suspended solids concentration - 25 mg/l"

CCME Guidelines for water quality (1999) recommend the following suspended solids criteria for the protection of aquatic life (both freshwater and marine):

- Clear flow: maximum increase of 25 mg/L from background levels for any short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for longer term exposures (e.g., inputs lasting between 24 h and 30 d).
- High flow: maximum increase of 25 mg/L from background levels at any time when background levels are between 25 and 250 mg/L. Should not increase more than 10% of background levels when background is ≥ 250 mg/L.

For contaminated surface water (i.e., such as might exist following a hydrocarbon spill or other incident at the site) environmental quality standards (EQS) have been developed by NSE and a list of potential contaminants of concern is also available (NSE 2014). NSE's Table 3 Tier 1 Environmental Quality Standards for Surface Water (ug/L) is applicable at this site. Table 3 provides criteria for a variety of potential contaminants in both fresh and marine surface waters. All criteria are for the protection of aquatic life.

7.6.4 Effects on Surface Water Resources

Freshwater

Of the total site area, the development will affect approximately 180 ha of quarry and a 28 ha coastal platform for the processing plant and aggregate stockpiles. The vegetation and soils in these areas are likely to be stripped leaving bare rock surfaces and thereby increasing the volume and peak rate of runoff discharged from the site.

Following development, the mean annual runoff is expected to increase by 10% on average across the 354.5 ha site, giving an increase in annual runoff from 1 865 592 m³ to 2 171 500m³ when the site is fully developed (**Appendix C**).

Measures are recommended to convey runoff from operational areas to retention ponds reducing the number of discharge points from the site. The mean annual runoff from catchments N4, N5 and S3 (**Figure 6.2-1**) will be increased significantly. The mean annual runoff of catchment F4, M1, N2, N3 and N6 will be reduced as flow is diverted from these to catchments N4, N5 and S3.

The impact upon the hydrological regime of off-site surface water resources is expected to be as follows:

- Murphy's Lake – the mean annual runoff into this water body is expected to be reduced by about 15% at full pit build out.
- Watercourse 3 – the mean annual runoff discharged from the site into this watercourse is expected to be reduced by 70% as development of the pit progressively redirects runoff away from this watercourse and into the pit sump. This watercourse discharges into a wetland that eventually drains to Reynolds Brook. At full build out, the quarry will occupy

106 ha or 18% of the Reynolds Brook catchment above Hendsbee Lake, which has a surface area of 578.5 ha at the inflow to Hendsbee Lake.

- South-West (off-site) Watercourse – the mean annual runoff from the site into this watercourse is expected to decrease by 5%. This watercourse and Reynolds Brook are tributaries to Hendsbee Lake.

Stripping of vegetation and soils across the site is expected to lead to an increase in the peak flows leaving the site by 11% for a 1:25 year event and 8% for a 1:100 year event while the volume of runoff generated post development will be increased by 17% for a 1:25 year event and 13% for a 1:100 year event.

The increase in peak flow and flood volumes attributable to the development are relatively minor and given that there are no downstream watercourses susceptible to flooding, these increases are not considered significant. Therefore, it is not considered necessary to attenuate peak flows on-site to ensure that the pre-development discharge rates are not exceeded.

It is not possible to quantitatively assess the un-mitigated impact of the development upon the baseline water quality conditions. Nonetheless qualitatively the impacts could be as follows:

- Geochemistry – quarrying may expose elements naturally occurring within soils and geology to rainfall and oxidation, potentially mobilizing elements into any discharge from the site. From the water quality monitoring it can be seen that pH is low and aluminum, iron and lead are already found at elevated levels within the surface water environment. On the other hand, whole rock chemistry data collected on site indicates the granite is chemically stable and ideally suited to aggregate production.
- Ammonia and Nitrate - the use of Ammonium Nitrate-Fuel Oil (ANFO) blasting agents leave explosives residues high in ammonia and nitrate within areas where blasting has occurred. These dissolved compounds are easily mobilised by runoff.
- Suspended Solids – quarrying activities will include vegetation removal potentially increasing concentrations of suspended solids within stormwater runoff. Dust will be produced when rock is blasted and later crushed; when this dust comes into contact with stormwater runoff, increased suspended solids concentrations may result.

Since surface water flows will be collected in sedimentation ponds and pit sumps, both of which can overflow harmlessly in the event of a prolonged storm event (Section 3.3.7), the operation will permit water quality monitoring and treatment as needed prior to controlled discharge. The volume of sedimentation ponds and sump pits will be sufficient to contain water on-site for reuse. Given these considerations, no significant adverse effect on surface water quality is predicted.

Marine Water

The potential Project-related effects on marine biota are described in Section 7.11 (Marine Species and Habitats). Section 7.4 (Geology, Soil and Sediment Quality) addresses discharges to the marine environment from acid generating rock and sediment-laden stormwater.

Surface water flows that currently discharge north into Chedabucto Bay will be diverted into retention ponds near the processing plant and additionally (later) into a pit sump located in the quarry floor. Approximately 55% of the Black Point Project site currently flows north into the

Bay. The retention of this water and use for dust suppression and aggregate washing will not affect the water quality or water chemistry in Chedabucto Bay.

Surface water that collects in the ponds and sump is retained until suspended particles settle out of the water column. Water will not be discharged on a continuous basis; when discharge is required to lower the level in the ponds or sump, water will be tested to ensure it meets water quality standards listed in the operating permit, which in turn will be based on the guidelines cited in Section 7.6.3 (Threshold for Determination of Significance) above. Apart from potential effects described elsewhere in the EIS, no Project related effects on Marine Water Resources are anticipated.

7.6.5 Mitigation & Monitoring

In order to reduce the potential impacts of the development on the baseline surface water environment as identified above, the following mitigation measures will be applied:

- Retention or sedimentation ponds will be used near the processing plant while the quarry pit will employ sumps to collect water inflows. Topographic controls (sloping the ground to the south) will ensure that overflow, should it occur, will collect against the south cliff and in the pit, rather than be permitted to discharge directly to the ocean;
- Double walled and or/fully bermed fuel and chemical storage reservoirs will be used;
- The Environmental Management Plan will include a discrete Erosion and Sediment Control Plan to ensure the proper management of stormwater flows during construction and operation. The EMP will also contain a Stormwater Management Plan that describes the construction and operation of drainage swales and stormwater management ponds.
- The EMP will include an Emergency Response and Spill Contingency Plan combined with incident prevention and emergency response training to minimize the risk of accidental spills and to rapidly react to any incident that may occur;
- The Emergency Response and Spill Contingency Plan will include spill dispersion modelling in the marine environment to aid in rapid and effect emergency response.
- The Proponent will contract with a local emergency response consultant to ensure that additional resources and expertise are available in the event of an accidental spill in the marine environment;
- To mitigate reductions in surface flows that supply nearby wetlands, the Proponent in collaboration with NSE implement a Wetland Compensation Plan and associated inspection/monitoring program; and
- All surface water discharges from retention ponds and pits will be sampled as per requirements listed in the industrial operating permit and the Pit and Quarry Guidelines to ensure water quality conforms to applicable guidelines.

7.6.6 Retention Ponds

Runoff from the working areas of the quarry and associated infrastructure will be conveyed to flow retention ponds as shown in the Figures of the Surface Water Assessment Technical Report (**Appendix C**). These retention ponds will be constructed upstream of the final discharge point to improve the quality of any water discharged from the site. Two ponds, each with a volume of approximately 6,000 m³ are proposed for the processing plant area, while a pit sump will contain water generated within the quarry proper. These features are connected through pumps and piping, allowing water transfer between them to ensure that stormwater can be managed and aggregate wash water is always available.

The retention ponds will be designed in accordance with Nova Scotia Department of the Environment Erosion and Sedimentation Control Handbook guidelines (NSE 1988) to intercept sediment laden runoff and allow sediment to settle out, thereby reducing the amount of sediment leaving the disturbed area and protecting local watercourses and Chedabucto Bay from excessive sedimentation.

The proposed design features are as follows:

- Permanent Pool – a permanent volume of water will be retained within the pond at all times to ensure treatment of stormwater discharged from the site. The permanent pool will be sized to contain at least 190 m³ per ha of catchment. Based on the mean annual runoff, this equates to at least 11 days of residence time within the pond prior to discharge.
- Flood Conveyance – flood events up to and including a 1:100 year event + 16 % to account for increases in precipitation due to climate change can be conveyed through the pond. Discharge will occur via pumps from the pit once water testing has been conducted.

For the purposes of stormwater management, the quarry development will progress in two phases, and measures will be implemented accordingly:

- Initial Construction: Construction of the lower platform and access road, years 1-3 (2017-2020). During this phase, runoff from the lower coastal platform area (28 ha) will be conveyed to Plant Pond 1 and Plant Pond 2 situated against the south side of the lower platform. Discharge (if needed) will be into the marine environment, likely via the western property limit. Water will be re-used for processing or tested to ensure water quality guidelines are met and discharged when needed.
- Operations: Not including initial quarrying for site preparation, full quarrying will commence in year 3 (2020), progressing from north to south. Runoff and infiltration within the quarry will be collected within sumps (ponds) with excessively large volumes to ensure sufficient water is available for processing. Discharge would only be effected following analysis, and if needed, treatment.

As noted, the settling ponds and pit sump are designed to serve as an integrated water management system, allowing transfer of water between them to ensure ample processing water is available and allowing treatment of stormwater prior to discharge. At this stage of the Project, the above measures and design detail are considered preliminary, based on current designs. The drainage strategy will be revisited during the detailed site design that precedes permitting.

7.6.7 Fuel and Chemical Storage

All fuels and chemicals stored or used on site will be contained within fit-for-purpose containers and stored within designated storage areas. In order to prevent pollution of the surrounding environment due to an accidental spillage, the designated storage areas will be situated on impermeable surfaces with containment provided. The volume of the berm and sump will be sized to contain at least 110% of the largest tank being stored within the designated storage area, as per fuel storage regulations.

7.6.8 Monitoring

The normal operating procedure will be to reuse water within the operation and not have direct discharges to Chedabucto Bay. In the event a discharge is needed, the water will be sampled prior to discharge and the sample submitted for laboratory testing, as described in the Surface Water Monitoring Program included within the Environmental Management Plan. The sampling and testing will be done in accordance with site discharge monitoring requirements applicable to the operation. The analysis will include parameters required by the effluent discharge standards of the Nova Scotia Pit and Quarry Guidelines (NSEL 1999) and any other parameters or conditions listed in the industrial operating permit.

Where monitoring results exceed the guideline values listed in the Pit and Quarry Guidelines, a review of site activities will be undertaken to identify the source of pollution and remedial measures will be implemented.

The success of the Wetland Compensation Plan will be monitored over time as determined in collaboration with NSE; other water features not directly included in the Plan will be inspected to detect hydrological changes potentially caused by the Project – the frequency and timing of these inspections will be outlined in the Plan.

7.6.9 Residual Effects & Significance

Taking into account the mitigation measures outlined above, the residual impacts of the development are:

- Mean Annual Runoff – stripping of vegetation and soils from the operational areas is expected to increase the mean annual runoff discharged from the site by 10%. Much of this will flow north into Chedabucto Bay as is currently the case. Given this, the impacts on nearby surface water resources and associated downstream aquatic ecosystems are not considered to be significant (i.e., less than 20% change). Diversion of flows into sumps and retention ponds will reduce flows to some off site surface water resources (Murphys Lake and Reynolds Brook) and increase flows to others. The impacts of these changes will be felt slowly as the quarry development proceeds. Estimates indicate that there may be 15% decrease to Murphy's Lake by year 20 although the exact timing is difficult to predict. With respect to Reynolds Brook and Hendsbee Lakes, the effects from gradually reduced inflows as surface water is diverted into the quarry will be not significant, given that current flows from the site make up only about 18% and 13% of total flows to these water features, respectively.
- Peak Flow – vegetation and soil removal from operational areas is expected to increase the peak flows leaving the site by 13% for a 1:25 year and 16% for a 1:100 year event. Post development runoff volume will be increased by 18% for both 1:25 and 1:100 year

events. Given that these increases are relatively minor and that there are no downstream receptors susceptible to flooding, the impacts of these effects are not considered to be significant.

- Water Quality – Standard pollution prevention measures will be adopted at site to prevent accidental spills. Runoff from the working areas of the quarry and associated infrastructure will be conveyed to flow retention ponds and sumps. The retention ponds and sumps will allow the water to be reused on-site for dust control; discharges will be restricted to periods of extreme storm events. These discharges will be sampled and tested to ensure the applicable discharge standards are achieved. Given this, the residual adverse impacts on surface water are not expected to be significant.

**Table 7.6-1:
Residual Environmental Effects for Surface Water**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Construction									
Preparation of the plant area; impacts to fresh and marine water quality and habitats from erosion, siltation and accidental spills	A	See Mitigation Section	1	1	1/1	R	1	Changes to surface water quality	Not Signif.
Operation									
Impacts to fresh and marine water quality and related environments from erosion, siltation and accidental spills	A	See Mitigation Section	1	1	1/1	R	1	Changes to surface water quality	Not Signif.
Effects to on-site watercourses, Murphys Lake and Reynolds Brook from diversion of surface and groundwater into the pit over time	A	See Mitigation Section	1	2	5/6	I	1	Limited reduction in flow; potential improvement in water quality	Not Signif.
Decommissioning									

Decommissioning activities are expected to be comparable to construction activities. Therefore, the same analyses apply.

Legend

Magnitude:

U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.
0 = Nil - No environmental effect.

1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)

2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)

3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)

Geographic Extent:

1 = < 1 km²
2 = 1 – 10 km²
3 = 11 – 100 km²
4 = 101 – 1,000 km²
5 = 1,001 – 10,000 km²

Duration:

1 = < 1 month
2 = 1 – 12 months
3 = 13 – 36 months
4 = 37 – 72 months
5 = > 72 months

Frequency:

1 = < 11 events/year
2 = 11 – 50 events/year
3 = 51 – 100 events/year
4 = 101 – 200 events/year
5 = > 200 events/year
6 = continuous

Reversibility:

R = Reversible
I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.
2 = Evidence of adverse environmental effects.

N/A = Not applicable

A = Adverse

P = Positive

7.7 TERRESTRIAL ECOSYSTEMS, HABITAT AND VEGETATION

This section discusses the potential impacts of the Project on terrestrial habitat, as well as vascular plants and non-vascular vegetation. Freshwater aquatic vascular plants are also included here because of expected similarity of effects and mitigation to those for terrestrial vegetation. Marine vegetation is discussed in Section 7.11 and flora SAR is discussed in Section 7.12. Effects on terrestrial flora are a pathway to other VECs including wetlands, SAR, wildlife, hunting or gathering activities, and land-use. These are discussed respectively in Sections 7.8, 7.12, 7.9, 7.13 and 7.14.

7.7.1 *Boundaries*

The spatial boundaries include all terrestrial habitats within the Black Point Quarry property boundary including the access road.

The temporal boundaries will include all three phases of the Project including construction, operation and decommissioning. No administrative or technical boundaries were employed in the effects assessment of this VC.

7.7.2 *Threshold for Determination of Significance*

A significant adverse effect on terrestrial habitat and vegetation would be a decline in abundance and/or a change in distribution beyond which natural recruitment (reproduction and immigration from unaffected areas) would not return the population to its pre-project level within several (3-5) generations.

7.7.3 *Effects on Terrestrial Habitat and Vegetation*

7.7.3.1 *Construction*

Most if not all of the direct interactions between the Project and terrestrial vegetation will occur as a result of the ground disturbance and other activities associated with the construction phase and progressive development of the Quarry. As described in the Project Description (Section 3.0), the construction phase of the Project is planned in a phased approach where portions of the site will be progressively cleared the open pit mine expanded. Despite this temporal component of the construction activities, this assessment examines the effects construction activities will have on terrestrial vegetation regardless of when, relative to the life of the project, these effects will occur.

Construction activities associated with the Project will result in temporary or permanent adverse effects on terrestrial and freshwater aquatic flora. Potential detrimental effects to terrestrial flora will result from site preparation (clearing/grubbing/grading/blasting), road, power line and building construction, and may also be caused by associated dust, erosion/sedimentation, and possible introduction of invasive species. Potential adverse effects on terrestrial and aquatic flora, habitat, communities, and individuals during construction may also occur as a result of accidental events. Effects can be limited to the footprint of the Project, or extend to adjacent lands as indicated below. Specifically, during construction, potential adverse effects on vegetation and habitat include:

- Direct and indirect mortality of plants;
- Temporary or permanent loss or alteration of habitat and habitat availability;
- Impairment from changes to wind exposure and microclimatic conditions; and
- Mortality or impaired growth due to accidental events.

Mortality of Plants and Loss or Alteration of Habitat

Site clearing/grubbing/grading will result in the removal of vegetation. This represents a loss of availability of vegetation habitat, as well as direct mortality of the vascular and non-vascular plants in the area affected. For the purpose of this EA, it is assumed that all the existing vegetation in the entire footprint of the Black Point Quarry, fill areas and plant location will be permanently lost over the lifetime of the Project (over 50 Years), though the development may integrate small amounts of habitat, such as amenity green space (ornamental plantings and turf). Habitat loss within the footprint of the Project area will amount to 212.48 ha (including wetland habitat); however, since the open pit development is progressive over the life of the quarry, the entire 213 ha will not be exposed until the last few years of quarry operations. Site rehabilitation will enable partial recovery of habitat at that time. Lay-down areas will be located within the planned footprint and therefore will not require additional space. As the quarry activities progress, the affected habitats will be replaced with exposed soil / rock surfaces and buildings. In sections where quarrying has been completed, site rehabilitation measures will be implemented to initiate re-vegetation in exposed areas that will not be disturbed further by the operation.

Clearing may also change wind exposure and microclimatic conditions in adjacent forests, resulting in some die-off and reduced growth of forest species until edge vegetation matures. The area surrounding the Project site consists of primarily open habitat including a mix of forest, barren and tall shrub habitat and as such there is little potential for this type of edge effects on forests.

These effects are not considered to be significant for common flora populations, and no mitigation beyond standard environmental protection measures is recommended.

Erosion and Sedimentation

Clearing and grubbing required for all Project components, results in disturbed soil surfaces without cover of vegetation. Exposed soil is vulnerable to erosion, and the resulting sedimentation may smother vegetation or impair plant growth in adjacent terrestrial and aquatic habitats. With the implementation of standard sediment and erosion control measures as outlined in Section 7.4, effects on common terrestrial and aquatic vegetation are not considered significant, and no further specific mitigation is recommended.

Fugitive Dust

Earthwork, movement of construction and transportation machinery, and storage of soil and construction materials may result in development of fugitive dust. The deposition of dust on the leaf surfaces of near-by vegetation may have temporary inhibiting effects on photosynthesis and transpiration in the affected plants, potentially resulting in slower growth rates. Noticeable dust

deposition is expected to not exceed a few metres. Standard dust-abatement measures and measures for the protection of air quality as outlined in Section 7.1 will reduce the effects of dust on vegetation in all habitats. Given the site's climate (relatively frequent and extensive precipitation, these effects are not considered to be significant for common vegetation, and plants will recover. No special mitigation is recommended.

Spills, Malfunctions and Accidents

The potential effects of spills, malfunctions and accidents and recommended mitigation measures are discussed in more detail in Section 7.18. Spills could directly kill vegetation and also create soil conditions unsuitable for vegetation growth.

7.7.3.2 Operation

No significant direct effects (mortality, loss of habitat) on vegetation communities are expected during operation beyond those associated with the progressive quarry development as discussed above for the construction phase. Possible adverse effects on terrestrial and aquatic flora of a minor nature may, however, occur due to fugitive dust, road maintenance and traffic. There is also potential for adverse effects on flora during operation from spills and accidental events, which are further discussed in Section 7.18.

During operation, potential adverse effects on flora habitat, communities and individuals include:

- Fugitive dust;
- Impairment from chemicals; and
- Mortality or impaired growth due to accidental events.

Fugitive Dust

Effects on terrestrial and aquatic flora during the operation phase of the project are similar to the construction phase. These effects are not considered to be significant for common vegetation, and plants will recover. No special mitigation is recommended.

Increased Levels of Toxic and Deleterious Substances (Salt)

Road salt used on roads within the Black Point Quarry may adversely affect immediately adjacent terrestrial vegetation and soil quality. Salt will be used sparingly and only when crushed stone cannot be used effectively. With the application of mitigation measures, significant adverse effects on vegetation from road salt are not expected.

Spills, Malfunctions and Accidents

The potential effects would be similar to construction, above.

7.7.3.3 Decommissioning

Potential effects of Project activities during the decommissioning phase are somewhat similar to the potential effects during the construction phase. Re-vegetation of reclaimed areas after the decommissioning of the pit, facilities and roads will occur. This activity will have positive effects on the vegetation of the area by initiating re-establishment of vegetation in disturbed areas.

Temporary adverse effects on terrestrial and freshwater aquatic flora, habitat, communities and individuals could occur from infrastructure removal and associated soil disturbance, associated dust, erosion and sedimentation. Potential adverse effects on flora could also arise from spills and accidental events, further discussed in Section 7.18.

7.7.4 Mitigation & Monitoring

A general set of environmental mitigation measures specific to the three project phases (construction, operation, decommissioning/rehabilitation) will be defined in an Environmental Management Plan (EMP). The EMP will also establish monitoring plans to ensure mitigation measures are implemented and effective. Specific monitoring commitments are also specified in the summary table below (Table 7.7-1). The following mitigation measures are recommended specifically to avoid and minimize impacts on terrestrial habitat and vegetation:

During Construction:

- Reduce area of Project footprint and temporary lay-down areas to that which is absolutely necessary;
- Mark Project boundaries to prevent accidental impacts outside the work area;
- Remove/ and salvage topsoil (i.e., approximately upper 30 cm); store separately and reuse for site restoration where possible;
- Control erosion and sedimentation as outlined in Section 7.4;
- Dust-prevention measures and dust abatement measures outlined in Section 7.1, will also protect local flora and habitats;
- Stabilize and rehabilitate areas of disturbance;
- Use local native vegetation in restoration – consideration will be given to the preferential use of vegetation types of interest to the Mi'kmaq; and
- Efficacy of the erosion and sediment control measures, as well the establishment of native flora should be monitored through an EMP (see Section 10.0).

During Operation:

- Vegetation management will be conducted by mechanical cutting (e.g., mower, brush cutter);
- Mitigation measures for the protection of watercourses (see Section 7.6 and 7.10) will help to protect terrestrial and freshwater aquatic vegetation and habitats; and
- Mitigation measures pertaining to air emissions pollution control as outlined in Section 7.1 will also protect common lichen species.

Mitigation measures for potential impacts during decommissioning are similar to those for construction. Decommissioning activities will be conducted in accordance with all applicable regulatory requirements at the time and a decommissioning plan. The decommissioning plan will include a detailed rehabilitation plan. The proponent is committed to implement as part of the rehabilitation specific habitat enhancement measures that maximize terrestrial and freshwater habitat diversity and quality.

7.7.5 *Residual Effects & Significance*

Table 7.7-1 provides a summary of recommended mitigation measures and residual environmental effects after successful implementation of the mitigation measures described above.

With the implementation of the recommended mitigation measures, Project activities are not likely to result in significant adverse residual effects on terrestrial ecosystems, habitat and vegetation.

**Table 7.7-1:
Residual Environmental Effects for Terrestrial Habitat and Vegetation**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Direct plant mortality, habitat removal or alteration due to site preparation, clearing and grubbing.	A	See Mitigation Section	1	2	3/1	R	1	Habitat loss	Not Signif.
Indirect plant mortality as a result of potential erosion, sediment loading, stormwater discharges	A	See Mitigation Section	1	1	3/1	R	1	Habitat loss	Not Signif.
Displacement or loss of natural / native habitat due to the introduction of invasive species.	A	See Mitigation Section	1	2	5/7	R	1	Displacement / Habitat loss	Not Signif.
Indirect plant mortality and impairment as a result of fugitive dust emissions during construction and operation.	A	See Mitigation Section	1	2	5/2	R	1	Plant mortality	Not Signif.

Increase in levels of toxic and deleterious substances due to infrastructure maintenance (salt).	A	See Mitigation Section	1	1	5/1	R	1	Plant mortality	Not Signif.

--	--	--	--	--	---	--

7.8 WETLANDS

7.8.1 *Boundaries*

The spatial ecological boundaries for wetlands include all wetlands within the footprint of the proposed quarry, plant, fill areas and access road. Wetlands that are hydrologically connected to areas located in the footprint of Project infrastructure are also included in the ecological boundaries as these are considered to be within the zone of influence of the Project.

Temporal ecological boundaries encompass the entire year, since interactions between wetlands and project components, or effects of short-term project activities, can occur or can extend year round. However, wetlands are less sensitive during the winter, when they are frozen and less susceptible to substrate disturbance. Wetlands are more sensitive during spring, summer and fall when they tend to be utilized by numerous wildlife species including birds. The temporal boundaries extend over all three phases of the Project including construction, operation and decommissioning. No administrative or technical boundaries were identified for the Wetland VC.

7.8.2 *Threshold for Determination of Significance*

A significant adverse effect from the Project on wetlands is defined as an effect that is likely to cause a permanent net loss of wetland function as established during the wetland evaluation. An adverse effect that does not cause a permanent net loss in wetland function is considered to be not significant.

7.8.3 *Effects on Wetlands*

Most if not all of the direct interactions between the Project and wetlands will occur as a result of the ground disturbance and other activities associated with the construction phase and progressive development of the Quarry. As described in the Project Description (Section 3.0), the construction phase of the Project is planned in a phased approach where portions of the site will be progressively cleared and prepared for the open pit development. This will extend over most of the Project's lifespan and will be accompanied by expansion of the open pit mine. Despite this temporal component of the construction activities, this assessment examines the effects construction activities will have on wetlands regardless of when, relative to the life of the project, these effects will occur.

As described in Section 6.4.2, field surveys have identified 22 wetlands within the Black Point Study Area (Figure 6.4-2). The majority of wetland habitat identified consists of open bogs and riparian fens which range in size from approximately 16.5 ha to <0.5 ha. Sixteen of the wetlands identified will be partially or completely infilled / removed, totalling approximately 17.5 ha (Figure 7.8-1). These are summarized in Table 7.8-1 below.

**Table 7.8-1:
Summary of Predicted Loss of Wetland Habitat**

Wetland #	Type	Size ha	Estimated Area Lost (ha)	Predicted Impact
WL1	Bog/Swamp Complex	16.5	0.2	Partially infilled (0.2 ha) during construction
WL2	Fen/Swamp/Marsh Complex	6	0.7	Partially infilled (0.7 ha) during construction.
WL3	Riparian Fen	0.5	0.5	Infilled during construction
WL4	Bog	0.2	0.2	Infilled during construction
WL5	Riparian Fen	0.5	0.4	Partially infilled (0.4 ha) during construction.
WL6	Bog	0.3	0.3	Infilled during construction
WL7	Riparian Treed Swamp	0.5	0.2	Partially infilled (0.2 ha) during construction.
WL8	Swamp/Bog/Fen Complex	10.3	-	Currently avoided but near the Project boundary.
WL9	Bog	4.6	-	Currently avoided but near the Project boundary.
WL10	Riparian Treed Swamp	0.1	-	Currently avoided but near the Project boundary.
WL11	Bog	9.0	8.1	Partially removed (8.1 ha) during construction.
WL12	Bog/Fen Complex	0.3	0.3	Removed during construction.
WL13	Treed Swamp	0.6	0.6	Removed during construction.
WL14	Fen/Bog Complex	6.2	6.2	Removed during construction.
WL15	Riparian Fen	0.07	0.07	Removed during construction.
WL16	Bog	0.45	-	Crossed by Power line corridor.
WL17	Bog/Swamp Complex	0.74	-	Currently avoided but near the Project boundary.
WL18	Bog	0.07	0.04	Partially infilled (0.04 ha) during construction
WL19	Bog	0.04	0.03	Partially infilled (0.03 ha) during construction
WL20	Bog	0.15	0.02	Partially infilled (0.02ha) during construction
WL21	Fen	0.19	-	Currently avoided but near the Project boundary.

Wetland #	Type	Size ha	Estimated Area Lost (ha)	Predicted Impact
WL22	Riparian Fen	0.1	0.02	Partially infilled (0.02 ha) during construction.
Total Area		57.3	17.5	

Wetlands can be adversely affected by direct removal, fragmentation, disturbance, erosion/ sedimentation, and changes to hydrology, introduction of invasive species and release of hazardous materials. These impacts can interfere with wetland function, including species diversity. The effects can result from short term activities during the construction phase and decommissioning phases, as well as long-term activities during the Project operation.

7.8.3.1 Construction

The following discussion of potential impacts applies to all wetland areas in close proximity to the Project footprint.

Wetlands depend on a certain level of soil humidity. If the water regime is changed, changes will occur to the vegetation, character and functionality of the wetland. In addition to the direct impacts due to localized infilling or removal, wetlands surrounding the Project footprint could potentially be adversely affected by changes to the hydrology, due to impeded or redirected drainage caused by the construction of the Project infrastructure and pit. Wetlands located up-gradient of the proposed construction may be flooded if drainage is impeded. Wetlands located down-gradient could be adversely affected if surface water flow, including stream flow, decreases. If stormwater from the roads which is collected in roadside ditches is allowed to enter these wetlands in amounts exceeding natural pre-construction flow, similar adverse effects are likely.

All of the above wetlands could also be adversely affected by sediment entrained in surface water runoff during construction activities. Exposed soil associated with site clearing, grubbing, grading, stripping and storing of topsoil or construction materials and reclamation of the Project site during decommissioning may result in erosion and subsequent sedimentation. Sediments carried into wetlands could smother existing vegetation, but may also contribute nutrients to the wetlands. Changes in nutrient levels will change water quality and potentially plant communities in the wetlands. Effects would be greatest in low nutrient systems such as treed bogs and shrub bogs, and would likely result in adverse effects on wetland function.

Dust and minerals from road runoff may have similar effects. Fugitive dust will be formed during the construction phase or decommissioning phase from soil movement, soil and material storage, and the movement of construction equipment and transportation vehicles. The dust may cover native vegetation and smother it, but dust also deposits minerals and nutrients into the wetlands.

Wetlands in close proximity to the Project footprint may be adversely affected if accidental spills of deleterious substances such as fuels, lubricants or engine oil occur during the operation of construction and transportation equipment (see discussion in section 7.18).

Where construction activities occur in wetlands, there is potential for introduction of invasive species. Seeds, roots or “rootable” fragments of invasive species may be stuck to construction equipment, transportation vehicles or shoes of workers. These propagules may be introduced into wetlands directly when equipment or people access the wetlands, or indirectly via runoff or dust from the roads. Invasive species such as Purple Loosestrife (*Lythrum salicaria*), are known to severely degrade wetland habitat and thus one or more of wetland functions. The potential for introduction of invasive species is highest in wetlands in or near the construction zone, including lay-down areas, followed by wetlands downstream or down-gradient of those areas. Since the amount of traffic during construction will be increased over current levels, especially long distance traffic, the likelihood of introduction of invasive species is elevated. However, during the field surveys carried out in 2010 and 2014, no Purple Loosestrife was noted in the Project area.

Wildlife using the wetlands near the construction zone as habitats may be disturbed by noise or lights, or impacted by accidental spill of hazardous materials such as fuel or lubricants from construction and transportation equipment during the construction and decommissioning phases. These effects are discussed in Section 7.9 and Section 7.12.

Runoff from acid generating slates exposed due to construction activities is a potential and may negatively impact wetland habitat should runoff from this material enter this habitat type.

Directly Impacted Wetlands

Wetlands 1, 3, 6, 14 and 17 occur near or form the headwaters of small watercourses throughout the Site and therefore provide critical hydrological functions. It is notable that none of the watercourses present within the Study Area are fish bearing streams. Wetlands 11, 18, 19 and 20 may serve as groundwater recharge sites. As such they were found to provide critical hydrogeological functions. Wetland 2 likely provides critical shoreline protection function during storm events.

Wetlands 1, 2, 3, 6, 11, 14, 18, 19, and 20 represent common wetland types in the region. Wetlands 3 and 6 will be completely infilled / removed. Wetlands 1, 2, 11, 14, 18, 19 and 20 will be partially infilled (15 ha combined) therefore approximately 15.8 ha of wetland habitat providing “critical wetland function” will be lost. These functions represent red rated significant functions based on the NovaWET assessment and are typically unique or rare or associated with a high risk to the watershed if lost (see Section 6.4 for further details).

Wetlands 4, 5, 7, 12, 13, 15 and 22 are not of high value in terms of wetland function, and belong to a wetland class that is common both to the local area and throughout Nova Scotia. One lichen species of conservation concern was found in WL12 although this species is ranked S2S3 by ACCDC and as such is not considered a “Red Rated Significant Function”. All of these common relatively “low value” wetlands do not support plant species at risk, and are not considered providing critical wildlife habitat. Wetlands 4, 12, 13 and 15 will be completely infilled / removed while wetlands 5, 7 and 22 will be partially infilled resulting therefore in the loss of approximately 1.7 ha of relatively common “low value” wetland habitat.

A wetland alteration approval will be obtained from NSE prior to construction in any of these wetlands. In conjunction with this approval, compensation will be developed for the loss of these wetlands, as NS aims to prevent net loss of wetland function. The compensation plan will be subject to approval by NSE.

Potentially Indirectly Impacted Wetlands

A number of wetlands have been identified in close proximity to the Project footprint (WL8, WL9, WL10, WL16, WL17 and WL21). These wetlands are considered to be potentially impacted through indirect means such as increased sedimentation, alterations to hydrology, disturbance and impacts resulting from accidental spills or dust / runoff from roads.

Wetland 21 (0.19 ha) is located in the northern end of the Study Area, downstream from the Project footprint and has the potential to be indirectly impacted.

WL 16 (0.45 ha) is located in the southeast corner of the Study Area. The power transmission corridor is proposed to run through this wetland and may result in changes to vegetation structure, soil compaction or alteration to hydrology.

Wetland 17 (0.7 ha) is located at the southeastern end of the Study Area. The access road will be constructed adjacent to the east boundary of this wetland which may alter hydrology. This wetland may also be indirectly impacted by uncontrolled site runoff leading to sedimentation, dust deposition, or accidental spills.

Wetlands 8, 9 and 10 (10.3 ha, 4.6 ha and 0.1 ha respectively) are located along the western end of the Study Area in close proximity to the proposed footprints of the pit and fill areas. These wetlands could be indirectly impacted by uncontrolled site runoff leading to sedimentation, changes in hydrology, dust deposition, or accidental spills.

Wetland alteration approvals will be obtained from NSE for those wetlands where indirect adverse effects are considered likely to occur. Indirect adverse effects will be detected through the implementation of the EMP. Compensation for indirect adverse effects to wetlands will be discussed with NSE during the wetland alteration approval process.

7.8.3.2 Operation

During the operation phase, wetlands located in close proximity to the Project footprint can be adversely affected by alteration of hydrology, release of hazardous materials during maintenance activities or accidents and malfunctions, dust/ sedimentation, introduction of invasive species, as well as disturbance.

Activities during the operation phase of the Project such as open pit quarrying, dewatering, water treatment and release and waste rock disposal may result in alteration to wetland hydrology in adjacent wetlands.

Project-related groundwater collection may affect the hydrology in adjacent wetlands in particular wetlands that rely on groundwater discharge to maintain hydrology. This is unlikely to affect wetlands located within the Study Area, however, as these wetlands are largely precipitation driven and/or associated with surface water features such as lakes and streams; as such they do not necessarily rely solely or primarily on groundwater inputs.

The unmanaged use of road salt for winter safety may adversely affect vegetation and water quality in wetlands. Road salt is a toxic substance, controlled under the *Canadian Environmental Protection Act* (CEPA), and can harm wildlife if overused. Road salt runoff can

influence vegetation species composition in wetlands, though the affected area would be very small.

Fugitive dust and sediment runoff generated from road traffic during operation are not likely to adversely affect wetlands, since the amount of material lost is expected to be very small. Dust originating from quarrying and rock crushing may land on native vegetation and interfere with plant respiration, but this effect is expected to be limited in time and space and will be mitigated by natural precipitation events that wash dust onto the soil. Dust may also deposit minerals and nutrients in the wetlands.

The potential for introduction of invasive species carried on vehicles operated on roads is much lower during operation, since disturbed wetland soils will be re-vegetated. During maintenance of the power line right-of-way, the potential for introducing invasive species would be similar to construction.

During the operation phase, wildlife in wetlands may be disturbed by noise and lights from the Quarry operation. Potential impacts on terrestrial fauna are described in Section 7.9, below.

Similarly to the construction phase, wetlands in close proximity to the Project footprint may be adversely affected if accidental spills of deleterious substances such as fuels, lubricants or engine oil occur. Downstream wetlands cannot be affected by a failure in the sediment pond containment system since sedimentation ponds and pit sumps will be located within back-graded work areas; they may flood but they will not overflow.

7.8.3.3 Decommissioning

The effects of Project activities during the construction and the decommissioning phase are similar.

7.8.4 Mitigation and Monitoring

Mitigation measures are outlined below for each potential adverse effect. Mitigation measures developed for the protection of surface water quality will also protect wetlands (Sections 7.6). The potential effects of spills, malfunctions and accidents and recommended mitigation measures are discussed in Section 7.18. A wetland specific monitoring program will be implemented immediately post-construction to confirm the predictions of the environmental assessment and to identify any unforeseen wetland impacts.

To reduce disturbance and eliminate loss of wetland function in directly impacted wetlands:

- Wetland areas will be avoided to the extent feasible during Project design and planning.
- Where wetlands cannot be completely avoided, the Project footprint in the wetland area will be minimised to the extent possible.
- A wetland alteration permit will be obtained from NSE prior to construction.
- Wetland functions have been assessed for all potentially disturbed wetlands and the amount and type of functions lost (if any) will be determined.
- Where a permanent loss of wetland function is identified, a Compensation Plan will be developed, subject to approval by NSE.

To prevent impacts on wetland hydrology:

- Maintain a 30 m buffer around all undisturbed wetlands.
- Where the access road cuts across diffuse natural drainage paths, water conveyance structures of sufficient size (culverts or drainage swales) will be installed to maintain water flow to and from wetlands at pre-construction levels.
- To the extent feasible, clean site runoff will be managed so that the amount of water entering adjacent wetlands is similar to pre-construction levels.
- Runoff collected along the roads will not be allowed to enter directly into wetlands, but shall be directed into vegetation buffers around wetlands.
- Integration of existing/remnant wetlands into the quarry's stormwater management system will be considered in the Stormwater Management Plan and in the EMP.
- The monitoring program enacted under the Wetland Compensation Plan will identify vegetation changes or new formation of wet areas within and adjacent to the Project site. This would be a sign of a disrupted hydrologic regime and further investigated to determine the need for management adjustments.

To prevent impacts on wetlands from erosion/sedimentation or dust:

- General erosion and sediment control measures will be established in the Project EMP and implemented on site to prevent or minimize erosion and subsequent site runoff into nearby wetlands and surface waters while soils are exposed and de-stabilized.
- Prior to construction, a site-specific erosion and sediment control plan will be developed, including a description of the proper installation of silt fences and cofferdams.
- Uncontaminated drainage will be directed away from areas under construction.
- Ground disturbance will be kept to a minimum and standard erosion control measures will be implemented for disturbed areas as needed.
- Dust control will be established in the Project EMP.
- Efficacy of the erosion and sediment control measures will be monitored regularly and when high precipitation events are forecast.

To prevent impacts on wetland habitat from contaminated runoff:

- Vegetation management in or near wetlands will be conducted by cutting (i.e., no use of herbicides).
- Potentially contaminated site runoff will be directed to the on-site wastewater treatment system.

7.8.5 Residual Effects & Significance

Project related activities are not likely to result in significant residual adverse impacts on wetland habitats after the successful implementation of the identified mitigation measures, including compensation. Table 7.8-2 provides a summary of the effects assessment.

**Table 7.8-2:
Residual Environmental Effects for Wetlands**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Wetland removal or loss of wetland functions as a result of infilling and development activities.	A	See Mitigation Section	1	2	5/6	I	1	Habitat loss / Wetland compensation	Not Signif.
Alteration of wetland hydrology.	A	See Mitigation Section	1	2	5/6	I	1	Habitat loss	Not Signif.
Alteration of water quality from sediments and dust.	A	See Mitigation Section	1	2	5/1	R	1	Habitat loss	Not Signif.
Reduction in wetland functionality due to the introduction of invasive species.	A	See Mitigation Section	1	2	5/1	R	1	Habitat loss	Not Signif.
Impacts from contaminated site runoff and vegetation management.	A	See Mitigation Section	1	1	5/1	R	1	Habitat loss	Not Signif.

Legend

Magnitude:

U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.
0 = Nil - No environmental effect.
1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)
2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)
3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)

Geographic Extent:

1 = < 1 km²
2 = 1 – 10 km²
3 = 11 – 100 km²
4 = 101 – 1,000 km²
5 = 1,001 – 10,000 km²
Duration:
1 = < 1 month
2 = 1 – 12 months
3 = 13 – 36 months
4 = 37 – 72 months
5 = > 72 months

Frequency:

1 = < 11 events/year
2 = 11 – 50 events/year
3 = 51 – 100 events/year
4 = 101 – 200 events/year
5 = > 200 events/year
6 = continuous

Reversibility:

R = Reversible
I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.
2 = Evidence of adverse environmental effects.

N/A = Not applicable
A = Adverse
P = Positive

7.9 TERRESTRIAL WILDLIFE

Terrestrial fauna have ecological, aesthetic and recreational importance to the public and the Mi'kmaq as a food source and as an economic and recreational resource. Project development will diminish or eliminate the productive capacity of some terrestrial habitat within the Project footprint. Other indirect interactions (airborne dust, emissions, noise, vibration, light, water extraction, and consumption) may affect species and habitat within the area of influence of the Project. Most terrestrial species and habitat are regulated by the Province. Migratory bird species are regulated at the Federal level.

A discussion of potential impacts of the construction, operation and decommissioning phases of the Project on common terrestrial fauna is presented below.

7.9.1 *Boundaries*

Spatial boundaries establish the limits within which the Project interacts with the surrounding environment. The area of influence reflects an area beyond the Project footprint and incorporates aspects such as airborne plumes which can act to expand the physical area over which Project features interact with the receiving environment.

The spatial ecological boundaries for terrestrial wildlife include all undeveloped environments within the footprint of the Project, as well as all undeveloped environments within 500 m of the Project site and the shipping lanes offshore in habitats utilized by marine-associated bird species (including seabirds, waterfowl and shorebirds). This buffer is considered to be the maximum extent to which noticeable effects on birds, wildlife and SAR can be reasonably expected as a result of Project components and activities.

Temporal ecological boundaries encompass the entire year, since interactions between terrestrial fauna and Project components or activities can occur year round. This applies to every year of all phases of the Project. For terrestrial fauna, the breeding season is of particular concern. The breeding season for most migratory bird species in the region is between early April and the end of August (EC 2014f), although some migratory species nest outside of this timeframe. Owls, raptors and woodpeckers generally breed earlier in the season from late winter to early spring (February to May). Most other wildlife breeds in spring and summer.

With respect to the administrative and legislative boundaries, the federal the *Migratory Birds Convention Act* (MBCA) is an important regulatory mechanism to protect birds. At the provincial level, The NSDNR administers the Nova Scotia Wildlife Act (NSWA) which provides mechanisms for the preservation of wildlife species diversity and abundance, including migratory birds. Further protection of habitats that are critical to migratory birds and other wildlife species is provided by the federal *Canada Wildlife Act* and its regulations, which are administered by EC. Legal protection is offered to species that have been proclaimed as endangered, threatened or special concern under the federal SARA, and to species proclaimed as endangered, threatened or vulnerable under the NSESA.

7.9.2 *Threshold for Determination of Significance*

A significant adverse effect of Project components or activities on terrestrial fauna is defined as an effect that causes a decline in abundance and/ or a change in distribution beyond which

natural recruitment (reproduction and immigration from unaffected areas) would not return the population to its pre-project level within several (three to five) generations⁷. An adverse effect that does not cause such declines or changes is not considered to be significant in most instances. However, mortality of a single individual of a Species at Risk or a large number of migratory birds or other fauna could also be considered a significant adverse environmental effect.

Effects on critical habitat of a migratory bird SAR which cause breeding failure or abandonment of nesting may also be considered significant, even if the effects are temporary. This would include abandonment or nesting failure of a migratory bird SAR or at a seabird/waterbird colony due to an accidental event or the response to an accidental event associated with the Project.

7.9.3 Effects on Birds and Other Terrestrial Fauna

A discussion of potential impacts of the construction, operation and decommissioning phases of the Project on terrestrial fauna is presented below. Since the potential effects and mitigation for most avian SAR and SOCC is identical to non-SAR birds, they have been included in this discussion. Other SAR is addressed in Section 7.12.

7.9.3.1 Construction

Landbirds

The main impact on landbirds will be the loss of nesting and foraging habitat. Vegetation clearing and grubbing activities may also cause destruction of nests and nestlings or eggs if conducted during the breeding season (early April to end of August; EC 2014f).). Breeding evidence has been observed for several avian species within the Project footprint, including seven priority species with a Canadian General Status ranking of "Sensitive": Bay-breasted Warbler, Black-backed Woodpecker, Blackpoll Warbler, Boreal Chickadee, Golden-crowned Kinglet, Ruby-crowned Kinglet, and Yellow-bellied Flycatcher. Up to 213 ha of terrestrial bird habitat may be removed. Habitat within the Project area consists mostly of barren vegetation, tall shrub barren, and some coniferous forest, with patches of mixed forest and wetlands; 22 wetlands totaling approximately 57 hectares were delineated within and adjacent to the Project site.

In addition to habitat loss, construction noise (including blasting) may have deleterious effects on animals in and near the Project area. Flushing of nesting birds may result in decreased productivity due to increased nest predation and stress to adult birds affecting foraging behaviour (Beale 2007); as well, birds may leave the Project area and be forced to move to less favourable nesting sites (Larkin 1996). The data regarding effective distance due to noise disturbance are relatively few and conflicting, with various field studies showing effects from edge of area of disturbance to 200 m. Construction noise can interfere with normal bird behaviour, such as feeding, migrating, and breeding. The distance of effect is of course related to noise volume and quality. Blasting noise is a type of impulse noise, which is defined as a sound with sudden onset and typically a short duration, and which differs from continuous noise in its physiological and behavioural effects on wildlife (Larkin 1996). In terms of behavioural

⁷ This definition of significance does not apply to species of conservation concern, which are treated separately in Section 7.12.

effects, flushing of breeding birds from the nest in response to impulse noise and/or vibration is perhaps the most obvious and can have immediate negative consequences including predation of eggs and chicks (e.g., Burger 1981; Brown 1990; Bolduc and Guillemette 2003) and decreased incubation and brooding (Burger *et al.* 2010; Beale 2007). As well, young nestlings that are unable to thermoregulate may be vulnerable to exposure, and adults may inadvertently knock eggs and flightless young from the nest, which is of particular concern for cliff- and tree-nesting species (Burger 1981; Carney and Sydeman 1999). Research has shown that for birds, overt behavioural responses such as flushing typically occur at sound pressure levels above 80 - 85 dB SPL (sound pressure level) (Brown 1990).

Negative effects from noise vary from species to species, because of interspecies differences in both hearing abilities and in behavioural and physiological responses to stimuli. In addition to interspecies differences, there is considerable intraspecies variation in vulnerability to effects of noise, for example in different times of year (i.e., different stages of the breeding cycle) and different life stages (Blumstein *et al.* 2005). The effects of noise on the site due to construction are expected to be temporary and short-term.

Shorebirds

Disturbance due to construction noise (including blasting) is expected to have minor impacts on breeding, migrating and/or wintering shorebirds, depending on when the activities take place. Increased sedimentation from dust generated by construction, as well as changes to hydrology of Fogherty Lake, could potentially result in habitat alteration or habitat loss for shorebird species that could potentially be nesting in the area, such as Greater Yellowlegs and Spotted Sandpiper; however, no evidence of breeding shorebirds was reported during the field surveys.

Seabirds and Waterfowl

Waterfowl along the marine shoreline and inland ponds and lakes may be disturbed by noise from blasting and other construction activities, but these effects are likely to be temporary and minor. Waterfowl and loons are unlikely to nest in Fogherty Lake because of its low pH and low productivity; therefore, they are not anticipated to be negatively affected by habitat loss or alterations in water supply to the lake.

Seabirds nest on a number of offshore islands and other inaccessible coastal areas, notably the Country Island Complex. A large tern colony supporting a significant number of breeding Roseate Terns exists in the Country Island Complex IBA; however, the nearest point of this IBA is 13 km away, and Country Island itself (which supports the largest number of Roseate Terns as well as a significant colony of Leach's Storm-Petrel) is approximately 40 km away, which is sufficiently far from the Project area that no disturbance at the colony is anticipated. Minor disturbance of foraging terns from blasting and other construction noise is possible; however, the distance from the colony is such that it is unlikely that Roseate Terns will forage in the waters near the Project area. Large gulls and Common and Arctic Terns nesting on Fox Island and Half Island, both approximately 3 km from the Project site, could potentially be disturbed by blasting noise. However, this distance is greater than the 1 km buffer recommended by EC for high-disturbance activities including drilling and blasting (EC 2014).

Mammals

Habitat removal and fragmentation will result in displacement of wildlife within the Project footprint. Species that can move easily will likely move to similar habitats elsewhere, if such habitat is available; however, ultimately, there will be a detrimental effect on terrestrial wildlife populations within the Project area. These effects will be non-reversible for the duration of the Project lifetime. During construction activities, temporary and reversible effects from noise (including blasting) and dust generation may also affect terrestrial wildlife in and around the Project area. Potential effects on terrestrial fauna SAR and species of conservation concern are described in Section 7.12.

A number of furbearers have potential to occur in the Project area, and habitat removal and disturbance due to human activities may result in some or all of these species being extirpated from the area. Impacts on other mammals are also expected to be mainly related to loss and fragmentation of habitat.

Clearing and construction activities are expected to slightly reduce the available area used by terrestrial mammals and interrupt local movement to and from adjacent areas of suitable habitat. Project related noise (including blasting) may cause mammals in immediately adjacent areas to flee temporarily. The furbearers and other mammals in the local area may temporarily move elsewhere during the construction period. Local populations are likely to return to normal after construction is complete.

Mammal species with special status such as moose, fisher, and bats may occur in the Project area. Potential for impacts on such species are presented in Section 7.12.

Herpetiles

The loss of ponds, wetlands and riparian areas in the Project area will result in habitat loss for local amphibians and for turtles, and increased sedimentation from dust generated by construction may further impact aquatic habitats. Snakes may utilize much of the Project area, and will be impacted by habitat loss as well as increased fragmentation which may inhibit movement between areas of suitable habitat.

Invertebrates

Some loss of odonate (dragonfly and damselfly) breeding and feeding habitat is expected from the loss of wetlands, ponds and riparian areas within the Project area. Dust from construction activities may contribute to sediment loading in watercourses, potentially altering aquatic habitats. Lepidopterans (moths and butterflies) will be most affected by the loss of larval food plants, which varies from species to species; adults are highly mobile and therefore able to avoid areas impacted by Project activities.

7.9.3.2 Operation

Landbirds

Increased human activity associated with the operation phase is expected to result in an increase in populations of species that are adapted to human environments, including European Starlings, American Robins, Common Grackles and Rock Pigeons; these species may compete

with native woodland and forest edge birds, resulting in habitat loss for these species less adapted to human presence. Potential effects of blasting noise are the same as for the Construction phase.

The Project area will of necessity be well-lit with high intensity lighting at night, and although the lighting will be directed as narrowly as possible by shielding, these lights may have disorienting effects upon migrating landbirds, particularly on foggy and overcast nights, causing potentially fatal collisions.

Shorebirds

Potential effects of blasting noise are the same as for the Construction phase. The presence of sedimentation ponds on the site may provide some marginal habitat for shorebirds, although the high level of human activity makes it unlikely that these ponds will be utilized during the operations phase. Increased human activity around the marine terminal and load-out facility will result in increased disturbance to fauna in the surrounding coastal environment, including shorebirds that may feed in the area. Marine traffic associated with the quarry (an estimated 2 ships per week) will travel within existing domestic commercial shipping lanes, which pass to the south of the South Shore (Port Joli sector) IBA. This IBA supports breeding Piping Plovers in the summer and large numbers of migrating shorebirds in the fall months. While day-to-day shipping activities are unlikely to have any impact on shorebirds at the South Shore (Port Joli sector) IBA, accidental spills and releases from marine traffic could result in the direct physical exposure of birds to oil within the affected area; effects of accidents and malfunctions are discussed in Section 7.18.

Waterfowl and Seabirds

Potential effects of blasting noise are the same as for the Construction phase. The presence of sedimentation ponds on the site may provide some marginal habitat for waterfowl, although the high level of human activity makes it unlikely that these ponds will be utilized during the operations phase.

Increased shipping activity associated with the Project (an estimated 2 ships per week) will cause disturbance to seabirds and waterfowl in the waters off the Project site and along shipping routes. The possible effects of marine vessel traffic on birds in the offshore environment include behavioural changes (e.g., avoidance, stress response) that may have energetic consequences (Schummer and Eddleman 2003), and loss of suitable feeding habitat as vessel traffic can reduce bird use of vessel disturbed areas (Bramford *et al.* 1990), although this is mitigated by utilizing existing shipping lanes for most of the shipping route. Increased vessel traffic is not anticipated to cause disturbance at the Country Island Complex and South Shore (Port Joli sector) Important Bird Areas; however, foraging seabirds from these sites may encounter minor disturbance, and accidental spills and releases from marine traffic could result in the direct physical exposure of birds to oil within the affected area, with possible lethal and sublethal effects; effects of accidents and malfunctions are discussed in Section 10.17.

Mammals

Potential effects of the operation phase of the Project are anticipated from increased noise (including blasting) and disturbance from traffic and other human activities at the quarry. Local nocturnal species may be attracted to and/or disoriented by changes in ambient lighting.

Project operation may cause changes in the diversity and relative abundance of local mammal populations, such as potential increase in red fox, raccoon and striped skunk that are well adapted to human presence. This effect could be exacerbated if good housekeeping practices are not maintained on-site.

Herpetiles

No additional impacts on snakes are expected during the operation phase; additional impacts on turtles and amphibians may occur if water levels or surface water drainage patterns were to change, and/or if there is a change in water quality from operational procedures.

Invertebrates

No additional impacts on odonates and butterflies are expected during the operation phase. Moths may be attracted to new artificial lighting on the Project site, increasing the risk of predation.

7.9.3.3 Decommissioning

During decommissioning, increased human activity, noise and dust are expected to have temporary negative effects on local terrestrial wildlife populations (including birds). Local populations are expected to return to normal following decommissioning activities.

The lifespan of the quarry is anticipated to be 50 years or more. Impacts during decommissioning are expected to be similar to construction but of much shorter duration. The condition of the site after decommissioning will depend on the future use by the next owner or the municipality. Given that the Project location is relatively isolated, it is likely that the site will be rehabilitated to a natural state upon decommissioning. There is potential for new types of habitats, such as ponds and rocky cliffs, to remain on the site upon decommissioning.

7.9.4 Mitigation & Monitoring

Generic mitigation measures related to terrestrial fauna are listed below. For specifics mitigation measures related to terrestrial SAR and SOCC, please refer to Section 7.12. Mitigation for potential impacts on marine-associated birds from shipping is identical to other marine fauna, as described in Section 7.11.

Mitigation measures for potential impacts during decommissioning are similar to those outlined for the construction phase. Decommissioning activities will be carried out in accordance with all applicable regulatory requirements at the time, and a decommissioning plan will be developed.

During Construction:

- Reduce Project footprint and temporary work areas to the extent possible.
- Clearing of vegetation and overburden should be restricted to areas absolutely necessary to carry out the Project.
- Implement dust-prevention and dust abatement measures.
- Workers should be instructed to maintain good housekeeping practices and not leave any food or garbage at the Project site in order to avoid attracting wildlife, including

omnivorous predators which may disturb or cause direct mortality or injury to other wildlife (including birds).

- Mitigation measures are particularly important during the avian breeding season when nest failure could result if incubating adults are repeatedly flushed from active nests. To minimize impacts on nesting landbirds, clearing activities will take place outside of the breeding season for most bird species (April 1 to September 1) to prevent the disturbance of migratory birds or their nests. If some clearing is necessary during the breeding season the Proponent will assess if the work can be conducted without contravention of the *Migratory Birds Convention Act* and a contingency plan developed in consultation with CWS in order to maintain compliance with the *Act*. With implementation of these mitigation measures, significant adverse residual effects on birds are not likely.
- If an Osprey, Bald Eagle or Northern Goshawk nest is found within the forested areas to be cleared, even outside of the breeding season, a buffer zone appropriate to the species (as determined in consultation with NSDNR) will be placed around the nest and clearing will only occur outside of the buffer zone.
- To discourage ground-nesting or burrow-nesting species from nesting on disturbed soil during construction (e.g. Bank Swallow or Common Nighthawk), ensure that no large piles or patches of bare soil are left uncovered or un-vegetated during the breeding season.

Should any ground- or burrow-nesting species (e.g. Bank Swallow or Common Nighthawk) initiate breeding activities on stockpiles or exposed areas despite efforts to deter them, the Proponent will establish a 20 m buffer around the nest location once identified and contact EC-CWS for further advice. Potentially disruptive activities such as use of machinery, disposal of additional material, removal of material and stabilization measures (e.g., hydroseeding) will be halted within the buffer area, non-disruptive measures will be taken to reduce potential for erosion of the pile, and the nest(s) will be protected. Periodic monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area and the nest site is found to be inactive.

- Noise suppression equipment such as mufflers on mobile equipment and fixed/portable engines will be maintained in original OEM working condition.
- The duration of noise disturbance should be minimized.
- Lighting should be restricted to areas where it is necessary.
- To minimize interference of nesting activities from noise and human presence, workers will be encouraged to refrain from entering surrounding undisturbed habitat areas where no work is done, as those areas likely hold the largest number of birds.
- In the event that impacts on migratory birds are detected during construction, further mitigation will be developed in consultation with NSDNR and EC.

During Operation:

- Standard mitigation measures for noise (including blasting), as outlined in Section 7.2, will minimize impacts on terrestrial fauna.
- To discourage ground-nesting or burrow-nesting species from nesting on disturbed soil during construction, ensure that no large piles or patches of bare soil are left uncovered or un-vegetated during the breeding season.

Should any ground- or burrow-nesting species (e.g. Bank Swallow or Common Nighthawk) initiate breeding activities on stockpiles or exposed areas on site despite efforts to deter them, the Proponent will establish a 20 m buffer around the nest location once identified, and contact EC-CWS for further advice. Potentially disruptive activities such as hydroseeding will be halted within the buffer area, non-disruptive measures will be taken to reduce potential for erosion of the pile, and the nest(s) will be protected. Periodic monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area and the nest site is found to be inactive.

- As recommended by EC (2014c; 2014e), ships should maintain a minimum distance of at least 300 m from any colony or island occupied by seabirds and waterbirds.
- To minimize the risk to migrant birds, the minimum amount of pilot warning and obstruction avoidance lighting will be used on tall structures. The use of solid-burning or slow pulsing warning lights at night will be avoided.
- A detailed avian management plan (including monitoring program) will be developed in consultation with EC-CWS in order to verify the effectiveness of mitigation measures related to lighting.
- Lighting for the safety of the employees should be shielded to shine down and only to where it is needed, without compromising safety.
- Street and parking lot lighting should also be shielded so that little escapes into the sky and it falls where it is required. LED lighting fixtures are generally less prone to light trespass and should be considered.
- Should seabirds or other species become stranded on vessels or on land, the proponent is expected to adhere to appropriate handling protocols. The protocol "*Best practices for stranded birds encountered offshore Atlantic Canada*" (EC 2014e) will be used for stranded seabirds. The proponent should also consider developing a similar-type protocol for birds other than seabirds (e.g. landbirds, shorebirds) which may become stranded on vessels. A permit is required to implement the Williams and Chardine protocol or other similar protocols, as well as to handle migratory bird carcasses during post-construction monitoring programs. Proponents should be advised that they are required to complete a permit application form prior to proposed activities. Permit application forms can be obtained by contacting Canadian Wildlife Service (email: Permi.atl@ec.gc.ca).
- White lights will be preferred for use on towers or high structures at night, as recommended by the US Fish and Wildlife Service (2003). Solid red or flashing red lights will be avoided as they appear to attract nocturnal migrants more than white flashing lights (US Fish and Wildlife Service 2003).
- Unless safety is a factor, the use of exterior decorative lights such as spotlights and floodlights, whose function is to highlight features of buildings or to illuminate an entire building, will be avoided or restricted because their glow can draw birds from far away, particularly on humid, foggy or rainy nights.
- High intensity lights, including floodlights, will be turned off at night outside of working hours, if possible, especially during the spring and fall migration period.
- Where feasible, tinted or frosted glass windows will be used in buildings to reduce bird mortality from collisions, as recommended by Erickson et al. 2005.

During Decommissioning:

Mitigation measures for potential impacts during decommissioning are similar to those outlined for the construction phase. Decommissioning activities will be carried out in accordance with all applicable regulatory requirements at the time and a decommissioning plan will be developed. The decommissioning plan will include a detailed rehabilitation plan. As part of the rehabilitation, the proponent is committed to implement specific habitat enhancement measures that maximize terrestrial and freshwater habitat diversity and quality.

7.9.5 Residual Effects & Significance

Table 7.9-1 provides a summary of recommended mitigation measures and residual environmental effects after successful implementation of the above mitigation measures.

With the successful implementation of these mitigation measures, Project activities related to construction, operation and decommissioning of Project components are not likely to result in significant adverse residual adverse effects on terrestrial fauna, excluding SAR, which are discussed in Section 7.12.

**Table 7.9-1:
Residual Environmental Effects for Terrestrial Fauna**

7.10 FRESHWATER SPECIES AND HABITATS

Fish and fish habitat are valued for their ecological services as a renewable resource base, and for their economic, cultural, spiritual and ceremonial benefits. The watercourses and lakes on the Property do not contain fish due to acidic conditions. Nevertheless, other freshwater species and habitat are important biological components of larger ecological systems and are valued by the public and the Mi'kmaw. Project activities will remove some freshwater environment and may indirectly affect other areas. After quarrying ceases and the pit fills with water, the Project will ultimately create more freshwater habitat than currently exists on the site.

As described in Section 6.5, the freshwater environment within the Property boundary includes one waterbody, Fogherty Lake, and three watercourses. No fish were captured in Fogherty Lake or any of the watercourses during fish collection events. The field measured pH level in Fogherty Lake was 2.9 and in the watercourses pH levels ranged from 2.9 to 3.4. Based on the highly acidic conditions in freshwater environments, these water bodies do not support fish species (Robertson and Bryan 2004).

The majority of the effects to the freshwater environment are associated with the construction and operation of the quarry. The construction of quarry infrastructure is not anticipated to result in the removal of freshwater environments; one watercourse (Watercourse 2, which is ephemeral) will be lost during the operation of the quarry.

7.10.1 Effects Mechanics

Table 7.10.1 lists the probable interactions between the Project and Freshwater Species and Habitats.

**Table 7.10-1:
Project Interactions with Freshwater Species and Habitats**

Project Phase	Duration	Relevant Project Works and Activities
Construction Phase	2-3 Years	<ul style="list-style-type: none"> • Site Clearing, Grubbing grading in preparation of construction • Watercourse and wetland alteration • Surface water discharge
Operations Phase	50 years	<ul style="list-style-type: none"> • Domestic wash water supply: potential groundwater – surface water interaction • Rock removal (quarrying) that results in alterations in surface and groundwater flow patterns and water supply to down-gradient watercourses. • Storm water and wash water management and surface water discharge
Closure and Rehabilitation Phase	2+ Years	<ul style="list-style-type: none"> • Rehabilitation of the quarry

7.10.2 Boundaries

7.10.2.1 Temporal Boundaries

As noted, effects to Freshwater Species and Habitats are primarily associated with the Operations Phase, but may also occur during construction and during Closure and Rehabilitation.

7.10.2.2 Spatial Boundaries

Assessment boundaries have been characterized as the Project Area (PA), Affected Area (AA), and Study Area (SA).

The Project Area is defined as the freshwater environment within the Project Property boundary. This includes three watercourses (Watercourse 1, ephemeral Watercourse 2 and Watercourse 3) and Fogherty Lake, but excludes wetlands since wetlands are described in a dedicated chapter of the EIS (Section 7.8).

The Affected Area is the zone around the Property which could be affected by Project components or activities. With respect to Freshwater Species and Habitats, this will include all down-gradient freshwater ecological receptors that currently receive surface and groundwater flow from portions of the Property that will be developed for the quarry, since changes to water flow may negatively affect these receptors. It also includes areas immediately adjacent to the Property boundary where dust from quarrying activities may be expected to fall. Within this Area is Murphy's Lake. Given the acidic conditions measured at the lake outlet, Murphy's Lake likely does not directly support fish and fish habitat.

Outside of these zones, no additional Project-environment interactions are expected with respect to the Freshwater Species and Habitat VC.

7.10.2.3 Relevant Legislation

The federal Fisheries Act (Section 35) is the primary piece of legislation in Canada governing the protection, conservation and management of fish and fish habitat. This act is enforced by Fisheries and Oceans Canada. The Act prohibits serious harm to fish that are part of or support a commercial, recreational, or Aboriginal (CRA) fishery. Harm can be caused by proposed works, undertakings or activities that affect fish habitat, passage of fish or modify flow in watercourses. If serious harm to fish that is part of or support commercial, recreational or Aboriginal fisheries will occur as the result of a proposed undertaking, the proponent is required to prepare a habitat off-set plan and obtain an authorization under the Fisheries Act 35(2)(b) prior to commencing works.

7.10.2.4 Technical Boundaries

No technical boundaries were identified for this VC.

7.10.3 Threshold for Determination of Significance

Methods describing the spatial and temporal effects of the project activities and works on Freshwater Species and Habitat are described below. Presence and absence of fish and fish

habitat was determined through a sampling program described in Section 6.5. To the extent possible potential effects of the project on Freshwater Species and Habitat were quantified. These effects include:

- Direct removal of water bodies: assessed by querying the data layers with the anticipated disturbance areas within the Project boundaries. The amount (ha) of water body and length (m) of watercourses anticipated to be removed was tallied within the Project property boundaries.
- Indirect effects from changes in surface water quantity and quality: assessed based on results from available hydrologic modeling and the surface water quality assessment.

Relevant results from the terrestrial habitat assessment were integrated with the results from the fish and fish habitat assessment (i.e., effects on Freshwater Species and Habitat were cross-referenced with the effects on wildlife and wetlands and riparian habitat).

With respect to this VC, a significant effect is defined as a permanent, irreplaceable loss of Freshwater Species and Habitat that are part of or support a commercial, recreational or Aboriginal fishery.

7.10.4 Effects on Freshwater Environment

No freshwater fish or fish habitat occurs within the Project Area due to unsuitable acidic conditions observed in waterbodies and watercourses. Given this, Project activities will not result in negative effects to fish and fish habitat in these water bodies and watercourses. This is consistent with the highest objective in the planning hierarchy through the principle of avoidance.

The southern portion of the Property is situated within part of the surface water catchment of Reynolds Brook, located in the Affected Area approximately 1.0 km south of the site, immediately south of Route 16. For the purposes of the EIS, Reynolds Brook is assumed to support fish at some point between the headwaters wetland to the east and downstream Hendsbee Lake located approximately 3.0 km to the west. At full quarry build out after approximately 50 years of operation, approximately 106 ha of the Property which formerly drained south to Reynolds Brook will be diverted into the quarry pit for ultimate discharge north into Chedabucto Bay. This represents approximately 18% of the Reynolds Brook catchment above Hendsbee Lake, which totals 578.5 ha at the lake inflow. This eventual permanent reduction in flow may have negative effects on fish and fish habitat in Reynolds Brook during dry periods. Alternatively, the reduction of low pH inflows to Reynolds Brook from the Property may in fact improve water quality and promote higher quality fish habitat than is currently present.

In the absence of fish and fish habitat on the site, the following discussion relates to Project impacts on the freshwater environment including necessary watercourse removals, and crossings to Watercourse 2 and 3.

The next step in the environmental assessment process involves evaluating potential residual adverse environmental effects by Project phase. The evaluation of environmental effects, including cumulative environmental effects, included:

- The potential interaction between Project activities, for each Project phase, and their environmental effects in combination with those of other likely future projects;

- The mitigation strategies applicable to each of the interactions; and
- Evaluation criteria for characterizing the nature and extent of the environmental effects.

Environmental effects assessment matrices have been used to summarize the analysis of environmental effects, including cumulative environmental effects, by Project phase and include accidents, malfunctions and unplanned events. This allows for a comprehensive analysis of all Project-VC interactions. Supporting discussion in the accompanying text highlights particularly important relationships, data or assessment analyses results.

Projects effects are summarized in Table 7.10-2.

**Table 7.10-2:
Project Interactions by Project Phase**

Project Works and Activities	Interaction with VC (Yes / No)	Rationale
Site Preparation Phase		
Site Clearing, Grubbing and Pre-stripping	Yes	Site clearing, grubbing and pre-stripping will alter riparian habitat and may increase erosion and runoff to surface water bodies. These factors will increase the risk of sedimentation and may affect water quality in turn affecting this VC.
Topsoil and Overburden Stripping and Stockpiling	Yes	Surface water quality may be altered through erosion and runoff, which in turn may affect Freshwater Species and Habitats.
Construction of Enabling Infrastructure (i.e., offices, roads, electrical transmission lines and substation, process water supply system, sewage treatment system)	Yes	Construction of roads may require watercourse crossings and culvert installations (loss of habitat).
Construction of the Processing Plant (e.g. crusher, conveyor, plant facilities)	Yes	Construction of plant area components will alter drainage patterns, and may affect surface water quality.
Operations Phase		
Operations and Maintenance of Enabling Infrastructure (i.e., domestic water supply, sewage treatment and disposal, project roads)	Yes	Discharge of surface water may alter surface water quality which in turn may negatively affect Freshwater Species and Habitats. Operation and maintenance of roads may reduce water quality along roadways and affect this VC downstream of roadways.

Project Works and Activities	Interaction with VC (Yes / No)	Rationale
Pit development	Yes	<p>Blasting residue may impair water quality and cause harm to Freshwater Species and Habitats. Removal of rock will alter surface and groundwater flow patterns and may reduce surface flows to downstream water bodies thereby negatively impacting Freshwater Species and Habitats.</p> <p>Full quarry development will reduce Reynolds Brook inflows by approximately 18%. This may impair fish survival during dry periods and/or improve habitat quality by reducing inflows of low pH surface water.</p>
Closure and Rehabilitation Phase		
Final Rehabilitation of Quarry	Yes	<p>Final rehabilitation and creation of the "Pit Lake" will create more freshwater habitat than will be lost during Project Operation. This will present opportunities for the creation of fish habitat and wetlands.</p>

Construction and Operation

The construction of the open pit quarry will result in the loosening of vegetation, drilling and blasting to establish benches, roads, and stormwater management facilities. Stockpiling of overburden will also occur within the property area. Potable water will be supplied by drilled groundwater wells or bottled water.

The effects to freshwater environments as a result of the construction of access roads have largely been mitigated by design. The access roads will be a minimum of 30 m from waterbodies, including wetlands. A single watercourse crossing (Watercourse 3) will be required as a result of road construction. Best practices will be implemented into the design of the crossing to minimize effects to Freshwater Species and Habitat.

The primary effect of the quarry on Freshwater Habitats and Species will be indirect and due to changes in drainage patterns. As rock is removed through quarrying, surface and groundwater flow will be directed away from current freshwater habitats and into the pit. This altered flow will occur slowly over time as the quarry develops. For example, Watercourse 2 will not be affected until sometime after year 5 of pit development. By the end of year 10, drainage to Fogherty Lake and Murphy's Lake, as well as Reynolds Brook, will be affected by pit development. Complete removal of water bodies due to draw down effects is not anticipated.

Effects from stockpile runoff have been avoided with proper mitigation. Material will be stockpiled a minimum of 30 m from existing waterbodies and enclosed with perimeter silt fencing if warranted.

7.10.5 Mitigation and Monitoring

7.10.5.1 Mitigation

Although the waterbodies within and immediately adjacent to the property boundary (i.e., Fogherty and Murphys Lake) do not support fish, standard mitigation measures will be applied to prevent eroded sediment from reaching these water bodies, as well as Reynolds Brook, which is assumed to support fish.

- As described in the Erosion and Sediment Control Plan, erosion and sediment control measures will be implemented to ensure that discharge water quality meets all relevant regulatory standards prior to discharge to receiving environment.
- As described in the Stormwater Management Plan, stormwater will be collected in the pit and in ponds near the processing plant to ensure that uncontrolled runoff will not occur.
- Overburden stockpiles, fuel and chemical storage facilities, and construction equipment will be located a minimum of 30 m from any water body.
- Flagging tape will be used to delineate temporary work areas and control construction access near retained wetlands and water bodies to protect natural substrates and vegetation contributing to habitat and bank stability;
- An Emergency Response Spill Contingency Plan will be prepared to prevent and manage the effects of any malfunctions and accidents.

The primary mitigation measure for the loss of, or impact to, Freshwater Species and Habitat is the creation of a 30 ha lake when quarrying activities cease. This lake will be fed by surface precipitation and groundwater seepage, instead of receiving its primary water supply from the discharge of acidic wetlands. It is anticipated that water quality will be higher than that currently present in Fogherty and Murphy's Lake, and thus freshwater habitat may support fish and fish habitat.

7.10.5.2 Monitoring

Fish habitat assessment and a determination of fish presence/absence are proposed for Reynolds Brook above Hendsbee Lake. If fish are present in this reach, then a modest environmental effects monitoring program is proposed for such time as quarry development begins to divert water away from its natural drainage to the south. This is not expected to occur before year 10 of quarry development.

Within the site, monitoring will focus on verification of predicted effects and the effectiveness of mitigation. During construction and operation monitoring will focus on:

- Condition and location of erosion and sediment control intended to protect water features during soil stripping and grading and construction of site facilities;
- Water quality testing of stormwater discharges as outlined in the Surface Water Monitoring Program;
- Location and condition of fencing intended to protect sensitive retained features such as wetlands and water bodies to protect natural substrates and vegetation contributing to habitat and bank stability; and
- Ensuring overburden stockpiles, fuel and chemical storage facilities, and construction equipment are a minimum of 30 m from any water body.

7.10.6 Methodology for Determination of Significance

Potential effects of the project on the freshwater environment include changes in habitat suitability associated with physical habitat loss or alteration, and potential exposure to substances entering the water resulting from project activities. Effects are considered during construction, operation and decommissioning phases of the project. Effects are evaluated based on the definitions provided in Table 7.10-2 and presented in Table 7.10-3.

Given the existing freshwater environment, no significant adverse effects are likely to result due to project activities.

7.10.7 Residual Effects and Significance

Residual effects are evaluated after application of mitigation measures. These effects are assessed in the context of:

- Magnitude
- Geographic extent
- Duration
- Frequency

- Reversibility
- Ecological Context

Given the replacement of Freshwater Habitat and Species that will be undertaken at Project closure with the creation of the Pit Lake, no long term significant adverse residual effects to Freshwater Species and Habitat are anticipated as a result of Project activities.

**Table 7.10-3:
Residual Effects on the Freshwater Species and Habitat**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Loss of catchment area and altered flow in Murphy's Lake	A	See Mitigation Section	1	1	5/6	I	1	Minimal; likely not observable	Not Signif.
Increased freshwater fish habitat resulting from filling of pit post closure	P	See Mitigation Section	2	1	5/6	I	1	Positive – creation of new habitat	Not Signif.
Reduced flow to Reynolds Brook	Positive (Reduced flow of low pH water may increase pH of downstream water) or Adverse (during low flow periods)	See Mitigation Section	1	2	5/6	I	1	Reduced flow (18%) and/or improved water quality	Not Signif.

Legend

Magnitude:

U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.
0 = Nil - No environmental effect.

1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)

2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)

3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)

Geographic Extent:

1 = < 1 km²
2 = 1 – 10 km²
3 = 11 – 100 km²
4 = 101 – 1,000 km²
5 = 1,001 – 10,000 km²

Duration:

1 = < 1 month
2 = 1 – 12 months
3 = 13 – 36 months
4 = 37 – 72 months
5 = > 72 months

Frequency:

1 = < 11 events/year
2 = 11 – 50 events/year
3 = 51 – 100 events/year
4 = 101 – 200 events/year
5 = > 200 events/year
6 = continuous

Reversibility:

R = Reversible
I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.

2 = Evidence of adverse environmental effects.

N/A = Not applicable

A = Adverse

P = Positive

7.11 MARINE SPECIES AND HABITATS

7.11.1 Overview

Marine species and habitats are valued for their aesthetic, cultural, ecological and economic attributes by First Nations and the public at large. Marine SAR are of interest to scientists, regulators and public due to their inherent biological and cultural value and are protected under federal provincial legislation.

The majority of the effects to marine species and habitat are associated with the construction and operation of the marine terminal since the construction of this feature will remove marine habitat. Potential environmental effects on marine sediment quality are described in Section 7.4 while potential effects on marine water quality are described in Section 7.6.

The marine habitat in Chedabucto Bay supports productive and diverse fisheries. A number of fish species reside within the Bay, and additional species migrate from nearby water bodies such as the Strait of Canso and St. Georges Bay to feed or may potentially spawn (Gromack *et al* 2010). Marine mammals associated with Chedabucto Bay typically include seals, whales and porpoise. Potential environmental effects to commercial fisheries are described in Section 7.15. Potential environmental impacts to marine SAR are described in Section 7.12.

Table 7.11-1 lists the potential interactions between the Project and this VC.

**Table 7.11-1:
Project Interactions with Marine Species and Habitats**

Project Phase	Duration	Relevant Project Works and Activities
Construction Phase	2-3 Years	<ul style="list-style-type: none"> • Site clearing and grading prior to construction • Pile driving in the marine environment • Blasting in the terrestrial environment • Construction of marine terminal (caisson & rubble mound)
Operations Phase	50 years	<ul style="list-style-type: none"> • Stormwater and wash water management and use • Blasting in the terrestrial environment • Ship loading and marine vessel operations • Waste water treatment system discharge • Groundwater and surface water runoff, collection, treatment and discharge
Closure and Rehabilitation Phase	2 Years, may be extended	<ul style="list-style-type: none"> • Closure of marine terminal • Rehabilitation of the processing plant and quarry

7.11.2 Boundaries

7.11.2.1 Temporal Boundaries

Potential effects to the Marine Species and Habitats are expected to occur primarily during construction of the marine terminal, as well as during the Operations Phase when loading and shipping are ongoing. Additional effects may be felt in the marine environment during Closure and Rehabilitation, as the terminal is partially or completely dismantled.

7.11.2.2 *Spatial Boundaries*

Assessment boundaries have been delineated as the Project Area (PA), Affected Area (AA), and Study Area (SA).

With respect to the marine environment, the Project Area is defined as the limits of the proposed seabed Crown Lands Lease that will be needed for the marine terminal (Section 1.0 and **Figure 4.0-1**). The Crown lease extends approximately 300 m seaward and will entirely contain the marine terminal.

The Affected Area encloses the zone which could potentially be affected by Project components or activities and routes to the main shipping lanes in Chedabucto Bay (Figure 6.11-3). For this VC, the Affected Area includes the footprint of the marine terminal occupying approximately 0.4 ha in water up to 26 m deep and extending up to 120 m from shore. Cobbles dominate the substrate with boulder patches in the vicinity of the marine terminal footprint. The amount of marine flora decreases at depths greater than 25 m. The Affected Area extends 6.8 km from the marine terminal to the established shipping routes.

The Study Area is defined as the area considering all Project-environment interaction, including effects that may occur as a result of shipping between the marine terminal and established shipping routes. For the purpose of the Marine Species and Habitat, assessment of the Study Area is defined as the Canso Ledges EBSA to the mouth of Chedabucto Bay, considered a functioning marine ecosystem in *Ecological and Human Use Information for Twenty Areas on the Atlantic Coast of Nova Scotia in Support of Conservation Planning* (Gromack et al. 2010).

7.11.2.3 *Administrative Boundaries*

Fish and fish habitat in general are regulated by DFO at the federal level. The federal Fisheries Act (Section 35) is the primary legislation in Canada governing the protection, conservation and management of fish and fish habitat. This Act is enforced by Fisheries and Oceans Canada and prohibits serious harm to fish that are part of or support a commercial, recreational, or Aboriginal (CRA) fishery. Harm can be caused by proposed works, undertakings or activities that affect fish habitat, passage of fish or modify flow in watercourses. If serious harm to fish that is part of or support commercial, recreational or Aboriginal fisheries will occur as the result of a proposed undertaking, the proponent is required to prepare a habitat off-set plan and obtain an authorization under the Fisheries Act 35(2)(b) prior to commencing works.

Marine flora is a component of fish habitat and therefore is subject to regulations under the federal *Fisheries Act*. Sections of the *Fisheries Act* prohibiting the introduction of deleterious substances into marine waters are governed by EC. Protection of marine fauna is subject to the same regulations.

7.11.2.4 *Technical Boundaries*

No technical boundaries were identified for this VC.

7.11.3 *Threshold for Determination of Significance*

Methods describing the spatial and temporal effects of the Project activities and works on Marine Species and Habitat, including marine fish and fish habitat are described below.

Presence and absence of fish and fish habitat was determined through a sampling program described in Section 6.6. Quantity and quality of fish habitat was estimated using GIS tools. To the extent possible, potential effects of the Project on fish and fish habitat were quantified.

- Direct removal of marine habitat was assessed by querying the data layers with the anticipated disturbance areas within the Project Area and tallied.
- Indirect effects from changes in surface water quantity were assessed based on results from available surface water quality assessment.
- Effects to fish and fish habitat from the use of explosives near water, i.e. blasting.
- Effects to fish and fish habitat from in water vibrations associated with pile driving.

A significant adverse effect on the marine environment and biota is defined as one that is likely to cause:

- Adverse and irreversible changes to critical habitats;
- serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or to fish species that support such a fishery;
- permanent impairment of the ecological functioning of the biotic community; and/or
- increased ecological risk to a level that long term effects to the health of aquatic biota is predicted.

7.11.4 Effects on Marine Environment

As described in Section 3 (Project Description) the construction of the marine terminal will be based on a rubble mound approach with caissons installed to support the slewing or loading arm. Major components of the terminal will consist of:

- Rubble fill mound with an access road for maintenance
- Three breasting caissons.
- Two mooring dolphins.
- Eleven slewing rail piers, with piles installed in the seabed.
- One slewing rail caisson.
- Ship loader mounted on the slewing rail.

No refuelling facilities will be present.

There is limited information on coastal currents along the south shore of Chedabucto Bay in the Project area. Lawrence (1979) reports the results of five current meter moorings placed in Chedabucto Bay for 18 days in April 1970 following the *ARROW* oil spill. Mooring Station 3 was within several tens of meters from Black Point. The mean current amplitude in Chedabucto Bay was reported at 2.9 cm/sec with a large standard deviation (+/- 3.0). The extreme current minimum is 0.9 cm/sec while the extreme maximum was 11.5 cm/sec. Lawrence (1979) notes a tendency for anticlockwise flow at all three depth levels with a "strong topographic influence evident from directions at Station 3 near the southern coast" (i.e., near Black Point). He goes on to note "strong mean currents were recorded at Station 3".

Owens and Rashid (1976) described the south shore zone of Chedabucto Bay ranging from “sheltered, low-energy beaches composed of poorly sorted till-derived sediments, cobble and boulder beaches, to resistant rock cliffs directly exposed to the Atlantic Ocean.” In their discussion regarding the beach at Indian Cove (within Fox Bay immediately east of Black Point), they note “relatively little sediment is supplied to the littoral zone along this coast, due to the absence of till deposits along the shore zone, the resistant nature of the bedrock outcrops, and the steep offshore gradient.” They go on to note “The shoreline at the entrance of (Indian) Cove is rock and is devoid of sediment. The only source for the littoral zone is material transported into the Cove on the sea-floor as bed-load or in suspension during periods of storm waves.” Although the beach is prograding...the rate of accumulation is slow because of the low volume of sediment input. This is consistent with Project team subsea video observations (Appendix J) and sediment samples taken for granulometric analysis. The marine substrate at Fogerty Head is dominated by coarse materials including cobble, rock, and large boulders; granulometric analysis reported the samples were approximately 75-80% gravel (Section 6.6.2).

In summary, although currents may be significant off Black Point, observations and limited literature reports together suggest that the transport of sediments along shore is minimal in this area, largely due to the paucity of eroding sediments and the generally coarse grain size.

Project interactions with the VC are summarized in Table 7.11-2.

**Table 7.11-2:
Potential Project Interactions with Marine Species and Habitat**

Project Works and Activities	Interaction with VC (Yes / No)	Rationale
Site Preparation/Construction		
Construction of processing plant and associated infrastructure (offices, roads, electrical transmission lines and substation, etc.)	Yes	If uncontrolled, erosion may lead to sediment transport to the marine environment, negatively affecting water quality and near shore habitat.
Construction of the marine terminal	Yes	Marine terminal infrastructure will occupy habitat within the marine environment, killing or displacing the flora and fauna present. Marine construction activities may create or re-suspend bottom sediments, smothering nearby habitats
Operations Phase Works and Activities		
Operations and maintenance of terrestrial infrastructure	Yes	Discharge of sediment-laden surface water to the marine environment may negatively affect water quality; sediment may cover marine flora and harm benthic habitat and affect the quality of fish habitat function.
Pit development (including top soil and overburden stockpiling, explosives use, on-site materials transport)	Yes	Excessive use of explosives near water may cause serious harm to fish.
Ship loading	Yes	Aggregate spills during ship loading may cover marine flora, benthic habitat and affect the quality of fish and habitat function.
Aggregate transport by vessel	Yes	Ship noise and movement may affect the behaviour of marine species negatively affecting their survival; illegal bilge water discharge may introduce invasive species. Propeller wash can affect marine flora and fauna negatively by re-suspending sediments and causing siltation.

Project Works and Activities	Interaction with VC	Rationale
(Yes / No)		
Closure and Rehabilitation Phase Works and Activities		
Partial removal of the marine terminal infrastructure to ensure safety and security	Yes	Limited interactions with marine biota are anticipated during marine terminal decommissioning

Potential effects associated with the Project are:

1. Reduced habitat quality and habitat function due to altered water and sediment quality from sediments introduced to the marine environment during construction and operation. The potential effect of runoff from the terrestrial environment and mitigation measures designed to limit its occurrence are described in Sections 7.4 and 7.6.
2. Reduced habitat for fish that are part of or support commercial, recreational or Aboriginal fisheries resulting from construction of marine terminal.
3. Fish mortality due to the use of explosives within the pit; behavioural changes to fish, crustaceans and other marine species due to noise and vibrations associated with explosives use.
4. Mortality and/or the loss of benthic habitat due to aggregate spills when the ships are loaded.
5. Increased disturbance to marine flora and fauna and reduced habitat quality and function for marine species due to noise and vessel movement from increased ship traffic.
6. Invasive species that may be introduced through the illegal discharge of ballast water.

Effects of Construction

Construction of the marine terminal will remove sea bed habitat even as new habitat is created by the terminal rubble mound foundations. The total seafloor habitat lost will be approximately 11,100 m². The area includes the footprint and impact from rubble fill, caissons, and mooring dolphins. While this habitat is important to the marine biota (flora and fauna) it supports, it is not particularly rare within Chedabucto Bay and does not support any unique characteristics. Table 7.11-3 compares the surface area of the Project footprint within the study boundaries to the size of each of the study areas.

**Table 7.11-3:
Percentage Occupied by the Terminal Within Each Boundary**

Measure	Project Area	Affected Area	Study Area
Area of marine habitat (ha)	1.11	3.87	61,200
Area of marine habitat affected (ha)	1.11	1.11	1.11
% area of marine habitat removed	100	28	0.002

The Study Area includes 61,200 ha of marine habitat. The habitat lost as a result of the terminal will be approximately 1.1 ha. The loss of marine habitat represents less than 0.002% of the total Study Area. The removal of this habitat for the project is not anticipated to limit the amount of suitable available habitat for American lobster or prey species.

Fisheries and Oceans Canada policy requires that Proponents replace or recreate fisheries productivity lost as a result of their projects. Following discussions with local fishermen under the auspices of the GCIFA, it appears likely that rocky substrate suitable for lobster habitat can be created immediately east or west of the Black Point Project site. In these areas, bathymetry restricts suitable lobster habitat to a narrow band in the nearshore. Local fishermen suggest that opportunities exist to widen this band in the immediate Project vicinity.

As noted above, construction of the terminal will disturb the substrate and re-suspend sediments into the water column. Although this may affect marine plants and cause reduced habitat quality leading to mortality of less mobile invertebrates, fish will likely re-locate to adjacent areas to avoid the disturbance. Within the Project Area, the marine substrate is dominated by coarse materials including cobble, rock, and large boulders with smaller areas of fine substrates (sand and silt). The density of marine flora reduces at depths greater than 25 m within and greater than 100 m from shore. The coarse grained nature of the substrate suggests that sediment resuspension during construction will be minimal and is so is not likely to produce a significant effect.

Vibrations associated with pile driving to install the slewing area foundations will result in a zone potentially lethal to fish extending 10 m from the piles (**Appendix D**). Pile driving is expected to occur over several months but will temporary in duration. Additional noise in the marine environment will be created by the placement of rocks making up the rubble mound, installation of the mooring dolphins (pile driving not required) and associated vessel traffic.

Effects of Operation

The detonation of explosives has the potential to cause injury or death to marine fish and mammals in the immediate nearshore area. Concerns regarding the use of explosives have also been raised by some local fishermen; specifically whether the noise and vibrations will affect lobster and mackerel behaviour. Blasting produces compressive shock waves in water followed by a rapid decay to below ambient hydrostatic pressure (Wright and Hopky 1998). Overpressure can damage fish swimbladders, rupture or haemorrhage internal organs, and kill or damage fish eggs and larvae, including crab and lobster eggs and larvae.

To avoid these effects, blasting charge size must be reduced if the location of blast is near the water's edge. For large blasts – on the order of 100 kg per hole – DFO guidelines stipulate a setback of about 150 m is required (Wright and Hopky 1998).

The Standard Shot Design prepared by the Proponent's blasting specialists demonstrates how different blasting configurations will be used closer and farther from water's edge (Table 3.3 in Section 3 - Project Description). These configurations will be used to ensure that maximum acceptable particle velocities for protection of fish will not be exceeded⁸. This is illustrated on **Figure 7.11-1**, which demonstrates that blasting needed to level the lower coastal platform ("cut and fill" on Figure 3.0-26) as well as blasting at the quarry face can be undertaken without exceeding the DFO guidelines.

⁸ Table 2 in Wright and Hopky 1998: *Setback distance (m) from centre of detonation of a confined explosive to spawning habitat to achieve 13mm•sec-1 guideline criteria for all types of substrate.*

Ship loading may result in aggregate spills to the marine environment. Transport of aggregate via seagoing vessels will impact upon the marine environment through noise associated with vessel passage and potentially through accidental spills or other incidents at sea.

During operation, noise produced by ships may adversely affect the behaviour of marine species near the ship loading area and in the travel lanes from the marine terminal to the main shipping lanes. Fish or marine mammals may avoid the area, change migratory routes, and alter feeding habits (Lawson *et al.* 2000). Propeller wash may re-suspend sediment affecting marine plants and relatively immobile marine fauna in relatively shallow areas, although as noted, substrates in the vicinity of the marine terminal are relatively coarse and not likely susceptible to resuspension.

Accidental spills or the release of bilge, ballast or wastewater from ships can affect water quality and negatively affect species in the area. The release of ballast water can also facilitate the introduction of invasive species and potentially alter the aquatic food web structure.

Effects of Decommissioning

The effects are expected to be similar to the construction phase.

7.11.5 Mitigation and Monitoring

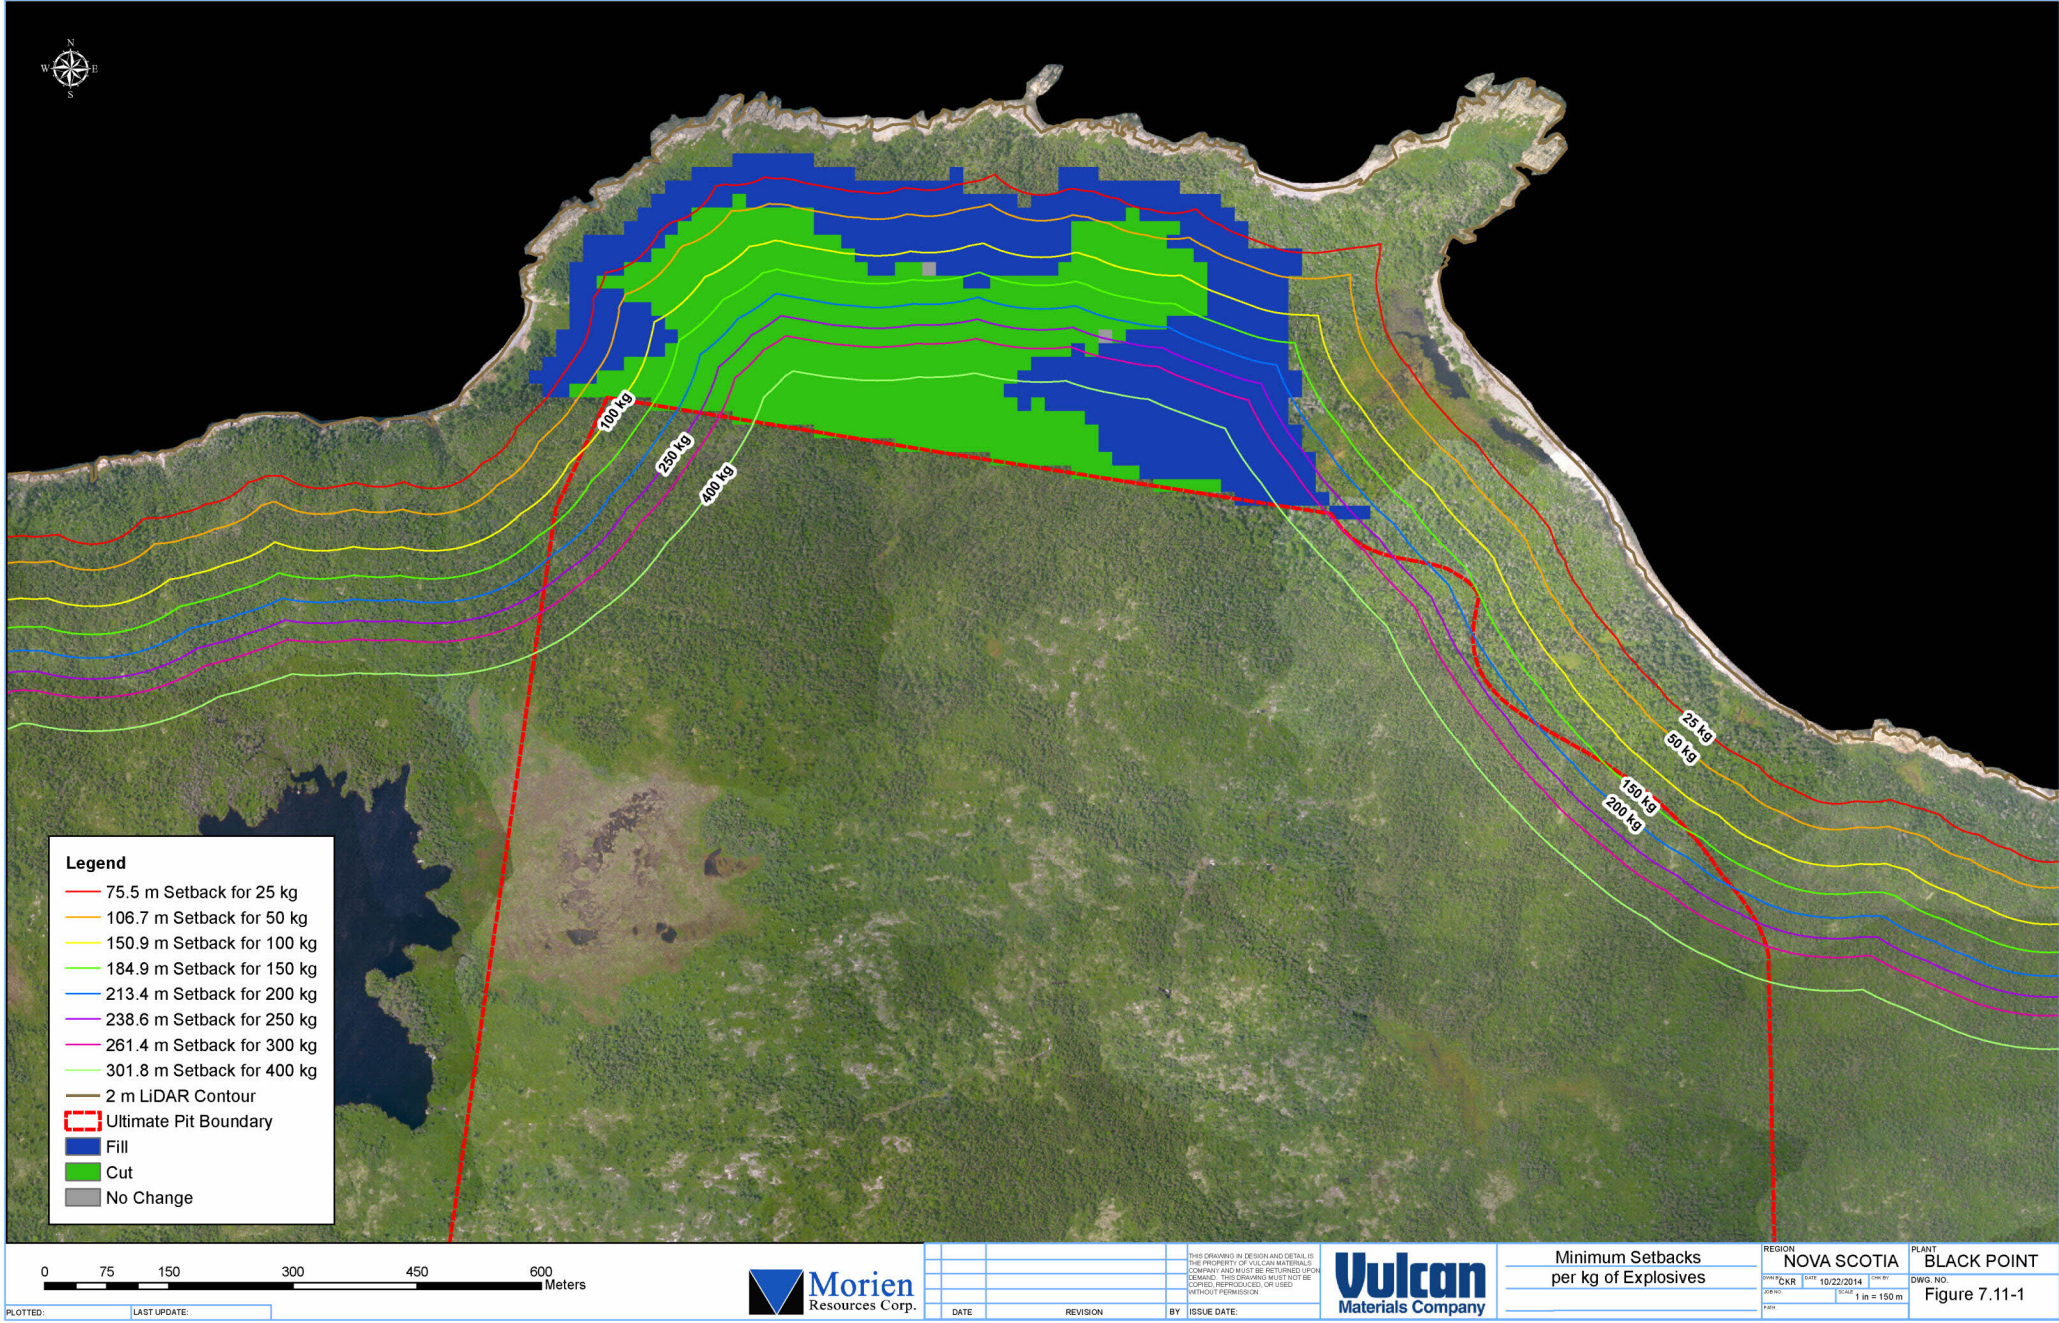

The following additional technically and economically feasible mitigation measures are identified to reduce the severity of adverse effects on Marine Species and Habitat.

Construction

An Environmental Management Plan will describe the following preventative and mitigation measures:

- Application of appropriate timing windows for all in-water work.
- Implementation of terrestrial erosion and sediment control measures.
- Use of surface water monitoring to ensure that quality meets all relevant regulatory standards prior to discharge to receiving environment.
- Installing overburden stockpiles, fuel and chemical storage facilities a minimum of 30 m from Chedabucto Bay.
- Implementation of an Emergency Response and Spill Contingency Plan for Accidents and Malfunctions.

Prior to commencing full blasting operations, field observations will be made to characterize the effects of vibrations on fish habitat. Observations will include measurements of peak particle velocity of substrates and over pressure in fish bearing waters. If peak particle velocities and overpressures meet DFO threshold values, then the Project will proceed with normal blasting operations as assumed for the base case in the vibration assessment. If effects from vibrations exceed the DFO thresholds, then a site specific standard to protect fish and an appropriately scaled fish and fish habitat offset plan will be implemented. This site specific standard may include modified blasting protocols (based on field testing and as currently described) and/or timing of blasts near the marine environment to avoid sensitive periods.

Operation

- Ensure that discharges of water from the operation comply with surface water quality standards
- Locate overburden stockpiles, fuel or chemical storage facilities, and construction equipment a minimum of 30 m from Chedabucto Bay.
- Preparing an Emergency Response and Spill Contingency Plan for Malfunctions and Accidents.
- Control ballast water release via the *Ballast Water Control and Management Regulations* and the requirements as per the International Convention for the control and Management of Ship's Ballast Water and Sediments.

7.11.6 Offset Strategies

Due to the nature of the project, unavoidable serious harm to marine fish and fish habitat will result from the construction of the marine terminal. To counter-balance unavoidable serious harm to fish and loss of fisheries productivity for species that are part of or support a commercial, recreational or Aboriginal fishery, the Proponent will prepare an Offset Plan pursuant to the Fisheries Act Section 35(2)(b). The Offset Plan will be prepared in consultation with Fisheries and Oceans Canada, Environment Canada, local commercial fisherman, and Mi'kmaq groups. Consideration will be given to DFO's four guiding principles, and the fisheries management values and objectives of local commercial fisherman and Mi'kmaq groups.

Offsets will be required for the destruction of approximately 1 ha of marine habitat. The habitat that will be displaced as a result of the marine terminal currently supports invertebrates' species including commercially harvested American Lobster. At present (following discussions with local fishermen), consideration is being given to the following offset measures:

- Artificial reefs
- Eel grass plantings
- Release juvenile lobster
- Improve juvenile lobster habitat

The Project team will evaluate potential offset opportunities that are consistent with local management plans, in proximity to lobster capture locations and have suitable depth, substrate, and vegetation near the Project site.

Artificial reefs can serve as habitat for lobsters and other invertebrates in the study area such as crabs and mussels. Reefs can be designed to incorporate the preferred substrate types such as rock over top of softer substrates. AMEC (2008) indicated that the placement of piles of 15 to 20 cm rock in patches 3 m in diameter and 0.5 m in height would attract adult lobsters. Similarly the placements of rock from 2 to 20 cm plus boulders of 45 to 100 cm would provide habitat within interstitial space for crabs and lobster of different life stages.

Monitoring of the effectiveness of the marine Fisheries Offset Program would be undertaken for at least three years until it can be demonstrated that the program objectives have been met.

7.11.7 Methodology for Determination of Significance

Potential effects of the project on the marine environment include changes in habitat suitability associated with physical habitat alteration, potential exposure to substances entering the water resulting from project activities and changes such as dissolved oxygen, water flow and water temperature regimes. Effects are considered during construction, operation and decommissioning phases of the project. Effects are summarized in a regional context in Table 7.11-4.

7.11.8 Residual Effects and Significance

Residual effects are evaluated after application of mitigation measures. These effects are assessed in the context of:

- Magnitude
- Geographic extent
- Duration
- Frequency
- Reversibility
- Ecological Context

Mitigation by design has been achieved through the evaluation of alternatives as it relates to the layout, construction, and operation of the various project components. Of particular importance was avoiding overprinting of any highly sensitive ecological components.

Provided that the current design plan is used, mitigation measures are followed, and appropriate offset strategies are developed and effective, no significant adverse residual environmental effects on the marine environment are likely to result.

**Table 7.11-4:
Residual Effects on Marine Species and Habitat**

Project Environment Interaction	Potential Residual Environmental Effects A=Adverse P= Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Effect
Noise and vibration effects to marine biota from blasting and pile driving	A	See Mitigation Section	1	2	1/6	R	1	Temporary disturbance	Not Signif.
Permanent loss of habitat (flora, substrates) resulting from the construction and operation of the marine terminal	A	See Mitigation Section	1	1	3/1	R	1	None anticipated following implementation of Offset	Not Signif.
Effects on marine water quality due to construction of the marine terminal and/or spills or discharges from the terrestrial environment	A	See Mitigation Section	1	1	1/1	R	1	None anticipated	Not Signif.
Re-suspension of sediments from propeller wash affecting marine flora and fauna and their habitat in relatively shallow water	A	See Mitigation Section	1	1	1/5	R	1	None anticipated	Not Signif.

Disturbance of seabirds and waterfowl marine terminal activity and vessel movement between the terminal and the main shipping lanes approximately 7 km from the terminal	A	See Mitigation Section	1	2	1/4	R	2	None anticipated	Not Signif.
Illegal discharge of ballast water	A	See Mitigation Section	1	2	1/1	I	1	None anticipated	Not Signif.

Legend									
<u>Magnitude:</u>			<u>Geographic Extent:</u>			<u>Frequency:</u>		<u>Ecological / Socio-Economic Context:</u>	
U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.			1 = < 1 km ²			1 = < 11 events/year		1 = Relatively pristine area or area not adversely affected by human activity.	
0 = Nil - No environmental effect.			2 = 1 – 10 km ²			2 = 11 – 50 events/year		2 = Evidence of adverse environmental effects.	
1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)			3 = 11 – 100 km ²			3 = 51 – 100 events/year			
2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)			4 = 101 – 1,000 km ²			4 = 101 – 200 events/year			
3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)			5 = 1,001 – 10,000 km ²			5 = > 200 events/year		N/A = Not applicable

			1 = < 1 month			<u>Reversibility:</u>		P = Positive	
			2 = 1 – 12 months			R = Reversible			
			3 = 13 – 36 months			I = Irreversible			
			4 = 37 – 72 months						
			5 = > 72 months						

7.12 SAR and SOCC

This section discusses the potential impacts of the Project on SAR and SOCC on the Project site. Existing flora and fauna SAR and SOCC are described in Section 6.7.

7.12.1 Boundaries

The Project Area and Affected Area spatial ecological boundaries for terrestrial wildlife include all environments within the footprint of the Project (including the access road), as well as all environments within 500 m of the Project site and the shipping routes offshore in habitats utilized by marine species (including mammals, fish, and reptiles). This buffer is considered to be the maximum extent to which noticeable effects on SAR can be reasonably expected as a result of Project components and activities.

The temporal ecological boundaries encompass every year of all phases of the Project, including construction, operation and decommission. Within each year, interactions between terrestrial fauna and Project components or activities can occur year round.

With respect to the administrative and legislative boundaries, the *Nova Scotia Endangered Species Act* (NSESA) and the federal *Species at Risk Act* (SARA) offer legal protection to species that have been proclaimed as endangered, threatened or vulnerable under these *Acts*.

7.12.2 Threshold for Determination of Significance

A significant adverse effect of Project components or activities on a SAR or SOCC is defined as an effect that causes a decline in abundance and/ or a change in distribution beyond which natural recruitment (reproduction and immigration from unaffected areas) would not return the population to its pre-project level within several generations. Mortality of a single individual of a Species at Risk could also be considered a significant adverse environmental effect.

Effects on critical habitat of a migratory bird SAR which cause breeding failure or abandonment of nesting may also be considered significant, even if the effects are temporary. This would include abandonment or nesting failure of a migratory bird SAR due to an accidental event or the response to an accidental event associated with the Project.

A significant adverse effect on sensitive/ critical habitat is defined as an adverse effect that causes a net loss of habitat function.

An adverse effect that does not cause such declines or changes is not considered to be significant.

A positive effect occurs when Project activities help increase abundance or diversity of species or enhances habitat.

7.12.3 Effects on Terrestrial Flora SAR/SOCC

Terrestrial SOCC on the project site include both vascular plants and lichens. Potential effects to each of these taxa are discussed separately in the following subsections.

Vascular Plants

Two vascular plant SOCC are known to occur in the Project footprint. These are Northern Commandra (*Geocaulon lividum*) (GSWSC 3 (Sensitive)) and Southern Twayblade (*Listera australis*, GSWSC 3 (Sensitive)). Northern Commandra occurs to the south of the main Project boundary, but lies along the proposed access road. Southern Twayblade was found in two areas, both within the planned Project footprint. Potential effects on Northern Commandra and Southern Twayblade are expected to be similar to effects on vascular plant species as a whole, which are discussed in detail in Section 7.7. Potential effects of the Project phases on flora SAR are summarized in Table 7.12-1.

**Table 7.12-1:
Summary of Potential Impacts of the Black Point Quarry Project on Species at Risk (SAR) and Species of Conservation Concern (SOCC) by Project Phase**

Priority Species in Project Area Potentially Affected by Project	Critical Habitat Present in Project Footprint	Potential Effects																	Specific Comments
		Direct Mortality	Loss of Habitat	Habitat Alteration	Disturbance/Displacement	Increased Noise	Increased Dust	Blasting Effects	Increased Human Presence	Sedimentation / Erosion	Decreased Air Quality	Decreased water Quality/Quantity	Alterations to Hydrology	Establishment of invasive Species	Increased Site Lighting	Exposure to Contaminant	Accidents and Malfunctions	Creation of Suitable Habitat

Note: No terrestrial Amphibian or Reptile (collectively herpetile) SAR are known or suspected to occur on the site or nearby and therefore are not discussed in this table.																			

Lichens

Four lichen SOCC are known to occur on the Project site. These are Black-footed Reindeer Lichen (*Cladonia stygia*), Naked Kidney Lichen (*Nephroma bellum*), Coastal Bushy Beard Lichen (*Usnea flammea*), and Angel Hair Ramalina (*Ramalina thrausta*). All of these are listed as 3 (Sensitive) on the GSWSC list for NS.

Black-footed Reindeer Lichen occurs in several locations on the Project site, with 19 occurrences detected. Naked Kidney Lichen and Coastal Bushy Beard Lichen both occur in two locations, with one report of each from the northern and southern portions of the property, respectively. Angel Hair Ramalina is known to occur at one location near the centre of the site. The endangered Boreal Felt Lichen is not known to occur in the general area and was not found on site. Polygons of potential Boreal Felt Lichen habitat, as mapped by NSE (2009), are considered to be too far away from the Project site to be affected by Project activities, such as dust emissions.

It is likely that most of these four species occurring on the Project site will experience some direct mortality from Project activities. Overall, potential effects on lichen SAR and SOCC are expected to be similar to those outlined for lichen species as a whole, in Section 7.1. Potential effects of the Project phases on lichen SAR/SOCC are summarized in Table 7.12-1.

7.12.4 Effects on Terrestrial Fauna SAR/SOCC

For most terrestrial fauna SAR/SOCC (including the one mammal, fourteen bird, and one odonate), potential effects are predicted to be similar to those for terrestrial fauna as a whole (Section 7.7). Potential effects of the Project phases on all terrestrial fauna SAR/SOCC are summarized in Table 7.12-1.

The following subsections focus on terrestrial fauna SAR/ species which are known to occur on the Project site.

7.12.4.1 Mammals

Moose

The mainland Nova Scotia population of Eastern moose, which is listed as Endangered under the *NSESA*, could potentially be affected by the proposed Project in a variety of ways. Potential impacts to Mainland Moose are summarized in Table 7.12-1. They include:

- Loss of habitat (foraging, wintering, calving);
- Habitat fragmentation;
- Disruption of migratory routes;
- Mortality due to vehicle collisions;
- Increased poaching levels in area due to increased traffic;
- Noise disturbance; and
- Exposure to runoff from hazardous materials/contaminated soils.

Habitat loss will occur on the site due to site development and clearing activities for the main Project site and the access road. Important habitats for Moose tend to be wintering and calving areas. Preferred wintering habitat for Moose in Nova Scotia typically consists of mature conifer or mixed conifer stands, where snow accumulation is decreased and browse is available, reducing winter energy demands (Parker 2003). Approximately 213 ha of coniferous forest and wetland occurring on the Project site will be removed during site development. This parcel of habitat is not part of a core Moose habitat polygon which encompasses much of Guysborough and Antigonish counties (Parker 2003), and so should not be considered significant. The development of the Project is not expected to significantly affect Moose wintering based on current knowledge. However Moose winter track and spring pellet surveys are planned in the area during the winter of 2015 and will provide site specific data related to site utilization of Moose during the winter.

Moose tend to utilize areas associated with aquatic/wetland areas for calving, but will also use islands in beaver ponds and wetland areas with standing water (Parker 2003). There is little of this habitat on site, and standing water areas occur mostly along the shore, where the exposure likely limits the utility of these locations as calving areas. The low density of Moose in the area, combined with the abundance of similar and much larger wetlands throughout the region results in the proposed Project having very little potential to adversely affect calving.

Land clearing on the Project site (213 ha) and the creation of the access road (800 m in length) will contribute to habitat fragmentation in the region. Land clearing for silviculture has also occurred to the east in the vicinity of Fox Island Main. The region is crisscrossed by many small logging and ATV roads and the effects of the Project are predicted to be insignificant within the region.

The increased visitation of and/or residency in the region during the construction and operations phases could also lead to impacts on Moose due to increased poaching activity. Mainland Moose are endangered and hunting them is not permitted; however, poaching continues to be a concern. The presence of the Project on the site, combined with strict reporting policies for any suspected Moose hunting activities in the area, will help to mitigate this potential effect.

It is possible that Moose could be affected by an accident within the Project site resulting in an off-site forest fire, although this is not considered likely. For a discussion of accidental events, possible consequences and preventative measures refer to Section 7.19.

Increased road traffic in the area due to the Project could potentially lead to increased risk of collisions with Moose, potentially leading to mortality. Vehicle use on-site could also result in accidental mortality of Moose. As very few Moose are present in the area, it is unlikely that encounters will occur; however, it is important to recognize the importance of each individual Moose within the small Guysborough population.

The development of the Project site could potentially hinder some small-scale seasonal movements of Moose. Fencing around the site will prevent Moose from accessing the site, forcing them to travel around the site boundaries if they desire. However, the low density of Moose in the area, combined with the relatively small distance such a detour would require, in relation to a Moose's home typical territory, results in this effect being insignificant.

Noise associated with construction and/or decommissioning and reclamation activities may disrupt Moose within several hundred metres of the active area; however, similar habitat is available throughout the adjacent area and impacts at the population level are not expected.

Effects of the decommissioning phase on Moose are considered to be similar to the construction phase, with the addition of the possible recreation of suitable habitats. Decommissioning activities and site reclamation could possibly have slight temporary negative effects on Moose; however, the effect of the resulting reclamation on Moose is expected to be positive, with rehabilitation of suitable terrestrial habitats and possibly wetlands.

Mitigation measures for these potential effects are outlined in Section 7.9. Potential effects and mitigation for malfunctions and accidents, such as spills, are discussed in Section 7.19.

7.12.4.2 *Birds*

To date, a total of fourteen bird SOCC have been reported from the Project site. Of these, a single species, the Rusty Blackbird, is actually a SAR, as it was listed as Endangered under the *NSESA* in 2013. Mitigation for potential impacts to this species is outlined in the following subsection.

Rusty Blackbird

Rusty Blackbird, which is listed as Endangered under the *NSESA*, could potentially be affected by the proposed Project in a variety of ways. Potential impacts to Rusty Blackbird are summarized in Table 7.12-1. They include:

- Loss of habitat (foraging, nesting);
- Habitat fragmentation;
- Disturbance from construction noise (including blasting); and
- Exposure to runoff from hazardous materials/contaminated soils.

Habitat loss will occur as a result of the Project due to site development and clearing activities for the main Project site and access road. Rusty Blackbirds tend to prefer cool habitats in forest openings, including spruce bogs, swamps, and damp alder swales. They construct their nests from 0.5 to 6 metres above the ground or water. They do not overwinter in Nova Scotia.

Approximately 213 hectares of coniferous forest, shrub barrens, coastal barrens, mixed forest, and wetland occur on the site and will be removed by the Project over time. Not all of this is suitable habitat for Rusty Blackbirds. This will not occur at once, but over several decades. Progressive reclamation of the pit will ensure that new terrestrial and possibly wetland habitat is created prior to the closure of the quarry.

Land clearing on the Project site (213 ha) and the creation of the access road (800 m in length) will contribute to habitat fragmentation in the region. The region is crisscrossed by many small logging and ATV roads and the effects of the Project are predicted to be insignificant within the region.

The increased visitation of and/or residency in the region during the construction and operations phases could also lead to impacts on Rusty Blackbird breeding due to increased disturbance. Flushing of birds from their nests can have significant impacts on both adult birds and nestlings

due to stress and increased predation (see Section 7.9 for a more detailed discussion). Noise associated with construction and/or decommissioning and reclamation activities may disrupt Rusty Blackbirds within a few hundred metres of the active area; however, similar habitat is available throughout the adjacent area and impacts at the population level are not expected.

It is possible that Rusty Blackbirds could be affected by an accident within the Project site resulting in an off-site forest fire, although this is not considered likely. For a discussion of accidental events, possible consequences and preventative measures refer to Section 7.19.

Effects of the decommissioning phase on Rusty Blackbird are considered to be similar to the construction phase, with the addition of the possible recreation of suitable habitats as revegetation progresses. Decommissioning activities and site reclamation could possibly have slight temporary negative effects on Rusty Blackbird; however, the effect of the resulting reclamation on RBB is expected to be positive, with rehabilitation of suitable terrestrial habitats and possibly wetlands.

Mitigation measures for these potential effects are outlined in Sections 7.9 and Section 7.19.

7.12.4.3 *Herpetiles*

No terrestrial herpetile SAR or SOCC are known or suspected to occur on the Black Point site. Therefore, potential impacts to terrestrial herpetile SAR and SOCC are not discussed in this section.

7.12.4.4 *Invertebrates*

A single invertebrate SOCC species, a dragonfly known as the Spot-winged Glider was detected on the site in 2010. Mitigation for potential impacts to invertebrate SAR and SOCC is covered by the mitigation for terrestrial fauna, freshwater fauna, and wetlands, which are discussed in detail in Section 7.8, Section 7.9, and Section 7.10.

7.12.5 *Effects on Freshwater Flora and Fauna SAR/SOCC*

No freshwater flora or fauna SAR or SOCC are known or suspected to occur on the Black Point site. Therefore, potential impacts to freshwater SAR and SOCC are not discussed in this section.

7.12.6 *Effects on Marine Fauna SAR/SOCC*

Several marine fish, mammal, and reptile SAR and/or SOCC have the potential to occur within the marine footprint and immediate vicinity of the Black Point Project site. Potential effects on marine fauna SAR and SOCC are predicted to be similar to those for marine fauna as a whole, which are discussed in detail in Section 7.11. The potential effects of each of the Project phases on marine fish, mammal, and reptile SAR and SOCC are summarized in Table 7.12-1.

7.12.7 *Mitigation & Monitoring*

Mitigation for potential effects on SAR and SOCC are similar to recommendations for terrestrial or marine fauna as a whole (Section 7.11).

7.12.7.1 *Terrestrial SAR/ SOCC*

Vascular Plant SAR/SOCC

Standard mitigation measures such as minimization of Project footprint, dust control, emissions control, and monitoring of air quality targets as detailed in Sections 7.7 and 7.1 will be sufficient to protect vascular plant SOCC. No vascular plant SAR are known to occur on the Project site.

As part of the EMP compliance monitoring, a program of identification and removal of noxious or exotic invasive weeds can be established. This program would include consideration for seasonality and risk associated with species known to occur in NS.

Lichen SAR

Standard mitigation measures such as dust control, emissions control, monitoring of air quality targets and minimization of Project footprint as detailed in Sections 7.7 and 7.1 will protect lichen SOCC.

No lichen SAR is known to occur on the Project site.

7.12.7.2 *Terrestrial Fauna SAR/SOCC*

Mitigation for potential effects to terrestrial habitats, wetlands, and terrestrial fauna is discussed in detail in Section 7.7, Section 7.8, and 7.9. These mitigation measures should be sufficient to minimize potential impacts to bird, mammal, reptile, odonate and lepidopteran SAR/SOCC potentially occurring in the Project area. Specific mitigation for SAR species known to occur on Project site are discussed for the various terrestrial fauna groups in the following subsections.

Mammals

Standard mitigation measures for wildlife, as detailed in Sections 7.9 will protect mammal SAR and SOCC. A single mammal SAR is known to occur on the Project site, and specific mitigation for this species is outlined in the following subsection.

Moose

Mitigation for potential effects to terrestrial habitats, wetlands and terrestrial fauna, is discussed in detail in Section 7.7, Section 7.8, and Section 7.9. Mitigation measures for mammals should be adequate to mitigate potential effects on mainland Moose in the area.

Standard handling and storage procedures for hazardous material, as well as procedures for handling and disposal of contaminated soils (outlined in Section 7.18), will adequately mitigate the potential for exposure of Moose to any hazardous materials or contaminated soils.

Strict reporting policies for any suspected hunting activities in the area will help to minimize any potential Moose poaching in the Project area.

Imposing a 50 km/hr speed limit will reduce the potential for vehicle-moose collisions on-site year-round. It will also decrease encounters between humans and Moose.

As the Project will be causing some loss of Mainland Moose habitat, the Proponent will consider contributing to efforts on conservation of mainland Moose, via support for the Mainland Moose Recovery Team and/or the Assembly of Nova Scotia Chiefs program for Moose recovery being administered by the Unama'ki Institute of Natural Resources. Details of the Proponent's participation in, or contribution to, these programs can be negotiated and finalized upon environmental assessment approval and in consultation with DNR. A Moose Management Plan may also be implemented to provide information and assist in the recovery of Moose in the Project area.

Birds

Standard mitigation measures for terrestrial habitats, wetlands, and terrestrial fauna, as discussed in detail in Section 7.7, Section 7.8, and Section 7.9 will protect bird SAR and SOCC. A single bird SAR is known to occur on the Project site, and a second has been identified as having potential to occur and has been included as a precaution; specific mitigation for these species is outlined in the following subsection.

Rusty Blackbird

Mitigation for potential effects to terrestrial habitats, wetlands, and terrestrial fauna, is discussed in detail in Section 7.7, Section 7.8, and Section 7.9. Mitigation measures for birds should be adequate to mitigate potential effects on Rusty Blackbird in the area.

Standard handling and storage procedures for hazardous material, as well as procedures for handling and disposal of contaminated soils (outlined in Section 7.18), will adequately mitigate the potential for exposure of Rusty Blackbird to any hazardous materials or contaminated soils.

Common Nighthawk

Common Nighthawk (*Chordeiles minor*) is a migratory SAR which has the potential to occur on the Property, and which EC-CWS has requested is addressed in this assessment. Nighthawks are often not detected during standard breeding bird point count surveys due to their nocturnal nature. Evening surveys to determine the presence of this crepuscular/nocturnal species were not conducted on the Project site. A precautionary measure, the Proponent is preparing this EIS report under the assumption that this species may be seasonally present.

Mitigation for potential effects to terrestrial habitats, wetlands, and terrestrial fauna is discussed in detail in Sections 7.7 - 7.9. Standard mitigation measures for birds should be adequate to mitigate potential effects on Common Nighthawk in the area, with the additional measure of ensuring that any exposed soils and soil stockpiles are adequately covered or vegetated to deter Common Nighthawks from nesting on them.

Should Common Nighthawks initiate breeding activities on stockpiles or exposed areas on site despite efforts to deter them, the Proponent will establish a 20 m buffer around the location once identified, and contact CWS for further advice. Periodic monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area.

Herpetiles

No mitigation for herpetile SAR and/or SOCC is necessary, as none are known or suspected to occur on the Project site.

Invertebrates

Mitigation for potential effects to terrestrial habitats, wetlands, and terrestrial fauna, is discussed in detail in Section 7.7, Section 7.8, and Section 7.9. These measures should be sufficient to any mitigate potential effects on Spot-winged Glider, the single SOCC reported from the Project site.

7.12.7.3 Freshwater SAR/SOCC

As no freshwater SAR or SOCC are known or suspected to occur on the Black Point Project site, mitigation for such is not necessary. Mitigation for potential effects to freshwater fauna and habitats is discussed in detail in Section 7.10.

7.12.7.4 Marine SAR/SOCC

Mitigation of potential effects on marine fauna (fish, mammals, and reptiles) is discussed in detail in Section 7.11. This is applicable to marine fish, mammal, and reptile SAR and SOCC which are considered to have potential to occur within the Project spatial boundaries. While no marine fauna SAR or SOCC have been reported from the marine portion of the Project site, their potential presence cannot be discounted, as marine surveys were beyond the scope of this report. A Marine Habitat Offset Plan is also being developed to mitigate the loss of a small amount of marine habitat within the Project footprint.

7.12.8 Summary and Residual Effects

Table 7.12-2 provides the results of the effects assessment for all flora and fauna SAR/SOCC for the construction and operation phases of the Project. Effects associated with the decommissioning phase are expected to involve similar issues as those discussed for the construction phase.

Table 7.12-2 also provides a summary of recommended mitigation measures and residual environmental effects after successful implementation of the mitigation measures described above. With respect to both the Flora and Fauna SAR/SOCC, Project activities are not likely to result in significant adverse residual effects on SAR or SOCC with proper implementation of recommended mitigation measures.

**Table 7.12-2:
Residual Environmental Effects for Species at Risk (SAR)**

Project-Environment Interaction	Potential Positive (P) or Adverse (A) Effect	Mitigation	Significance Criteria for Residual Environmental Effects						
			Magnitude	Geographic Extent	Duration/Frequency	Reversibility (R=reversible NR=Non reversible)	Ecological/Social-cultural and Economic Context	Residual Effect	Significance
Construction/Decommissioning and Operations									
Terrestrial Flora SAR/SOCC (Vascular Plants, Lichens)									
Direct and indirect plant mortality due to displacement or loss of biota. 7.13 LOCAL ECONOMY, LAND AND RESOURCE USE

7.13.1 Overview

Positive economic effects of the Project will benefit local residents, local businesses in the service sector and government at the municipal and provincial levels. Direct financial benefits to government include corporate taxes and taxes on goods and services. Indirect benefits include increased personal income taxes from local residents that are either involved as employees or contractors with the Project. Improvements in the regional economy can positively affect the population size and demographics as workers move to the area, purchase real estate, goods and services, and raise families. Real estate values can also be positively affected by a vibrant regional economy.

The Project will require a temporary labour force during construction and a smaller but significant labour force over the long term operation of the Project. In addition to direct hires, the Project will generate employment and economic activity through contracting for goods and services.

A major development such as the proposed Project can affect existing as well as planned land uses. Current on-site land uses (trapping, local tourism) will be replaced by quarrying and associated activities. Existing and planned land uses on adjacent properties or within the Affected Area may be impacted through changes to the visual or acoustic environments. In addition, a vessel collision or fuel spill in the marine environment may affect the local economy and alter existing land and resource use patterns.

7.13.2 Boundaries

7.13.2.1 Temporal Boundaries

The temporal boundaries for the assessment of impacts upon Local Economy, Land and Resource Use begin with the construction phase of the Project and continue through the operational phase and decommissioning phases. Construction time is estimated at two to three years and closure and decommissioning is expected to require two years. Quarry operations are expected to continue for at least 50 years.

7.13.2.2 Spatial Boundaries

The spatial boundaries for the assessment of the Local Economy do not include the Project Area (i.e., within the Project property boundaries) since no opportunities for the purchase of goods and services, beyond those purchases associated with the Project, will be available on site. The spatial boundaries extend to the Affected Area, which includes adjacent lands up to and including Gaulman Point, Fox Island Main and the portion of Highway 16 between these areas. Economic impacts within the Study Area include the limits of the MODG but are generally confined to the area between Guysborough and Canso where communities are expected to be most affected by employment and service opportunities.

With respect to Land and Resource Use, spatial boundaries include all three zones: the Project Area, the Affected Area, and to a lesser extent, the Study Area defined as the MODG.

7.13.2.3 Administrative Boundaries

Land use is regulated by the Province and through municipal zoning and land use bylaws. The Municipality of the District of Guysborough Municipal Planning Strategy (MPS 2013) describes the municipality's intentions for future development. The MPS outlines criteria for Council and planning staff to consider when evaluating development proposals and issuing development permits. Together with the Land Use Bylaw and Subdivision Bylaw, the MPS controls future land use and development in the Municipality.

The sea bed Crown lease needed to build the marine terminal is administered by the Province of Nova Scotia, Department of Natural Resources. An application for this lease has been submitted to NSDNR.

7.13.2.4 Technical Boundaries

Although a variety of economic models may be employed to predict the economic effects of a project, the analysis below uses a simpler approach to assessing economic benefit. The assessment is based on comparing the relative scale of predicted Project-related employment levels (both in terms of person-hours and in terms of wages paid) with existing employment opportunities within the MODG, especially the area between Guysborough and Canso. This is a qualitative assessment and does not include a description of the multiplier effects that may be expressed using Input-Output modelling. Nevertheless, the analysis is sufficiently robust to demonstrate whether the Project is likely to produce positive or negative economic effects in the region.

7.13.3 Threshold for Determination of Significance

A significant adverse Project effect on the Local Economy is defined as one that results in a long term decrease in economic activity or employment opportunities within the Study Area. A significant positive effect is one that results in a long term employment gains and/or sustained economic activity within the Study Area.

A significant adverse effect on Land and Resource Use is defined as a pervasive change in land use patterns within the Study Area that adversely affects a community's use of that land and/or is inconsistent with a designated land use established through a municipal planning process. A positive effect is one that enhances the land's cultural or economic value to the community in a manner that is consistent with the regulatory planning process.

7.13.4 Effects on Local Economy, Land and Resource Use

Local Economy

The positive economic impacts are principally related to long term employment opportunities which typically result in amplified demand for goods and services, as well as improved tax revenues for municipal, provincial and federal governments. As existing employers expand or new employment is created, new employees spend their earnings and the local economy expands to meet these increased demands. An expanding economy can create a feedback loop where businesses that must expand to meet rising demand in turn increase their purchases at other local business which must expand in turn.

Fundamentally, regional economic impacts associated with individual projects are dependent on the size and duration of expenditures, and upon the ability of the local economy to accommodate these expenditures. It is important that housing, groceries, gasoline, hardware, recreational opportunities and a host of other goods and services are readily available in the local area, in order to prevent consumers from seeking these goods and services elsewhere.

Project construction and operation will create direct employment of those engaged to construct and operate the quarry (50-60 people), as well as indirect employment through the demand for goods and services including contractors to support the Project. Ultimately, this local economic activity will be reflected in regional and provincial economies. These economic effects are considered as positive Project-related impacts that do not require mitigation or monitoring.

It is difficult to determine the effect the quarry may have, if any, on property values. The Proponent notes that in their experience, property values may increase as quarry workers seek homes near to their work location. Alternatively, property values may decrease due to perceived quarry impacts (e.g., noise) and/or other, non-quarry related reasons (i.e., continued out-migration).

At this time, there is a local labour pool to support this Project. Conversations with local residents suggest that many young skilled and unskilled workers are currently seeking employment outside of Nova Scotia and would be happy to return to well paying jobs in Guysborough Co. There is a total work force of approximately 13,600 in the Strait Region (Statistics Canada 1996). Of these, 1,500 are experienced in primary industries, 1,800 in manufacturing, 1,000 in construction and 900 in transportation. Additional experienced labour is present in Cape Breton and northern mainland Nova Scotia. Given the current labour availability relative to the demand, no negative effects on the labour supply are anticipated.

The Proponent estimates that up to 120 to 150 people will be directly and indirectly employed over the 36 month construction period beginning in 2017. The primary job types required for the construction work include truck drivers, concrete trades, equipment operators, piping trade, industrial welders, and general labourers. The Proponent has expressed a public commitment to source labour from within the Province of Nova Scotia to the extent that these people are available and interested in the work.

Total construction expenditures are estimated at \$80 to \$110 million over 36 months, or \$27 to \$37 million on an annualized basis. This will have an estimated direct and indirect GDP impact to the Province of Nova Scotia of \$39 to \$53 million per year, and \$6.5 to \$8.8 million per year total GDP for the MODG (based on 1999 Nova Scotia input-output multipliers for oil and gas engineering construction). Provincial taxes for the 3-year construction period will be in the range of \$2.0 to \$2.6 million, with federal taxes at \$2.4 to \$3.2 million. The Proponent has engaged in preliminary discussions regarding labour and training requirements with local labour unions and educational institutions. The Proponent intends to continue this dialogue to ensure that the local force is informed with respect to skills needed.

The following estimates of operational economic impacts were calculated using both low and high production scenarios of 2 and 5 million tonnes, respectively. During the operation of the facility, employment is estimated to be between 50 to 60 full time positions, with 95% of these jobs sourced from the MODG and nearby areas. The employment income to these workers will be from \$2.9 to \$3.4 million per year. Annual GDP is expected to range from \$9.7 to \$24 million for the Province, with the MODG collecting 40% of this revenue; \$3.9 to \$9.8 million. Total GDP

contribution over the 50-year period is expected to range from \$485 million to \$1.2 billion for the Province and from \$195 to \$490 million for the MODG. Annual provincial taxes will be in the range of \$0.9 to \$2.2 million, with federal taxes marginally higher at \$1.0 to \$2.6 million.

A vessel collision or other accident resulting in a fuel spill in the marine environment would have negative effects on Land and Resource Use (see below) as well as on Tourism and Recreation (Section 7.14) and Commercial Fisheries (Section 7.15). These effects would have direct and indirect negative economic consequences as described in the sections cited. In contrast, monies disbursed for cleanup and restoration of a marine fuel spill may partially offset these negative consequences through direct employment of vessels, workers, equipment and related services.

Project related economic effects to commercial fishing are described in Section 7.15.

Land and Resource Use

A diverse assortment of land uses are commonly used to accommodate the various municipal planning objectives in a given area. These objectives include different types of residential and commercial development, parks and recreational spaces, and industrial development. In order to foster long term land use planning and integrate these land use changes into the existing municipal fabric over time, municipalities rely on municipal planning strategies (MPS). The MODG MPS outlines the municipality's vision for land use within its jurisdiction over the coming 20 years or so.

The land designated for the Black Point Quarry Project was assembled by the municipality through a land exchange with the province, combined with the expropriation of two privately owned parcels within the current Property boundaries. Within the long term MPS, this land has been zoned Industrial Heavy I-2. Permitted uses for this zoning includes, among other activities, "rock quarry operation or open-pit mines from which rocks or minerals are extracted" (MODG 2013). One of the primary effects of the Project on the Land and Resource Use VC is to change the use of the Property from an undeveloped piece of land used occasionally for trapping and recreational activities (ATV passage and fishing in the nearshore), to a quarry that will be operated on a continuous basis for roughly 50 years, and where these current activities will eventually be limited or no longer practical. Despite these land use changes, the current zoning reflects a long term municipal vision to promote economic development and so is compatible with the goals and objectives of the community.

With respect to accidental events, a vessel fuel spill in the marine environment would likely result in changes to land and resource use in the vicinity of spill over the short and medium term (estimated at 5-15 years). Depending on where the spill occurred and the volume of fuel released, people may refrain from boating in the area and visiting favourite beaches and headlands.

7.13.5 Mitigation and Monitoring

7.13.5.1 Mitigation

For safety reasons, occasional recreational activities that are currently practiced within the Project's terrestrial boundaries (ATV passage and trapping) will be restricted during construction and operation. Recreational users will be notified of restricted access by signage at the entrance

to the construction site. Restriction of the informal recreational use of the Property may be an inconvenience, but is not likely to be significant. Similarly, marine recreational fishing that currently occurs on an occasional basis in the vicinity of the Project may no longer be practiced. Since many other recreational fishing opportunities nearby, this effect is not considered significant.

All of the mitigation measures presented elsewhere in the EIS are applied to reduce actual and perceived project impacts, which in turn may directly or indirectly affect property values.

Vessels will not be refuelled at the marine terminal and fuel used at the quarry will be kept in double hulled reservoirs or will be placed within secondary confinement and protected against collision. This helps to minimize the risk of accidents at the terminal. In the event of a spill on land, site drainage is directed south to the settling ponds rather than north to Chedabucto Bay. This in turn helps to contain any spills and allow them to be cleaned up. Navigational safety mitigation measures and emergency response planning measures are presented in Section 7.18.3.

7.13.5.2 Monitoring

No follow-up monitoring will be implemented with respect to the effects of the Project on Land and Resource Use. Similarly, no follow-up monitoring will be undertaken with respect to the effect of the Project on the Local Economy.

7.13.6 Residual Effects and Significance

There are no significant adverse environmental effects on the Local Economy. In contrast, positive impacts can be anticipated in the form of direct and indirect employment resulting in regional economic development. Land use changes are consistent with the community desire for this property, as expressed in the Municipal Planning Strategy. No significant residual effects are anticipated with respect to the predicted change in Land and Resource Use.

**Table 7.13-1:
Residual Environmental Effects for Local Economy, Land and Resource Use**

Project Environment Interaction	Potential Residual Environmental Effects (A = Adverse; P = Positive)	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance

7.14 TOURISM AND RECREATION

7.14.1 Overview

Residents and tourists alike utilize the local terrestrial and marine landscapes for outdoor activities such as camping, hiking, fishing, boating, off-road motoring, and hunting. These activities are popular and to a certain degree, available, due to the largely undeveloped nature of Guysborough County. Tourism and recreational activities, as well as the infrastructure associated with these activities, such as accommodation, marinas, recreation centres and parks, make up the Tourism and Recreation VC. The presence of a quarry may influence perceptions regarding noise and changes in the visual character of the coastal landscape, resulting in changes to resource use patterns. The Project may result in restrictions to currently accessible beaches and headlands. A fuel spill in the marine environment that attains local beaches and headlands would likely reduce the appeal of the affected area and other parts of the county to tourists and recreational users.

Details of existing tourism and recreational activities are presented in Section 6.8.

7.14.2 Boundaries

7.14.2.1 Temporal Boundaries

The temporal boundaries for the assessment of impacts upon tourism and recreation begin with the construction phase of the Project and continue through the operational phase and decommissioning phases. Construction time is estimated at two to three years and closure and decommissioning is expected to require two years. Quarry and shipping operations are expected to continue for at least 50 years.

7.14.2.2 Spatial Boundaries

The spatial boundaries for the assessment of impact on Tourism and Recreation are within the Project Area (i.e., within the Project property boundaries) and extending to the Affected Area, which includes adjacent lands up to and including Gaulman Point, Fox Island Main and the portion of Highway 16 between these areas. In the event of a marine spill to the environment, the Affected Area would include coastal regions affected by the fuel.

7.14.2.3 Administrative Boundaries

For safety, it is expected that recreational and commercial boating traffic will be excluded from areas immediately surrounding the marine terminal. Navigability of water courses and coastal waters is regulated by federal legislation under the *Navigation Protection Act*.

7.14.2.4 Technical Boundaries

While a certain amount of data regarding tourism in Nova Scotia is available for review, no statistical data was found to describe expenditures on tourism and recreational activities within the MODG.

7.14.3 Threshold for Determination of Significance

A significant adverse effect on Tourism and Recreation is defined as a permanent and widespread change in tourism or recreational activities such that people are no longer able to undertake these activities within the municipality and/or that result in a significant loss of tourism related revenue to local businesses. A significant positive effect is one that

enhances tourism or recreational activities or brings additional revenue through these activities to local businesses.

7.14.4 Project Effects on Tourism and Recreation

The quarry development has the potential to affect the tourism and recreation in the following ways:

1. A decrease in wilderness/nature oriented recreation and tourism within the Project Area and vicinity (i.e., Affected Areas) due to marine vessel traffic and actual or perceived noise, dust and light from the quarry construction and operations. Visually, the quarry may deter boaters and kayakers from visiting this portion of the coastline. This in turn may negatively affect revenue at local campgrounds, rental accommodations and other service providers. A fuel spill in the marine environment would likely deter tourists and recreational users from visiting affected areas, possibly including nearby coastal areas.
2. An increase in expenditures on tourism services. Large development projects may hire staff from outside the immediate region and present employment opportunities to local residents who are currently seeking work. These people may choose to live relatively close to the quarry to minimize commuting distances. Increased populations in nearby communities including Fox Island Main, Upper Fox Island, Half Island Cove, Phillips Harbour and Canso would likely result in secondary economic benefits to these communities as new residents increasing frequent local tourism and recreational infrastructure and services. The magnitude of increased expenditures is difficult to estimate, but is generally related to:
 - The number of staff hired for the Project;
 - Recreational opportunities and services available in the immediate area; and
 - The duration of the Project.

In relation to other districts in Nova Scotia, the Eastern Shore of Nova Scotia accounted for only 7% of the visitors to Nova Scotia (2010 Nova Scotia Visitor Exit Survey). Of the 7% of tourists who visited the Eastern Shore, only 9% visited Guysborough and 18% visited Canso. This demonstrates that tourism is not a major source of revenue for these communities, although it no doubt plays a critical economic role to some local businesses. Similarly, demand on existing tourism and recreational services are relatively low. The main tourist locations are beaches, trails and parks. Recreational fishing in the Bay, especially for Bluefin Tuna, is also a popular tourist and recreational activity. Unfortunately, no similar data exist that describe the level of economic activity generated by local tourists; that is, by people visiting this area from Halifax, Cape Breton and other parts of Nova Scotia.

Currently, the coastal regions of the Project Area are occasionally visited by local residents who enjoy the beaches and undeveloped vistas (H. Krause, pers. comm. 2014). These areas are also used occasionally for recreational fishing. Because access to the terrestrial portions of the Project Area has historically been difficult, the Property is not consistently used for recreational purposes. An overgrown access trail connects Fox Island Main to Black Point, and ATV trails reportedly connect Upper Fox Island with residents on Half Island Cove Road (O. Rhynold, pers comm. 2014). Beaches, recreational fishing opportunities and hiking/ATV opportunities are relatively common within the municipality and so the loss of these opportunities within the Project Area itself is not considered a significant adverse effect.

The closest tourism and recreational facilities in the Affected Area are Lower Half Island Cove Beach, 1.70 km west, Eagle Valley and Hayden Lake Cottages, 880 m 980 m south, respectively, and Seabreeze Campground 3.3 km east. The potential environmental effects of dust, noise, and light trespass on these receptors are presented in Sections 7.1, 7.2, 7.3 respectively. In all cases, no significant adverse effects are predicted although noise and light may be perceptible from viewpoints to the east and west. With respect to Seabreeze Campground located over 3 km from the Project site, it is likely that Project related noise will be perceived as a component of ambient of background noise. This is not expected to affect attendance rates at the campground.

At peak operations there will be approximately 90 ships a year transporting material from the quarry; adding to the almost 600 large vessels (and an unrecorded number of fishing and recreational vessels) that are already present on an annual basis. Given that ships are a common sight in Chedabucto Bay, the presence of these additional vessels is not expected to cause a noticeable change to tourism and recreational use patterns in the Affected Area.

As noted in Section 7.13 (Local Economy, Land and Resource Use), a vessel fuel spill in the marine environment would likely result in changes to land use in the vicinity of spill over the short and medium term (estimated at 5-15 years). Depending on where the spill occurred and the volume of fuel released, people may refrain from boating in the area and visiting favourite beaches and headlands. This in turn would have negative economic consequences within Guysborough County.

As noted, the Project will employ 50-60 people full time at peak production. The majority of people employed will likely come from local communities and therefore no significant increase in population is expected. Nevertheless, these 50-60 new employees will likely spent a portion of their disposable income on recreational or tourism-type activities, equipment and services. While this expenditure may be noticeable to local businesses and so would be considered a positive Project effect, the increased expenditure is not considered to be a *significant* positive effect.

7.14.5 Mitigation & Monitoring

Since the effects from the Project under normal operating conditions on tourism and recreational activities are expected to be minimal, no specific mitigation or monitoring is proposed. The site entrance from Marine Drive will be equipped with a sign announcing the company and operations, while precautionary signs will be posted at appropriate locations along the property boundary and coastline warning recreational users of potential site and operational dangers.

With respect to a spill in the marine environment, navigational safety mitigation measures aimed at preventing vessel collisions and emergency response planning measures are presented in Section 7.18.3. Vessels will not be refuelled at the marine terminal; this helps to minimize the risk of fuel spills at the terminal. Vehicle fuel used at the quarry will be kept in double hulled reservoirs protected against collision. In the event of a spill on land, site drainage is directed south to the settling ponds rather than north to Chedabucto Bay. This in turn helps to contain any spills and allow them to be cleaned up.

7.14.6 Residual Effects & Significance

The significant residual impacts of the development are considered in the Table 7.14-1. No significant adverse effects to this VC.

**Table 7.14-1:
Residual Environmental Effects for Tourism and Recreation**

			Significance Criteria for Residual Environmental Effects						
Project-Environment Interaction	Potential Positive (P) or Adverse (A) Effect	Mitigation	Magnitude	Geographic Extent	Duration/Frequency	Reversibility (R=reversible NR=Non reversible)	Ecological/Social-cultural and Economic Context	Residual Effect	Significance
Construction									
Decrease in tourism on within the property boundary and Affected Areas	A	None	Low (1)	2 (1-10 km ²)	3/6 (2 years/continuous)	R	Area is affected by past human activity.	Minimal within County	Not Significant
Increase in tourism related expenditure	P	None	Low (1)	3 (11-100 km ²)	3/6 (2 years/continuous)	R	Area is affected by past human activity.	Positive	Not Significant
Operation / Decommissioning									
Decrease in tourism on within the property boundary and Affected Areas	A	None	Low (1)	2 (1-10 km ²)	5/6 (>6 years/continuous)	R	Area is affected by past human activity.	Minimal within County	Not Significant
Marine Fuel Spill	A	Implementation of navigational safety measures; Use of an Emergency Response and Spill Contingency Plan	Medium (2)	2 (1-10 km ²)	5/1 (>6 years/one time)	R	Area is affected by past human activity.	None anticipated	Not Significant

Increase in tourism related expenditure	P	None	Low (1)	3 (11-100 km ²)	56 (>6 years/continuous)	R	Area is affected by past human activity.	Postive	Not Significant
--	---	------	------------	--------------------------------	-----------------------------	---	---	---------	--------------------

Legend

Magnitude:

U= Unknown - An environmental effect affecting an unknown portion of a population or group or where the changes in a specific parameter are unknown.

0 = Nil - No environmental effect.

1 = Low (e.g., specific group, habitat, or ecosystem localized 1 generation or less, within natural variation)

2 = Medium (e.g., portion of a population or habitat, or ecosystem 1 or 2 generations, rapid and unpredictable change, temporarily outside the range of natural availability)

3 = High (e.g., affecting entire stock, population, habitat or ecosystem, outside the range of natural variation)

Geographic Extent:

1 = < 1 km²

2 = 1 – 10 km²

3 = 11 – 100 km²

4 = 101 – 1,000 km²

5 = 1,001 – 10,000 km²

Duration:

1 = < 1 month

2 = 1 – 12 months

3 = 13 – 36 months

4 = 37 – 72 months

5 = > 72 months

Frequency:

1 = < 11 events/year

2 = 11 – 50 events/year

3 = 51 – 100 events/year

4 = 101 – 200 events/year

5 = > 200 events/year

6 = continuous

Reversibility:

R = Reversible

I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or area not adversely affected by human activity.

2 = Evidence of adverse environmental effects.

7.15 COMMERCIAL FISHERIES

7.15.1 Overview

Marine commercial fisheries represent an important, sustainable resource of historical, cultural, social and economic value to local communities and Mi'kmaq. As noted, there are no *freshwater* commercial or recreational fisheries on the Property. At the same time, aquaculture is not currently practiced along the south shore of Chedabucto Bay. Freshwater fisheries and aquaculture are not discussed further in this section.

The primary species harvested on a commercial basis in Chedabucto Bay south of the established shipping lanes are:

- Lobster;
- Shrimp;
- Herring, Mackerel and Squid
- Snow Crab;
- Tuna; and
- Scallop

Sea urchin, rock crab, marine plants and eels are reportedly not fished on a commercial basis at this time, although local fishermen do have licenses that permit the harvest of these species. Mackerel is the primary salt-water recreational species in the area, but catch and release recreational bluefin tuna fishing is also popular.

The fisheries considered for this assessment include the commercially harvested finfish and shellfish listed above. For the purposes of this section, the term “fish” and “fishing” generally refers to all species mentioned above unless the context suggests otherwise.

7.15.2 Boundaries

7.15.2.1 Temporal Boundaries

Impacts to commercial fishing are expected while the marine terminal is being constructed (24 months) and operated (45 years). Decommissioning activities will be short-lived (12 months although this may be extended if needed) but may also interfere with commercial fishing.

The temporal boundaries also consider the different fishing seasons since these are the times when commercial fishing occurs within the spatial boundaries defined for the EIS.

7.15.2.2 Spatial Boundaries

The spatial boundaries for Commercial Fisheries are similar to those identified for Marine Species and Habitat. Assessment boundaries divided into the Project Area, the Affected Area and the Study Area.

For the Commercial Fisheries VC, the Project Area is defined as the limits of the proposed seabed Crown lease that will be needed to construct the marine terminal (Section 1.0 and Figure 4.0-1). The Crown lease boundaries will entirely contain the marine terminal.

The Affected Area is the nearby zone that could potentially be affected by Project activities. For this VC, the Affected Area is a zone around the marine terminal where lobster fishing will be restricted for safety considerations as ships access and berth at the terminal.

The Study Area is the larger zone in Chedabucto Bay where other types of Project-environment interactions may occur. In this case, the Study Area is defined to include the proposed ship travel routes between the marine terminal and the established shipping lanes in Chedabucto Bay, as shown on Figure 3.29. This zone is chosen since it defines an area within which Project-related shipping may interfere with commercial fishing activities.

7.15.2.3 Administrative Boundaries

Commercial fish harvesting is managed and regulated by Fisheries and Oceans Canada, a federal agency, under the *Fisheries Act* and its enabling regulations. From the provincial perspective, the *Fisheries and Coastal Resources Act* regulates recreational fishing, sea plant harvesting, licensing of fish buyers and processors, and aquaculture.

Administrative boundaries applicable to commercial fisheries include the fishing area boundaries and districts, as well as fishing seasons imposed by regulation on commercial fishermen. These boundaries are described in Section 6.10.

7.15.2.4 Technical Boundaries

To protect the confidentiality and economic livelihood of fishermen, species landing data reported by individual fishermen is “aggregated” into larger datasets that tend to conceal exactly where fish and other species are caught, and how much of each species is landed. According to DFO, each unit of data released consists of a minimum of five license holders, vessels and buyers. This means that only generalized fishing trends are available as a basis for descriptions of Project impacts.

7.15.3 Threshold for Determination of Significance

A Project-related significant adverse effect on commercial fisheries is one that causes:

1. an uncompensated loss of habitat of those fish species that are used for, or support commercial, recreational and/or Aboriginal fisheries; or
2. a sustained decrease in earnings from a fishery due to lower catch quantity and/or quality, or increased fishing costs (i.e., due to longer travel times, loss of gear, additional license fees, etc.).

7.15.4 Effects of the Project on Commercial Fisheries

The presence and use of the marine terminal will result in limitations to lobster harvesting in the immediate area and, as a result, displacement into other areas of those who currently fish in the nearshore at the Black Point site. This limitation will occur for two reasons: (1) the construction of the marine terminal will remove approximately 1.0 ha of lobster habitat that is currently available for commercial exploitation, and (2) fishermen will likely steer clear of the active marine terminal for safety and out of concern for gear losses. The marine terminal itself is not expected to significantly interfere with marine navigation.

Potential sediment-laden water runoff from terrestrial construction activities and consequent negative effects to water quality may displace fish from the immediate near shore but is unlikely to result in their death.

The transit of empty and loaded aggregate transport vessels has the potential to interfere with other commercial fishing activities that occur in deeper water between the established shipping lanes and the south shore of Chedabucto Bay. Once construction is complete, Project-related ship traffic will begin at a relatively modest rate of about 30 ships per year (less than 3 ships per month), increasing to about 90 ships per year once full capacity is reached after approximately 10 years (provided market conditions support this rate). This is equivalent to about one ship every four days or so. In addition to interference with on-going fishing, noise associated with this increased traffic may displace fish from the immediate area.

The added ship traffic (consisting of aggregate transports, tugs and pilot vessels) may require fishermen who frequent deeper water to avoid preferred fishing grounds to accommodate Project-related ship traffic. The deep water shrimp fishery concentrated along the edge of the established shipping lane is reportedly vulnerable to displacement since fishermen are currently exploiting all the available shrimp grounds.

Accidental fuel spill or other discharges to the aquatic environment can alter water quality and physical habitat, which in turn can negatively affect life-cycle stages of commercially important species and their food supply. Accidental aggregate spills will not likely affect the commercial fishery since this material has already been washed to remove fine-grained sediment. Granite itself is chemically inert and is common in Chedabucto Bay.

Effects of decommissioning the marine terminal will be similar to those expected during construction, except that it is likely the marine terminal will be left in place rather than removed. Surface structures such as the access road and slewing arm may be removed for safety and security but work associated with this removal will be of temporary duration.

No impact is expected to the fixed berth mackerel, herring and squid trap fisheries since these berths are considerably removed from the Project site (Section 6.10). A possible exception to this are the two mackerel traps located in Indian Cove approximately 4.0 km east of the marine terminal. Concerns have been raised by local fishermen that the marine terminal will divert mackerel from their normal coastal-hugging route that brings them into Indian Cove where the traps are located. Instead, the terminal may encourage the fish to remain offshore and travel directly from Black Point to Fox Island, rather than entering Indian Cove.

Consideration is also made for the Mi'kmaq First Nations which have recognized rights to the commercial or livelihood fishery. It is understood that any impacts that could result in an uncompensated loss in habitat, or in loss of sustained earnings in the livelihood fishery must be addressed with respect to the impact on Mi'kmaq rights.

Mi'kmaq livelihood fishing is managed in accordance with the regulatory procedures used by DFO for the non-aboriginal commercial fishery: the existing baseline conditions for the commercial fishery are shared with the Mi'kmaq livelihood fishery (seasonality, license conditions, quotas etc.). As a result, the current baseline conditions for the livelihood fishery are the same as those of the commercial fishery.

Although the Mi'kmaq Band Fisheries Departments have reported that there is currently no livelihood lobster fishery activity, or food, social and ceremonial lobster fishing activity in the waters near the Project site at this time, effects on the commercial fishery in the area may have an impact on the right to access the fishery. Therefore it is important to maintain ongoing communication with Mi'kmaq First Nations throughout the Project and during decommissioning. This communication will be through direct dialogue.

It has been noted that the principle livelihood fishery in the area is the commercial shrimp trap fishery. Concerns have been raised by non-aboriginal fishermen that ship movements may interrupt or temporarily displace shrimp trap fishing operations. This spatial conflict has been resolved through dialogue between the Proponent and local area shrimp fishermen, with the result that vessel activity near the marine terminal will avoid preferred shrimping grounds to the extent this is possible, practical and safe.

Mi'kmaq fishing, hunting and gathering activities can be impacted by the cumulative effects of multiple projects (Section 9.0). However, it is likely that the cumulative effects of the identified projects in the area will have little impact on the Mi'kmaq fishery and wildlife harvesting in the Project area. It is possible that there could be a positive cumulative impact on social condition of Mi'kmaq harvesters as multiple projects are undertaken that might provide useful and necessary employment for Mi'kmaq marine and environmental skills at several ongoing project sites.

7.15.5 Mitigation & Monitoring

7.15.5.1 Mitigation

The scale of marine terminal construction impacts to commercial fisheries will depend in part on the seasonal timing of in-water work. Impacts will be greater if marine terminal construction occurs during lobster season, which runs from April 29 to June 30. The area occupied by the marine terminal is reportedly fished by only two or possibly three fishermen since appropriate lobster habitat is limited to relatively shallow depths in the immediate nearshore. Off the Black Point property, the water deepens rapidly and the bottom changes from rocky to muddy substrate, which is less preferred by lobster.

The primary mitigation measure is to minimize impacts during construction through the use of standard best management practices for terrestrial and in-water construction. Standard construction best management practices and mitigation measures to control onshore sediment release to the marine environment will be implemented. These measures are described in Section 7.6 and Section 7.11.

The effects of increased ship traffic will be mitigated by ensuring fishermen and the local traffic authority is aware of Project-related vessel traffic with sufficient advance notice to redeploy gear elsewhere as needed. At the same time, regular and on-going communication from fishermen who routinely fish in areas that will likely be transited by Project vessels would be helpful to limit unnecessary changes to fishing habits and accidental interactions between Project vessels and fishing gear. Communication regarding ongoing fishing practices can be used by pilots and ship masters to avoid particular fishing areas at all times, during certain times of the fishing season, or for certain weeks of a specified month. To aid this two way communication, local fishermen will be encourage to call the quarry site office, which will be manned 24 hours per day, in order to receive updates regarding vessel arrivals and departures.

Vessels regularly transit Chedabucto Bay safely and effectively with the help of pilots who understand the navigational hazards of the Bay, using communication with shore based traffic oversight facilities, and through the use of established shipping lanes and navigation protocols. Should Project-related vessel traffic or construction result in fishing gear damage or loss, this loss can be reported to the quarry site office.

Construction and regular use of the marine terminal will likely require a safety exclusion zone around the terminal. The loss of fishing access will no doubt mean that lobster can no longer be harvested from this nearshore area. However, this area is quite small (1.1 ha not

including the estimated safety zone) and preliminary discussions with lobster fishermen have indicated that considerable opportunity to create lobster habitat in the nearshore exists immediately adjacent to (both east and west of) the Project site.

The marine terminal will be equipped with lights and fog horns as required for safety by Transport Canada. These aids will effectively mitigate any navigation concerns.

Mitigation for loss of fish habitat is detailed in Section 7.11. A Fisheries Offset Program will describe the work that will be undertaken to create new lobster habitat along the south shore of Chedabucto Bay. Mitigation measures must also ensure that impacts on Mi'kmaq rights to food, social and ceremonial and livelihood fish harvesting are addressed. As part of the above, the Project will maintain formal and routine communication with Mi'kmaq First Nation representatives to determine the effectiveness of mitigation measures on the specific impacts on Mi'kmaq food, social, ceremonial and livelihood harvesting that may be identified during Project activities. Routine communication protocols will be established under the terms of the Collaborative Benefits Agreements.

Furthermore, potential impacts on livelihood fishing activity will be a focus of discussion in the Community Liaison Committee to which Mi'kmaq representatives have been invited as committee members.

Summary

During the construction phase, efforts to reduce or mitigate effects to commercial fishermen will include (a) on-going communications between the Proponent and representatives of the local fishing community; (b) completing the marine terminal construction outside of lobster fishing season (i.e., for the late summer, fall, winter and early spring) to the extent possible; (c) complying with well-established navigation safety procedures; and (d) addressing claims regarding gear damage and loss and when appropriate, providing compensation. With the implementation of these measures, significant adverse effects on commercial fisheries due to construction of the marine terminal are therefore not anticipated.

Exclusion from fishing grounds due to incoming or outgoing vessels will be mitigated through ongoing communication between fishermen and the vessels. Provided communication is regular, on-going and two-way, impacts associated with commercial fisheries other than lobster are expected to be not significant. The potential effect on overall catch harvest and the cost of fishing is from vessel interference is anticipated to be insignificant, but will be addressed through consultation with the marine fisheries authorities and the local fishing community. The Proponent will inform local fishermen and other vessel captains of the location and scheduling of activities and other potential hazards through issuance of *Notices to Mariners*, as required by applicable regulation. Provided these mitigation measures are implemented on an on-going basis, no significant adverse impacts to commercial fisheries are predicted.

7.15.5.2 Monitoring

Monitoring of the effectiveness of the marine Fisheries Offset Program will be undertaken for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met. Terminal operations and fishing access will be monitored in response to concerns expressed by the local fishing community, as needed. In future consultation with the GCIFA, the Proponent will consider participating in the comprehensive and extensive fisheries data collection programs currently undertaken by the GCIFA.

7.15.6 Residual Effects & Significance

Provided the recommended mitigation measures are implemented and claims for compensation due to gear damage or loss are addressed in a timely and effective manner, no significant adverse residual environmental effects on commercial fisheries are likely to occur. Table 7.15-1 provides a summary of the residual environmental effects and recommended measures for the Commercial Fisheries VC.

**Table 7.15-1:
Residual Environmental Effects for Commercial Fisheries**

Project Environment Interaction	Potential Residual Environmental Effects A = Adverse P = Positive	Mitigation	Magnitude	Geographic Extent	Duration / Frequency	Reversibility	Ecological / Socio-Economic Context	Residual Effect	Significance of Residual Impacts
Construction									
Marine terminal construction: noise and suspended sediments causing fish avoidance;	A	• See Mitigation above	1 (low)	2 (1-10km ²)	3/1	R	1	Temporary avoidance	Not Significant

Magnitude:

U= Unknown - An environmental effect affecting an unknown
portion of a population or group or where the changes in a
specific parameter are unknown.

0 = Nil - No environmental effect.

1 = Low (e.g., specific group, habitat, or ecosystem localized 1
generation or less, within natural variation)

2 = Medium (e.g., portion of a population or habitat, or ecosystem
1 or 2 generations, rapid and unpredictable change, temporarily
outside the range of natural availability)

3 = High (e.g., affecting entire stock, population, habitat or
ecosystem, outside the range of natural variation)

Geographic Extent

1 = < 1 km²

2 = 1 – 10 km²

3 = 11 – 100 km²

4 = 101 – 1,000 km²

5 = 1,001 – 10,000 km²

Duration:

1 = < 1 month

2 = 1 – 12 months

3 = 13 – 36 months

4 = 37 – 72 months

5 = > 72 months

Frequency:

1 = < 11 events/year

2 = 11 – 50 events/year

3 = 51 – 100 events/year

4 = 101 – 200 events/year

5 = > 200 events/year

6 = continuous

Reversibility:

I = Irreversible

Ecological / Socio-Economic Context:

1 = Relatively pristine area or
area not adversely affected
by human activity.

2 = Evidence of adverse
environmental effects.

N/A = Not applicable

A = Adverse

P = Positive

7.16 ARCHAEOLOGICAL AND HERITAGE RESOURCES

As defined by the Nova Scotia Department of Communities, Culture and Heritage, an archaeological resource is:

“a work of past human activity, or zoological, botanical, geological or other natural materials found in association with such activity that:

(i) is primarily of value for its prehistoric, historic, cultural or scientific significance; and,

(ii) lay on, or was buried or partially buried in land in the province, including land covered by water.”

Archaeological and Heritage Resources were identified in the EIS Guidelines as a potential VC as concerns have been raised regarding the possible existence of these resources during the public outreach phase of the environmental assessment.

A 2011 Archaeological Resource Assessment survey did not identify any archaeological or heritage resources, but potential post-European contact resources were identified on the Property near the coast during the 2014 Archaeological Resource Assessment (Section 6.12 and **Appendix L**). Although 30 m buffer zones will be left undisturbed along the coastline, (thereby protecting some of these finds), much of the coastal zone inside this buffer will be built upon, thus potentially disturbing, destroying or covering over some of these resources.

Details of archaeological and heritage resources existing conditions on the Project site are presented in Section 6.12.

7.16.1 Boundaries

7.16.1.1 Temporal Boundaries

The temporal boundaries for the assessment of impacts upon archeological and heritage resources are limited to the construction phase of the development. Construction is estimated to take two to three years. An adverse effect on an archeological or heritage resource would be permanent.

7.16.1.2 Spatial Boundaries

The spatial boundaries for the assessment of impact on archeological and heritage resources are limited to the terrestrial portion of the Project Area, particularly the coastal areas. The inhospitable nature of the barrens suggests that little cultural activity, whether Pre-contact or historic, would have occurred in the central portion of the Project Area.

7.16.1.3 Technical Boundaries

No technical boundaries were identified for the Archeological and Heritage Resources VC.

7.16.1.4 Administrative Boundaries

Nova Scotia's *Special Places Protection Act* governs archaeological surveys in Nova Scotia. In order to conduct any archaeological work a Heritage Research Permit issued by the Minister of the Department of Communities, Culture and Heritage must be obtained.

7.16.2 Threshold for Determination of Significance

Based on the existing information for the area, the Project may interact with some areas considered to hold a high potential for documented and/or undocumented archaeological resources. If archaeological resources are identified within the Project Area, a significant adverse effect is defined as an uncontrolled disturbance to, or destruction of, any such resource considered by the Mi'kmaq, provincial regulators or local residents to be of major importance.

7.16.3 Effects Archaeological and Heritage Resources

7.16.3.1 Construction

There is potential for the loss of archaeological resources in preparation of the site for construction, during the clearing, grubbing and grading phase of the Project. Artefacts may be encountered on the lower coastal platform as described in Section 6.12.

7.16.3.2 Operation

There is no potential for the disturbance of archaeological or heritage resources during the operational phase of the Project.

7.16.3.3 Decommissioning

There is no potential for the disturbance of archaeological or heritage resources during the decommissioning phase of the Project.

7.16.4 Mitigation and Monitoring

7.16.4.1 Mitigation

Exploratory excavation will likely be required in those areas that may be disturbed during Project construction. This excavation work will be undertaken under the direction of experienced archeologists before construction begins. At the same time, potential heritage resources identified during the 2014 study that will not be disturbed by construction will be flagged to ensure they are not accidentally affected by construction activities.

Prior to beginning construction, the Proponent will implement a Cultural Resource Management Plan to guide site personnel in the event that archaeological and heritage resources are identified during construction. An example of this plan is provided in **Appendix L** as an attachment to the 2014 Archaeological Resource Assessment.

The Cultural Resource Management Plan specifies a notification procedure if remains are found, and will describe resource specific preservation measures as needed. This may include archaeological excavation or avoidance of the site. These mitigation measures would be

approved by the Minister of the Department of Communities, Culture and Heritage before site construction could begin. This Plan is considered a standard mitigation measure applied at construction site with cultural heritage or archaeological potential

7.16.4.2 Monitoring

The Project archaeologist will be informed with respect to construction starting dates and progress. During initial construction phases, the archaeologist will be on “standby” and may visit the site from time to time as needed.

7.16.5 Residual Effects and Significance

The results of the effects assessment for the archaeological resource VC is provided in Table 7.16-1.

With application of resource specific mitigation measures outlined in the Cultural Resource Management Plan, no significant adverse effects to these resources are likely.

**Table 7.16-1:
Residual Environmental Effects for Archaeological and Heritage Resources**

		Significance Criteria for Residual Environmental Effects								
Project-Environment Interaction	Potential Positive (P) or Adverse (A) Effect	Mitigation	Magnitude	Geographic Extent	Duration/Frequency	Reversibility (R=reversible NR=Non reversible)	Ecological/Social-cultural and Economic Context	Residual Effect	Significance	
Construction										
Damage to or destruction of cultural resources.	A	<ul style="list-style-type: none">• Undertake exploratory excavation to document and conserve resources prior to construction• Flag and buffer heritage resources so that will not be disturbed during construction• Implement a Cultural Resources Management Plan in the event that other heritage resources are revealed during constructions	Low	Limited to the lower coastal platform of the Project footprint (about 30 ha).	Permanent / one time but avoidable with mitigation	NR	Area is affected by past human activity.	None Anticipated	Not Significant	
Operation / Decommissioning										
None expected										

7.17 ABORIGINAL LAND AND RESOURCE USE

The MEKS prepared for this environmental assessment (**Appendix K**) highlights the Mi'kmaq Nation's long-standing relationship with, and attachment to, the region in and around the Project site. The region holds historical significance to the Mi'kmaq nation and to the development of relationships between European settlers and the Mi'kmaq. While the Project area is not home to present day Mi'kmaq communities, it was in this region that Mi'kmaq demonstrated local hunting, trapping and gathering practices to newcomers, thus fostering a lasting relationship of peace and friendship with the French, and eventually other European inhabitants of the *Eskikewa'kik* area. This intimate relationship between the Mi'kmaq and the region is demonstrated with the extensive awareness of flora and fauna resources in the Project area despite the interruption in use of the area due to development and national Aboriginal policies. The existence of numerous species of plants, fish, and game in the Project area that are known to be culturally significant to Mi'kmaq is evidence that the site was likely used by the ancestors of today's local Mi'kmaq communities.

Based on the findings of community wellbeing studies conducted by Aboriginal Affairs and Northern Development Canada, the well-being index score for Mi'kmaq communities is well below average index values for local non-aboriginal communities (O'Sullivan 2011). The average Nova Scotia Mi'kmaq income index is 41/100, education is 41, housing is 72, and labour force activity is 66 with an overall community wellbeing index value of 55, which is well below the Atlantic region wellbeing average of 73. Since employment and income levels are below average, many families augment food supplies through hunting and fishing.

This is consistent with traditional and historical practice since Nova Scotian Mi'kmaq communities have always been highly dependent on natural resources. Fisheries and hunting played an important role in the annual community cycle, with communities migrating between their summer and winter encampments and the associated area harvests being divided between food, ceremonial, and commercial purposes (Stiegman 2006). This dependence was the foundation for the cultural relationship with the environment referred to as *Netukulimk*, a Mi'kmaq concept that relates to making a livelihood from the land through resource harvesting which does not jeopardize the integrity, diversity, or productivity of the environment (Doyle-Bedwell and Cohen 2001). There was an easy transition into a livelihoods fishery after colonization, as fishing was historically among the essential seasonal activities of the Mi'kmaq (Notzke 1994).

Traditionally, Mi'kmaq rights relating to decision-making over natural resources were not vested in a hierarchical leadership but rather were made through a consensus of all members of the community (Milley and Charles, 2001). This approach to management was eroded over time as a result of government policy and practices. Furthermore, passive exclusion of First Nations from mainstream economic activity resulted from governmental limitations on access to the fishery (as well as forestry and other resources) which resulted in little, if any, economic benefit (Wiber and Milley 2007).

This has resulted in the below average economic condition (as noted above), and while First Nations are provided with various social services and programs (including housing, education and health), program deliver has not kept pace with demand and these communities and many First Nation communities remain well below Canada's accepted national standards.

However, improvements to resource access have come about over the past two decades through the avenue of aboriginal rights, as a result of decisions of the Supreme Court of Canada. In particular, the Marshall decision has led to significantly increased involvement of Mi'kmaq First Nations in commercial fishing activities, through the issuance of communal commercial licenses. Being communal in nature, a community can manage these commercial licenses not only in the interests of those who are fishing, but also to provide benefits across the community.

As noted in section 6.10.4, several Mi'kmaq communities are currently fishing marine species for livelihood purposes along the eastern shore. Of these, only the Waycobah shrimp trap fishery is operating in proximity to the Project where Project-related impacts may be anticipated. The Waycobah band holds the only Mi'kmaq shrimp trap license in the south side of Chedabucto Bay however this license is currently being fished by non-aboriginal license holders on behalf of the Band where the allocated traps are divided among several local non-Mi'kmaq fishermen (G. Boudreau, pers. comm. 2015). In addition, no Mi'kmaq fishermen currently deploy lobster traps in the Project vicinity (G. Boudreau, pers. comm. 2015) although they, like other LFA 31 license holders, have the right to fish anywhere within LFA 31.

Shrimp and other fisheries are managed under the Department of Fisheries and Oceans through communal commercial licenses, some of which are issued for the large fishery management areas along the Nova Scotia eastern shore. Given this, there is no defined "Mi'kmaq fishery" as such.

As noted in section 6.10.4, there is currently no direct Mi'kmaq use of the Project site for subsistence harvesting of food or furbearing in animals. However, as noted in the MEKS (**Appendix K**), based on archival research and interviews with key knowledge holders there is:

1. potential for the disturbance of hitherto unidentified archaeological resources during the construction of the infrastructure (access road, processing facility, shipping terminal) associated with the Project, as well as the quarry operation itself.
2. likely permanent loss of wildlife and plant resources which have been traditionally harvested within the immediate project footprint. This loss is likely the result of the physical removal or displacement of specimens during construction and operation of the quarry, or restriction of access to the location as a potential harvesting area.
3. potential harm or dispersing of local wildlife due to noise disturbance resulting from increased human presence, vehicular traffic, blasting, and general mining activities.
4. potential disturbance or contamination of vegetation, wetlands and water bodies within the corridor along the access road, and within the area of the quarry pit as well as the shipping terminal as a result of settlement of dust and other airborne pollutants created during the mining, crushing and transport of the product. This can depreciate the quality of local food and medicinal plants for human consumption as well as the quality of animal browse and water/wetland habitat.
5. potential degradation of the local marine and shoreline habitats surrounding the shipping terminal due to dust contamination, the potential for accidental aggregate spillage during loading, and possible contamination resulting from accidental spills of petroleum products associated with cargo vessels.

The nature of Mi'kmaq cultural connection with traditional resource harvesting activities suggests that environmental effects on fish, plants and wildlife can create associated socio-cultural and/or socio-economic effects. These can lead to disconnection with traditional food sources thus increased dependence on non-traditional foods and general community frustration and anger due to cultural erosion/assimilation.

7.17.1 Boundaries

The boundaries of the potential environmental effects vary from ecosystem and socio-economic perspectives. The Affected Area includes all lands and waters that are *potentially* used by the Mi'kmaq for traditional harvesting purposes, and which could be affected by the Project via light, noise, dust or other emissions. In this respect, the Project boundaries for the Aboriginal Land and Resource Use VC are identical as those described for each biophysical component in the previous sections. Generally speaking however, the environmental effects (1 to 5 above) are bounded within the Project site, or in close proximity to the project Site since there is currently no active traditional harvesting on the Project site or in the immediate vicinity.

The boundaries for the social, health, cultural, and socio economic effects are wider in geographical scope. These effects include the Mi'kmaq families who have been involved with resource harvesting in the region, and their communities. The boundaries include the Mi'kmaq communities discussed in section 6.9.3.

7.17.2 Threshold for Determination of Significance

The threshold for determination of significance of the social, cultural and economic effects is determined through ongoing discourse with Mi'kmaq representatives. Since Project effects can be considered as a matter of Rights to harvest food, social and ceremonial resources, and Treaty Rights to harvest natural resources, including plants, fish and wildlife for a moderate livelihood the threshold for determination of significance is a matter of consideration by the Crown and Mi'kmaq representatives (Assembly of Nova Scotia Chiefs and the Governments of Canada and Nova Scotia).

Project effects resulting in the loss of employment and income for Mi'kmaq fishers that could not be replaced within a reasonable time, loss of food resources upon which Mi'kmaq families depend that could not be found in reasonable proximity to communities, or permanent loss of cultural relationship caused with the lands, flora and fauna directly by the Project would be significant. Non-permanent or geographically limited (i.e., small scale) changes in harvest areas caused by displacement due to Project activities are not considered to be significant.

7.17.3 Effects on Aboriginal Land and Resource Use

In addition to the environmental considerations discussed below, Mi'kmaq culture is valued greatly in NS. Many Mi'kmaq continue to pursue elements of a traditional lifestyle, spending time in the country harvesting fish, game, berries, and firewood. Mi'kmaq land/resource use and culture could be affected by the Project development through such effects as the loss or alteration of harvesting areas and reduced access to traditionally used lands. Aboriginal land claims can affect the establishment of clear title for land designated for industrial development and exclusive use. Both Federal and Provincial Governments have responsibilities with respect to Aboriginal peoples and the settlement of outstanding land claims. Consideration of Aboriginal interests is legislated by federal and provincial laws.

While presently there is limited involvement of Mi'kmaq individuals in the Project site, it was clearly evident that the region had been used in the past (within living memory) for food gathering and recreation. The decision to continue to use this area has been affected by a number of historical factors (most significantly centralization policies to move Mi'kmaq families to reserves) and demographic factors. A rapidly growing youth population that is pursuing education and alternative training has resulted in a slight de-emphasis on hunting within the rapidly growing communities (it is possible that firearms regulations and hunter training requirements may be a contributing factor in the decline in hunting amongst Mi'kmaq youth).

It is also clear from the research that, traditionally, decisions related to food, social and ceremonial fishing and hunting has been based on opportunistic access to food resources that are most abundant in close proximity to reserve communities and urban residential areas. As a result, there may be future interest in fishing, hunting and possibly gathering in the Project area as land-use changes, and increased urbanization and other developments impact areas currently used by Mi'kmaq hunters and fishers. In keeping with traditional decision-making practices, an important attribute of the ecological knowledge system, areas such as the Project site would logically be considered for harvesting activities due to its easy access from Nova Scotia's transportation routes.

It has been noted during the engagement activities that several Mi'kmaq communities have access to the waters adjacent to the project site for livelihood fishing. While these licenses fall under the management plans and regulatory control of the Department of Fisheries and Oceans, access to the commercial fishery by Mi'kmaq harvesters is founded in the Treaty Rights held by the Mi'kmaq nation. Mi'kmaq which has been involved in the local groundfish, lobster, snow crab, tuna, swordfish, and mackerel fisheries include: Acadia, Potolotek, Eskasoni, Sipekne'katik, Membertou, Millbrook, Wagmatcook, Waycobah, Pictou Landing and Paqtnkek.

Potential Project-related effects on the natural environment and land resources with potential significance for Mi'kmaq interests are listed in Table 7.17-1. The table includes mitigation measures aimed to minimize the overall ecological effects of the Project on the site and adjacent lands. The Proponent is committed to addressing Mi'kmaq interests, minimizing possible adverse Project effects, and maximizing Project benefits in a collaborative approach to Project planning and development (see Section 11). This is expected to include all phases of the Project.

While there is currently no Mikmaw harvesting on the site or in waters immediately adjacent, it is intended that the Project site and adjacent waters will be accessible to Mi'kmaq for safe harvesting for flora and fauna for food, social and ceremonial purposes, in accordance with provincial and federal regulations. Any future potential Project impacts (environmental, social and economic) on these harvesting activities will be a matter of the formal and regular meetings with the Mi'kmaq community representatives in accordance with the terms set in the Collaborative Benefits Agreements.

**Table 7.17-1:
Potential Impacts on Mi'kmaq Interests**

Potential Impacts	Assessment of Significance	Mitigation
Construction		
Disturbance of archaeological Resources.	<ul style="list-style-type: none"> Archaeological resources are irreplaceable and of extreme importance. Being the only source of information on Mi'kmaq pre-contact history, land use, occupancy and culture, archaeological information from the site should be preserved and protected. 	While there has not been a confirmed Mi'kmaq archaeological significance of the Project site, observations will be maintained during all construction activity and should evidence be uncovered all activity will cease in the area until Mi'kmaq archaeological experts have had an opportunity to examine the site and determine appropriate action.
Permanent loss of wildlife and plant resources within the immediate Project footprint.	<ul style="list-style-type: none"> The species of significance to Mi'kmaq communities identified within the Project areas, in particular medicinal plants, are also present within the surrounding areas. The permanent loss of some of (or access to) these specimens within the Project area is not expected to significantly limit Mi'kmaq use of these resources. 	Efforts will be made to minimize the potential impact by containing all activity to within the Project footprint. Transferring significant flora and fauna to suitable nearby habitat will be implemented if warranted and feasible as determined through ongoing dialogue with Mi'kmaq communities
Construction, Operation and Decommissioning		
Noise disturbance will adversely impacts local wildlife resources.	<ul style="list-style-type: none"> Increased sound levels resulting from construction activities can interfere with hunters in areas of significance to Mi'kmaq. Because of the local nature of these impacts, their significance on local Mi'kmaq harvesting activities is limited. 	Noise mitigation will include measures noted in Section 7.2.
Contamination of surrounding vegetation, wetlands and water bodies through dust and other airborne pollutants.	<ul style="list-style-type: none"> The level of depreciation of local food and medicinal plants for human consumption is determined to be not significant, as are the impacts of a deteriorating quality of animal browse and water/wetland habitats on local fish and wildlife. Even though the radius of these impacts will undoubtedly extend beyond the boundaries of the Project area, their effects on individual Mi'kmaq resource activities is expected to be limited. 	Predicted ground level dust concentrations outside the Property will remain well within applicable air quality standards (Appendix O). Appropriate mitigation measures have been defined in Section 7.1.

Potential Impacts	Assessment of Significance	Mitigation
Contamination of marine and shoreline habitats surrounding the shipping terminal through possible fuel, oil or waste discharge associated with Project related vessel traffic or particulate run off from the project site.	<ul style="list-style-type: none">• Potential impacts of such may be wider-ranging depending on factors such as the nature of the accident/spill, season and marine currents. The significance of such potential impacts on the Mi'kmaq fishery is undetermined, however, based on the apparent current lack of use of the area for food, social and ceremonial fisheries harvesting, it is assumed that any effects will have negligible effect on current Mi'kmaq FSC fish harvesting.• Impacts of particulate run off have been considered and are expected to be negligible since runoff will be directed to sedimentation ponds for treatment prior to discharge.	Considerations for avoidance and reducing the risk for accidents and malfunctions have been an integral part of the work on design, construction and operation of the Project. This is outlined in Section 7.18, where appropriate mitigation measures are described.

7.17.4 Residual Effects and Significance

The residual effects of the Project on Mi'kmaq land and resource use activities are considered to be of minor significance. However, as noted in Table 7.17-2 below, some residual effects may have greater significance which can be mitigated through monitoring and communication.

**Table 7.17-2:
Residual Effects and Significance**

Residual Effect	Significance
Permanent loss of wildlife and plant resources which have been reportedly traditionally harvested within the immediate Project footprint; loss of future opportunities to harvest these resources.	Minor significance. The effects are localized only to the Project site and will not likely have widespread impact on regional resource abundance and distribution.
Harm to, or dispersion of local wildlife due to noise disturbance	Minor significance. The effects of noise on fauna can modify local behaviour (often a temporary effect as many species will acclimatize to anthropogenic noise). As above, noise effects will not likely have widespread impact on regional resource abundance and distribution.
Potential depreciation of the quality of local food and medicinal plants for human consumption due to disturbance, or contamination of vegetation, wetlands and water bodies within the Project site	Medium significance. The effects of contamination may result in permanent loss of harvest areas which will not likely have widespread impact on abundance, but could potentially create health risk for people using, or consuming food resources that occupy the Project site. Ongoing monitoring and communication with Mi'kmaq harvesters through representative organization can mitigate this risk.
Potential degradation of the local marine and shoreline habitats surrounding the shipping terminal related to dust contamination, the potential for accidental aggregate spillage during loading, and possible contamination resulting from petroleum products associated with cargo vessels	Medium significance. As above, environmental contamination of local fish and shellfish harvesting areas traditionally used by Mi'kmaq can pose a health risk. Ongoing monitoring and communication with Mi'kmaq representative organizations can mitigate this risk.
	Since Mi'kmaq exercise their rights to livelihood fisheries in accordance with the DFO Regulatory procedures for commercial fisheries, widespread effects on the Mi'kmaq coastal commercial fisheries will be the same as non-aboriginal commercial fisheries. This is determined as being of minor significance as the area is not considered to be critical habitat for commercially important species.

7.18 CHANGES TO COMPONENTS WITHIN FEDERAL JURISDICTION

7.18.1 *Environmental Effects Within Federal Jurisdiction*

As stipulated in the EIS Guidelines, this section summarizes those changes to the environment that may be caused by the Project on environmental components listed in paragraph 5(1)(a) of CEAA, 2012, namely fish and fish habitat as defined in the *Fisheries Act*, aquatic species (marine plants) as defined in the *Species at Risk Act* and migratory birds as defined in the *Migratory Birds Convention Act, 1994*. The material presented here is summarized from the sections above.

Freshwater Species and Habitat

There is no freshwater fish habitat present on the Black Point property. For the purposes of the EIS, Reynolds Brook located 1.0 km south of the Property is assumed to support freshwater fish and fish habitat. Full quarry development will reduce Reynolds Brook inflows by approximately 18%. This change to the environment may impair fish survival during dry periods and/or improve habitat quality by reducing inflows of low pH surface water to the Brook. This in turn may positively or negatively change the risk of fish mortality in Reynolds Brook, and/or result in changes to habitat quality and use. The effects and Accidents and Malfunctions will not be felt in Reynolds Brook since these effects would be contained within the quarry pit, which ultimately discharges north through the sedimentation ponds rather than south to Reynolds Brook.

With the implementation of the mitigation measures described in Section 7.10.5.2, including the creation of a 30 ha lake following cessation of quarrying activities, the residual impacts to freshwater fish and fish habitat are predicted to be not significant.

Marine Species and Habitat

The potential Project-related effects associated with this VC are presented in section 7.11.4 and include:

- Reduced habitat quality and habitat function due to altered water and sediment quality from sediments introduced to the marine environment during construction and operation.
- Reduced habitat for fish that are part of or support commercial, recreational or Aboriginal fisheries resulting from construction of marine terminal.
- Fish mortality due to the use of explosives within the pit; behavioural changes to fish, crustaceans and other marine species due to noise and vibrations associated with explosives use.
- Mortality (marine plants, benthic and pelagic organisms, etc.) and/or the loss of benthic habitat due to aggregate spills when the ships are loaded.
- Increased disturbance to marine flora and fauna and reduced habitat quality and function for marine species due to noise and vessel movement from increased ship traffic.
- Invasive species that may be introduced through the illegal discharge of ballast water.

In summary, these Project effects, as well as those resulting from an accidental fuel spill in the marine environment, may result in changes to the risk of mortality or injury to fish, marine mammals and/or marine plants and changes to habitat quality and use.

To address these potential effects a series of mitigation measures are proposed in Section 7.11.5 for implementation during construction and operations. Following the application of these measures, including the replacement of lobster habitat in the immediate vicinity of the Project and the implementation of spill response plans, the residual adverse effects to Marine Species and Habitats are predicted to be not significant.

Migratory Birds

Changes to ambient noise (Section 7.2) and light (Section 7.3) may affect migratory birds through driving them out of the area and/or other effects on their behaviour. These effects in turn may affect change the risk of bird mortality or injury and result in changes to habitat quality and use.

Mortality of a single individual of a migratory or non-migratory Species at Risk or a large number of migratory birds could be considered a significant adverse environmental effect. Effects on critical habitat of a migratory bird SAR which cause breeding failure or abandonment of nesting may also be considered significant, even if the effects are temporary. This would include abandonment or nesting failure of a migratory bird SAR or at a seabird/waterbird colony due to an accidental event or the response to an accidental event associated with the Project.

A variety of generic and site mitigation and environmental protection measures are described to minimize or eliminate Project-related effects to migratory birds; please see Sections 7.2, 7.3, 7.9.4 and 7.12. Following the implementation of these mitigation measures over the course of the Project, residual adverse effects are predicted to be not significant.

7.18.2 Power and Duty by Federal Authority

Should the Black Point Quarry Project require a federal authority to exercise a power or perform a duty (e.g., grant a permit) CEAA, 2012 requires that the Proponent take into account:

(a) a change that may be caused to the environment (other than those described in the previous section) and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function; and

(b) an effect, other than those already described regarding aboriginal peoples, of any change referred to in paragraph (a) on

(i) health and socio-economic conditions,

(ii) physical and cultural heritage, or

(iii) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.

The marine terminal component of the Project is expected to result in "serious harm to fish" (i.e., the death of fish or permanent alteration to, or destruction of, fish habitat) for species that are

part of or support a commercial, recreational or Aboriginal fishery. Under these circumstances, the *Fisheries Act* authorisation will be required to undertake the Project. Changes to fish and fish habitat and proposed mitigation measures are described in the preceding Section. As noted, with the implementation of these mitigation measures no significant residual environmental effects are expected.

The potential effects on Aboriginal peoples as required by section 5(2)(b) of CEAA, 2012 are summarized in Section 7.18.4 below.

7.18.3 Changes Expected on Federal or Transboundary Lands

The marine components of the Project, especially aggregate shipping, have the potential to result in changes to the environment on federal submerged lands and federal waters. Shipping routes will enter Canada's territorial sea and internal waters (Chedabucto Bay), both of which constitute federal lands as defined under section 2(1) of CEAA, 2012. Changes to Marine Species and Habitat VC will occur on federal submerged lands and in federal waters; these changes are described in Section 7.11 above. Apart from these changes, the Project may also result in changes to Commercial Fisheries and Aboriginal Land and Resource Use (Mi'kmaq fisheries). These changes are presented in more detail in Sections 7.15 (Commercial Fisheries) and 7.17 (Aboriginal Land and Resource Use).

The primary potential effect to the Commercial Fishery on submerged federal lands/federal waters is a potential change in availability of fisheries resources. This change would occur primarily at the marine terminal but may on occasion extend into Chedabucto Bay if Project-related shipping affects shrimp fishing activities in deeper waters. Although the shipping route has been selected to avoid preferred shrimping grounds, it is conceivable that shrimp fishers may occasionally be displaced from portions of these grounds should weather conditions or pilot advices necessitate an alternative shipping route. Given the small extent of the potentially affected area and the temporary nature of such events, the potential for significant adverse residual environmental effects is low.

In the case of an accidental event leading to a fuel spill in the marine environment, a potential significant adverse effect may experience by the Commercial Fisheries VC. However, the application of spill response efforts, an Emergency Response Plan (which includes spill dispersion modelling), and emergency preparedness training on ship and at the Project site, significant residual effects on Commercial Fisheries are not likely to occur.

As noted in Section 7.17 (Mi'kmaq Land and Resource Use) limited Mi'kmaq communal commercial fisheries are present at and near the Black Point Project site. A single shrimp license is fished in the southern portion of Chedabucto Bay; the Mi'kmaq-allocated traps are distributed among several non-Mi'kmaq fishermen. Given the presence of communal commercial fisheries in the area, there is a potential for a change to Aboriginal Land and Resource Use. The same mitigation measures described for Commercial Fisheries are applicable to this VC. Given the implementation of the mitigation measures described above for Commercial Fisheries, the residual effects on this VC, including in the event of an accidental fuel spill in the marine environment, are expected to be not significant.

7.18.4 Effects of Changes to the Environment

This section summarizes the effects of changes to the environment that may be caused to those components listed in section 5(1)(c) and 5(2)(b) of CEAA, 2012. The information presented in this section is summarized from the environment effects assessment presented throughout Section 7.0 of the EIS and include:

1. Effects of changes to the environment on Aboriginal people (CEAA section 5(1)(c); and
2. Effects of changes to the environment that are directly linked or necessarily incidental to federal decisions (CEAA section 5(2)(b)).

Effects on Aboriginal People

As stipulated in section 5(1)(c) of CEAA, 2012, this section summarizes the effects of changes to the environment on Aboriginal people caused by the Project, namely:

- health and socio-economic conditions,
- physical and cultural heritage,
- the current use of lands and resources for traditional purposes, or
- any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.

Given the distance from the Project site to the nearest Mi'kmaq community (Paqtnekek First Nation located 66 km away from the site), potential Project-related effects such as changes to air quality and ambient noise are not likely to affect the health of Aboriginal people. An accidental fuel spill in the marine environment may negatively affect communal commercial or CRA fisheries however such impacted species would not be consumed and thus no health effects would be expected.

An MEKS was undertaken to characterise past and current traditional use of the Project site including the nearshore areas of Chedabucto Bay where the marine terminal will be constructed (Appendix K). To supplement this work, Mi'kmaq representatives from the neighboring Mi'kmaq communities were contacted to discuss ongoing fishing activity in the Project area. As noted in the MEKS (**Appendix K**), the site is not currently visited for resource harvesting and there are currently no FSC fisheries at the Project site. This is not to conclude that the Project site will not be visited in the future for FSC purposes. Under these circumstances, however, changes to the environment caused by the Project are not likely to affect physical and cultural heritage or the current use of lands and resources for traditional purposes.

Archeological investigations conducted during the course of this EIS concluded there is low potential for presence of Mi'kmaq artifacts or remains on the site. Given this, Project activities are not anticipated to result in any changes to the environment that would have an effect on Aboriginal physical and cultural heritage areas, sites, structures or other resources.

Effects Linked or Incidental to Federal Decisions

As stipulated in section 5(2) (b) of CEAA, 2012, this section summarizes the effects of changes to the environment “directly linked or necessarily incidental to a federal authority’s exercise of a power or performance of a duty or function” required to allow the Project to proceed, if any of the following are affected:

- health and socio-economic conditions,
- physical and cultural heritage, or
- any structure, site or thing that is of historical, archaeological, paleontological or architectural significance.

An Authorisation for serious harm to fish under section 35(2)(b) of the Fisheries Act will likely be required to permit the construction and operation of the marine terminal. A Navigation Act Approval will be required for marine terminal construction and may be required for watercourse crossings. The anticipated “change” or environmental effect is a potential change in habitat quality and use of the Marine Species and Habitat VC. The marine terminal is not expected to result in adverse effects to health, physical and cultural heritage, or any structure, site or thing that is of historical, archaeological, paleontological or architectural significance. In contrast, effects on socio-economic conditions may result from the terminal’s effect on the commercial fisheries through:

- Change in risk of fish injury or death; and
- Change in fish or other habitat quality and use;

Given that these potential changes to the environment are expected to be temporary and confined to the area around the marine terminal and to the designated shipping routes between the terminal and the main shipping lanes in Chedabucto Bay, the effects of these potential changes are not expected to alter the socio-economic conditions for commercial fishermen. Following implementation of the mitigation measures described in Sections 7.15 and 7.17 (including fisheries offset projects), residual environmental effects on Marine Species and Habitats and related residual environmental effects on socio-economic conditions related to Commercial Fisheries, are predicted to be not significant.

**Table 7.18-1:
Summary of Environmental Mitigation**

Subject Category	Change or Effect	Mitigation	Follow Up Programs and Commitments
Changes to components within federal jurisdiction	<u>Freshwater Fish Habitat</u> Change to flow and water quality in Reynolds Brook, assumed to support fish	<ul style="list-style-type: none"> • Creation of a 30 ha lake following Project cessation • Erosion and Sediment Control Plan • Stormwater Management Plan • Emergency Response and Spill Contingency Plan 	<ul style="list-style-type: none"> • Habitat assessment and determination of fish presence/absence in Reynolds Brook. • Flow and water quality monitoring in Reynolds Brook prior to and once the pit begins to affect flow to Reynolds Brook.
	<u>Marine Fish, Fish Habitat and Aquatic Species</u> Reduced habitat quality and habitat function due to altered water and sediment quality. Reduced habitat for fish that are part of or support commercial, recreational or Aboriginal fisheries resulting from construction of marine terminal. Fish mortality due to the use of explosives within the pit; behavioural changes to fish, crustaceans and other marine species due to noise and vibrations associated with explosives use. Mortality (marine plants, benthic and pelagic organisms, etc.) and/or the loss of benthic habitat due to the presence of the terminal and aggregate spills when the ships are loaded. Increased disturbance to marine flora and fauna and reduced habitat quality and function for marine species due to noise and vessel movement from increased ship traffic. Invasive species that may be introduced through the illegal discharge of ballast water.	<ul style="list-style-type: none"> • Environmental Management Plan • Application of appropriate timing windows for all in-water work. • Implementation of terrestrial erosion and sediment control measures. • Surface water monitoring to ensure that quality meets all regulatory standards prior to discharge • Install stockpiles, fuel and chemicals > 30 m from the coast. • Emergency Response and Spill Contingency Plan. • Control ballast water release via "Ballast Water Control and Management Regulations" and the requirements as per the International Convention for the control and Management of Ship's Ballast Water and Sediments. 	<ul style="list-style-type: none"> • Fisheries Offset Program and associated effectiveness monitoring. • Surface water monitoring program
	<u>Migratory Birds</u> Changes to ambient noise and ambient light conditions may affect migratory birds through driving them out of the area and/or other effects	<ul style="list-style-type: none"> • Noise: please see mitigation measures described in Section 7.2 (Noise and Vibration) and Table 10-1 (Proposed Mitigation and 	<ul style="list-style-type: none"> • Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues

	<p>on their behaviour.</p> <p>These effects in turn may affect change the risk of bird mortality or injury and result in changes to habitat quality and use.</p>	<p>Monitoring by VC).</p> <ul style="list-style-type: none"> • Light: please see mitigation measures described in Section 7.3 (Ambient Light) and Table 10-1 (Proposed Mitigation and Monitoring by VC). • Please see additional mitigation measures in Section 7.9 (Terrestrial Wildlife) and Section 7.12 (SAR and SOCC), which are also summarized in Table 10-1 (Proposed Mitigation and Monitoring by VC). 	<p>related to lighting can be identified.</p> <ul style="list-style-type: none"> • The Environmental Management Plan will include instructions on implementing the protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) for responding to avian strandings related to activities in the marine environment. • Nightly site inspections will reveal opportunities for light reduction
Changes to the environment on federal or transboundary lands	<p>Changes to federal submerged lands and in federal waters in the form of changes to Commercial Fisheries including Mi'kmaq Fisheries), Marine Species and Habitat and Marine Surface Waters. These changes may occur through construction and operation of the marine terminal, aggregate shipping, and/or accidental spills in the marine environment.</p>	<ul style="list-style-type: none"> • Environmental Management Plan • Application of appropriate timing windows for in-water work. • Erosion and Sediment Control Plan • Surface water monitoring to ensure that quality meets all regulatory standards prior to discharge. • Install stockpiles, fuel and chemical storage facilities > 30 m from the coast • Emergency Response and Spill Contingency Plan. • Control ballast water release via "<i>Ballast Water Control and Management Regulations</i>" and the requirements as per the International Convention for the control and Management of Ship's Ballast Water and Sediments. • The quarry site office will be manned 24 hrs/day so that fishermen can telephone to receive information regarding vessel arrival and departures. • The phone number can also be used to report loss or damage to gear caused by Project-related vessel traffic. 	<ul style="list-style-type: none"> • Fisheries Offset Program and associated monitoring for effectiveness. • Concussion and ground vibration monitoring during each blast to ensure limits established by DFO for the marine environment are respected. • Mi'kmaq resource harvesting activities will be reviewed with Mi'kmaq representatives at the Community Liaison Committee meetings.

		<ul style="list-style-type: none"> • Routine communication with potentially affected Mi'kmaq will occur through the CLC. • Any future potential Project impacts (environmental, social and economic) on these harvesting activities will be a matter of the formal and regular meetings with the Mi'kmaq community representatives.

The impact of construction in the marine environment during and after lobster fishing season will be minimized to the extent possible. The quarry site office will be manned 24 hrs/day so that fishermen can telephone to receive information regarding vessel arrival and departures. The phone number can also be used to report loss or damage to gear caused by Project-related vessel traffic. Routine communication with potentially affected Mi'kmaq will occur through the CLC. 	<ul style="list-style-type: none"> Monitoring of progress and implementation of MOU and any other agreements reached with other First Nation communities. Mi'kmaq resource harvesting activities will be reviewed with Mi'kmaq representatives at the Community Liaison Committee meetings. Monitoring terminal operations and fishing access in response to concerns expressed by local fishing community, as needed; Fisheries Offset Program; monitoring of the effectiveness of the marine Fisheries Offset Program for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met.

7.19 ACCIDENT AND MALFUNCTION SCENARIOS

The assessment of potential environmental effects resulting from accidents and malfunctions differs from the assessments completed for individual VCs. This assessment employs risk based approach that involves two steps:

1. Identification of hazards associated with the Project infrastructure and activities to be undertaken on-site or off-site. These potential hazards are identified based on past experience with quarries similar to the Black Point Project and with similar types of works and activities in general.
2. Identification of potential environmental effects or the anticipated consequences of the identified hazards by completing a qualitative risk assessment aimed at providing some perspective on the hazards and their consequences by rating the likelihood of the adverse environmental effects. This rating represents the overall assessment of significance for the potential adverse environmental effects of accidents and malfunctions.

Only those accidents and malfunctions that are considered to have both a measureable environmental effect and a high probability of occurring during the life of the Project are considered in this assessment. For these “credible” accidents and malfunctions, the environmental effects identified represent a reasonable worst case outcome. Highly unlikely or hypothetical events (i.e., failure of multiple design features, contingencies and back-up systems) are not assessed.

The key accidents and malfunctions that could potentially occur during site preparation, construction, operation and closure phase of the Project are described in the following sections. Mitigation measures and planning to prevent the occurrence of such events, and response procedures to be implemented in the event they do occur, will be developed as part of the Industrial Approval application process and operational protocols.

It is anticipated that additional potential hazards, design and operational safeguards, and the need for further contingencies and emergency response measures may be identified during the review of the draft EIS report as well as through the ongoing public and Mi'kmaq engagement activities.

Malfunctions and accidental events will be prevented and mitigated through a systematic approach to worker health and safety and environmental protection. Health and safety policies and plans will be required from contractors while onsite workers will receive appropriate training to prevent and mitigate workplace accidents and environmental incidents.

7.19.1 Hazard Identification

Virtually all of the Project works and activities described in Section 3.0 have some potential for accidents and malfunctions. Those hazards with the greatest potential to result in environmental effects are:

- **Structural Failures:** These include quarry pit slope failure, aggregate stockpile slope failure, processing plant/marine terminal infrastructure failure and sediment pond failure;
- **Accidents:** These include an explosives accident, marine spills, transportation accidents (including vehicle and marine collisions), hydrocarbon spills on land or in the water; and,

- **Other Malfunctions:** These include unspecified health and safety incidents, wildlife encounters and forest fires.

Table 7.19-1 summarizes these hazards in terms of the Project phases during which they are most likely to occur. A solid dot indicates that there is higher potential for environmental effects to occur, while a hollow dot indicates a lesser potential.

**Table 7.19-1:
Summary of Accidents and Malfunctions by Project Phase**

Risk Category	Project Works or Activities	Project Phases During which Accidents and Malfunctions Could Occur				
		Site Preparation	Construction	Operations	Closure	Post-Closure
Structural Failure	Quarry Pit Slope Failure	–	–	●	○	○
	Stockpile Slope Failure	–	○	●	○	–
	Processing Plant/Marine Terminal Failure	○	○	●	○	–
	Sediment Pond Failure	○	○	●	○	○
Accident	Terrestrial Spill	○	○	●	○	–
	Explosives	–	○	●	–	–
	Marine Spill	–	–	●	–	–
	Transportation Accidents	○	○	●	○	–
Other	Forest/Site Fires	●	●	○	○	–

Legend : ● Greatest potential for adverse environmental effects.
○ Lesser potential for adverse environmental effects.

7.19.2 Structural Failures

Quarry Pit Slope Failure

Two primary open pit slope failures are possible:

1. Failure of the bedrock faces caused by improper mine design and operational procedures (including groundwater controls); and
2. Failure of overburden slopes.

The open pit will be excavated through into bedrock to an ultimate depth of approximately 130 m below ground surface (30 m below sea level). The side slopes follow well understood and accepted engineering practices of benched surfaces to provide for slope stability and space for quarry truck access ramps and roads. The final as-built design of the open pit will be engineered and approved at the regulatory stage prior to construction.

As noted in Section 3.0 the quarry benches will generally be 15 meters in height. Safety benches will be established every two benches and will have a width of approximately 7.5 meters. The final slopes for the quarry will have face angles of 85 degrees with a maximum pit slope of 65 degrees. Working benches will have face angles of 70 to 75 degrees.

As described in Section 6.1.9, the granite rock to be quarried has a “high” excavation difficulty, a “high” resistance to weathering and provides a “good” foundation support. The rock is dense (150-200 pcf) and has a very high compressive strength (up to 19,000 psi) (Koloski *et al.* 1989). Therefore, any potential pit instabilities are likely to be structurally controlled (along major joints/discontinuities).

With respect to the overburden, overburden thickness in the vicinity of the pit is typically less than 3 m thick and does not pose a significant risk of failure.

Significance Assessment

A significance environment effect of rock face failure is one that results in worker injury or death.

Potential Environmental Effects

Improperly designed and operated open pits can pose a safety hazard to workers during construction and operation. Apart from the safety hazard, no apparent environmental effects, outside of or in addition to those that would eventually occur through pit development, are evident.

The maximum effects due to pit slope failure are likely to occur during the pit closure period (i.e., just after quarrying is completed and the pit is allowed to start filling). This is because groundwater inflow will continue to occur while day to day observation of the pit slope will be less frequent, since the quarry crew will no longer be operating in the pit.

Mitigation and Emergency Response

During the quarrying process, the open pit slopes will be continually inspected by company staff and monitored by qualified mining engineers who will observe conditions on a daily basis and can adjust the design of the pit wall to avoid unstable conditions.

Bedrock pit slope angles were established using standard of practice approaches and methodologies combined with the Proponents past experience quarrying granite for aggregate.

Specific emergency response procedures describing how to respond to a pit slope failure will be incorporated into the Emergency Response Plan.

Stockpile Slope Failure

Overburden and topsoil stockpiles will be formed into a screening berm along the southern property boundary as discussed in Section 3.0. The screening berm will have a maximum height of about 3 m and will be designed with slope angles that promote stability through the establishment of a vegetation cover.

Aggregate stockpile failure will be contained entirely within the coastal platform near the processing plant, since this entire area will be sloped to south during initial site preparation to help accumulate stormwater runoff needed for the aggregate washing.

Significance Assessment

A significance environment effect of overburden or aggregate slope failure is one that results in worker injury or death.

Potential Environmental Effects

Given the low maximum height and the rapid stabilization expected once the screening berm is colonized by vegetation, the risk of berm failure is minimal. The berm will be placed within the 30 m undeveloped buffer along the southern property boundary. In the event that slumping occurs, soil will be confined within the property boundary and no significant environmental effects will occur.

Given the confining effect that will result by sloping the coastal platform to south, aggregate stockpile failure will not result in any environmental impacts. However, aggregate stockpile failure may result in worker injury or death, as well as damage to conveyors and processing equipment.

Mitigation and Emergency Response

Aggregate stockpiles will be located greater than 30 m from the coast on sloped platform designed to contain stormwater drainage. Overburden stockpiles will be placed at the southern property boundary no nearer than 20 m from the nearest watercourse and will be compacted using loaders and dump trucks. If needed, the screening berm can be artificially vegetated to prevent erosion but this is not considered necessary at this time. As needed, perimeter ditches will be installed to manage water from the screening berm.

If stockpile failure were to occur, the first response will be to cease all work in the area and ensure worker safety. When the failure area is secured, and depending on the scale of the failure, stockpile slope would be re-contoured in place. Slumped material would be excavated and returned to the stockpile, and if required drainage ditches would be repaired. An investigation into the causes of the failure would be undertaken so that the conditions leading to failure could be avoided or mitigation in the future.

Sedimentation Pond Failure

Sedimentation Pond Failure is defined as the failure of the retention pond embankment resulting in the release of stored water used for aggregate washing. As noted, the laydown area containing stockpiled materials will be designed to contain and direct runoff to the settling ponds. Failure of the engineered ponds to contain runoff is highly unlikely since these low, large volume ponds will be excavated into the rock and bermed with crushed stone several tens of meters thick.

Significance Assessment

A significance environment effect of a sedimentation pond failure is one that results in an uncontrolled discharge on sediment laden water to the environment.

Potential Environmental Effects

Due to the sloping and configuration of the coastal platform, sedimentation pond failure would not result in the release of sediment laden runoff to the environment. The ponds and nearby platform and stockpile areas would simply flood, which would halt quarrying activities until the water could be pumped into the pit sump. This also applies to “failure” of the pit sumps: the sumps may overflow but all water would remain fully contained within the pit. The settling ponds and pit sump are designed to allow water transfer between them; each can act as emergency storage for the other. In the case of excessive water, both the ponds and the pit sump can overflow without discharge to the ocean.

Mitigation and Emergency Response

The sedimentation ponds have been engineered to accommodate the anticipated stormwater runoff expected at the Project. These ponds and erosion and sediment control measures installed elsewhere in the Project area will be regularly inspected and monitored, particularly during and after extreme precipitation events. Erosion and sediment control structures found to be damaged will be repaired immediately and any other remedial action will be taken as necessary. Fines storage will be confined to areas within the quarry pit so any control failures would not result in an off-site release of material.

In a pit flooding event, pit water would be pumped to the sedimentation ponds for clarification prior to discharge. If the sedimentation ponds were already full, the site manager would wait until the water clarified within the sump, sample the clarified water and if found to meet discharge requirements, pump the water to Chedabucto Bay. This would not interfere with quarrying activities, which could continue elsewhere in the quarry.

Retention pond-specific emergency response procedure will likely not be developed specifically for this component; however, inspection and emergency response procedures in reaction to erosion and sediment control failure will be described in the EMP.

Processing Plant/Marine Terminal Infrastructure Failure

Structural failure of processing plant components (crushers, screening, conveyors, supporting structures, etc.) or the shiploader at the marine terminal may occur over time as joints loosen or metal becomes worn, weakened or corroded.

Significance Assessment

A significance environment effect of a structural failure is one that results in worker injury or death. There is no risk of negative environmental effects associated with such failure. Even if failure of the shiploader arm were to lead to an aggregate spill in the marine environment, the crushed granite is already washed of its fine materials, chemically inert, and would be easily colonized by marine biota.

Potential Environmental Effects

There are no potential environmental effects, apart from worker health and safety considerations, associated with structural failure.

Mitigation and Emergency Response

Equipment wear and tear is expected over the life of the quarry, particularly in a coastal environment subject to salt spray and consequent corrosion. Given this, a regular inspection and maintenance program will be initiated as a matter of course so that worn or inefficient equipment can be replaced on a regularly scheduled maintenance rotation.

Emergency response procedures will primarily be those responses applicable to accidents and worker injury. These procedures will be contained within the Workplace Health and Safety Emergency Response Plan.

7.19.3 Accidents

Terrestrial Spills

Spills onto the land may occur during any phase of the Project. During site preparation and construction spills will be limited to those materials available onsite, which will include:

- Petroleum products consisting of gasoline and diesel fuel; and
- Oils and lubricants

The operations phase will include those materials listed above as well as limited volumes of waste oil, used glycol, spent parts washer fluids and other materials generated during equipment maintenance.

During decommissioning, the reservoirs used to store these materials will be dismantled so that only limited amounts of raw and waste liquids will be stored on site.

Releases may occur during fuelling or through breaks or leaks in hydraulic lines, and/or storage container failure. The amount of any potential spill is limited to the size of fuel tanks, storage tanks and equipment tanks.

Significance Assessment

A significance environment effect of a terrestrial spill is one that results in loss of any quantity fuel, oil or lubricant, or any other Project-related raw materials to the environment such that a measureable impairment of the terrestrial, freshwater or marine environment results. Such impairment may be defined by:

Groundwater: when groundwater discharge to surface water bodies no longer meets Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 1999 as updated).

Surface Freshwater and Marine Waters: if water quality no longer meets criteria listed in the CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, freshwater and marine (CCME 1999 as updated) and/or NSE's Table 3 Tier 1 Environmental Quality Standards for Surface Water. Table 3 provides criteria for a variety of potential contaminants in both fresh and marine surface waters. All criteria are for the protection of aquatic life.

Potential Environmental Effects

Small spills will have negligible environmental effects. In the event of a large spill or leak, soil, groundwater and surface water contamination may occur, although it is unlikely that a spill will adversely affect the quality of wildlife habitats since the working areas of this industrial site where a spill might occur will be largely devoid of vegetation. Fuel storage and equipment maintenance will occur in a dedicated area near the access road entrance to the coastal platform. This area located more than 60 m from the nearest surface watercourse and more than 100 m from the ocean.

A fire is also possible if precautions are not taken to prevent exposure to an ignition source near the spilled flammable material. A transient negative effect on air quality would also be possible due to the volatilization of the spilled material.

Mitigation and Emergency Response

Fuelling of land based equipment will need to be conducted onsite on a regular basis. Fuel will be stored in above ground storage containers as indicated in Section 3. All storage tanks will be either double walled self-contained tanks or single walled tanks with secondary containment. All petroleum storage containers 55 gallons (208 L) or larger will be stored within a contained area capable of holding 110% of the volume of the largest reservoir placed within it. The fuelling area will be erected on a reinforced concrete slab or lined containment area enclosed within side curbs and with a sloping floor to contain any spills and/or leaks that may occur during fuelling. These materials will be stored and handled in accordance with all relevant regulations. All staff will have a minimum level of awareness training related to the handling and storage of fuels, chemicals and wastes. In addition there will be strict re-fuelling protocols for heavy equipment that will minimize the risk of accidental spillage.

All Project equipment and vehicles will be maintained to ensure they meet safety standards and are in good operating condition. Regular pre-shift inspections and maintenance programs will ensure the continued reliability and integrity of such equipment.

All fuel, chemicals and wastes will be handled in a manner that minimizes or eliminates spillage and accidents. In the event of a spill or leak during fuelling activities, maintenance, or general equipment operation, immediate action will be taken to stop and contain the spilled material. In addition, a complete Spill Contingency Plan will be developed and approved by regulatory agencies prior to construction. Staff will receive extensive training in responding to spill events and Spill Contingency Plans will be posted for viewing by all staff. There will also be spill training drills to ensure that operations personnel are trained and able to handle unforeseen events.

Hazardous materials will be handled and stored in accordance with provincial hazardous materials regulations and regulations enacted under the Canadian Environmental Protection Act, as applicable. Hazardous materials will be transported for off-site disposal using a licensed hazardous waste transport company. Employees will be trained on proper handling and management practices for these materials.

Terrestrial spills would be localized and easily cleaned up using standard equipment such as absorbent pads and spill responses procedures. All contaminated material will be collected and stored in an appropriate manner so as to not result in a re-release to the environment until such a time as it will be transported to an approved treatment / disposal facility.

All spills will be reported to the 24-hour environmental emergencies reporting system (1-800-565-1633) in accordance with the Emergency Spill Regulations under the Nova Scotia Environment Act.

Vessel Accidents / Collisions

During construction and operation of the marine terminal, considerable vessel activity by multiple ships and boats may occur for limited periods of time around the site. Given this, there is potential for Project related vessel collisions, primarily between aggregate transport ships and either tugs, pilot vessels or nearby recreational or fishing vessels. Other accident types may include collisions with the terminal during bad weather or due to pilot error and grounding of the vessel on submerged rocks. Navigational error, malfunctioning of navigation equipment, engine malfunction and poor weather conditions may all contribute to these accidents.

Significance Assessment

A significance environment effect of a vessel accident or collision is one that results in worker injury or death or loss of any quantity fuel, oil or lubricant to the marine environment such that water quality no longer meets criteria listed in the CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, marine (CCME 1999 as updated) and/or NSE's Table 3 Tier 1 Environmental Quality Standards for Surface Water (marine).

Potential Environmental Effects

In the event of a vessel tank rupture following an accident at sea, up to 2500 to 3000 metric tonnes of marine diesel oil fuel could be discharged to the marine environment. Fuel containment would be achieved using booms, absorbents and dispersants deployed from stock

on board and/or maintained at the quarry site near the marine terminal. In warm weather, the fuel can be expected to degrade and evaporate over a relatively short time, but this process would be slowed in the winter until the following summer.

Mitigation and Emergency Response

The management of marine traffic in Chedabucto Bay is under the responsibility of the Canadian Coast Guard. It is mandatory that all large vessel traffic report to the Canadian Coast Guard at specified points and that vessels approaching or leaving the marine terminal allow the boarding of a trained and experienced pilot.

Aggregate transport vessels will employ double hulled fuel reservoirs to reduce the risk that a collision will pierce the tank and release fuel. The potential for collisions will be minimized through controlling vessel speed; scheduling and coordinating activities with other marine users, Transport Canada and the Canadian Coast Guard; and posting Notices to mariners as needed. The marine terminal will contain navigational aids and anti-collision radar will provide early warning of a potential collision hazard. In addition, a Mooring Plan that identifies and establishes operating limits for all marine terminal activities (berthing, mooring, and aggregate loading, etc.) under severe atmospheric and/or oceanographic conditions will be employed to minimize collision risks. Emergency response in the event of a vessel collision is coordinated by the Canadian Coast Guard with support from local land based emergency responders as needed. The Coast Guard will be naturally aware of the timing and type of activity associated with the marine terminal operation and will be informed of the construction schedule before work begins. The Proponent's Emergency Response Plan will contain a section regarding response to incidents at sea, however the ship's Master is ultimately responsible for the safe operation and emergency response in case of accident.

Explosives Accident

An explosives accident would be limited to the construction and operational phases of the Project. No explosives will be stored or manufactured on site. The Proponent will contract the explosives component of this project to a licensed blasting contractor. Accidents may include premature blasts or accidental detonation of blasting components. A review of accident data indicates that "flyrock" and lack of blast area security were the primary causes of blasting related injuries in surface mining. Fatal injuries due to lack of blast area security were attributed to: failure to clear blast area; failure to follow instructions; inadequate guarding; inadequate blasting shelter; and unsafe location (Bajpayee et al, 1999).

Significance Assessment

A significance environment effect of an explosives accident is one that results in worker injury or death or environmental impairment. Such impairment is defined as

Groundwater: when groundwater discharge to surface waterbodies no longer meets Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 1999 as updated).

Surface Freshwater and Marine Waters: if water quality no longer meets criteria listed in the CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, freshwater and marine (CCME 1999 as updated) and/or NSE's Table 3 Tier 1 Environmental Quality Standards

for Surface Water. Table 3 provides criteria for a variety of potential contaminants in both fresh and marine surface waters. All criteria are for the protection of aquatic life.

Potential Environmental Effects

A spill of fuel oil and/or ammonium nitrate (the ANFO explosives mixture), or the emulsion itself has the potential to contaminate local ground and surface water. Given the use of explosives exclusively within the pit area, any release would likely be to water collected in the pit sump. This provides the opportunity to treat and test the water prior to discharge, minimizing the risk of environmental effects. A spill from a truck in transit to the pit (i.e., on the access road) has a greater possibility of reaching soil and surface watercourses.

Mitigation and Emergency Response Procedures

Preventive measures aimed at reducing the effects of blast accidents include: ensuring that all personnel have evacuated the blast area during shot firing; using adequate blasting shelters for employees whose presence is required in the blast area; controlling and monitoring all entrances to the blast area; ensuring that the blast is properly designed, drilled, and loaded; and emphasizing education and training to enhance skill levels for implementation of engineering control techniques.

Other measures that will be taken to minimize the risk of an incident involving explosives include:

- No explosive material will be stored onsite;
- All blasting activities will be conducted an experienced and trained, licensed contractor;
- The blasting operator will be responsible for blast designs and methods in accordance with the Blasting Safety Regulations made pursuant to the Nova Scotia Occupational Health and Safety Act, the Guidelines for the Use of Explosives in or Near Canadian Fisheries Waters (Wright and Hopky 1998), and in accordance with the Nova Scotia Pit and Quarry Guidelines (NSEL 1999).
- The blast area will be properly secured and notifications issued to workers.
- The Proponent's staff will receive spill response training and will be familiar with the provisions of the site-specific Emergency Response Plan. This plan will address spill response on the quarry property.
- The licensed blasting contractor will maintain his own emergency response plan and staff training records. The Proponent will have the opportunity to review this plan and integrate any explosives-specific measures into the Black Point Emergency Response Plan.

Should an explosive component spill occur, the spill will be managed as per instructions within the Emergency Response Plan and under the direction of the blasting contractor. A spill from a truck on the access road or elsewhere within the property would be managed by the Proponent's staff as any other fuel spill.

Marine Spills

A spill of hydrocarbons in the marine environment could occur during the construction, operation and decommissioning phases of the marine terminal. The potential sources of a fuel spill at or near the marine terminal include vessel collisions with the terminal or with other vessels. No fuel

will be stored at the terminal and no vessel refuelling will occur at the Black Point Quarry. No vessel maintenance will occur at the terminal.

Significance Assessment

A significance environment effect of a marine spill is one that results in contamination such that marine water quality no longer meets criteria listed in the CCME Canadian Water Quality Guidelines for the Protection of Aquatic Life, marine (CCME 1999 as updated) and/or NSE's Table 3 Tier 1 Environmental Quality Standards for Surface Water (marine).

Potential Environmental Effects

As noted above under vessel collisions, release of hydrocarbons to the marine environment has the potential to impact aquatic life (fish, marine mammals and birds), and their respective habitats. A significant spill would also affect commercial fishing interests.

The impacts of such an event may include diesel fuel deposited onto the shoreline and an oil slick expanding to cover an area beyond the immediate spill location. Over the short term (i.e., from the spill to approximately 10 days) impact of such a spill might include fish kills, coating of the fur and feathers of marine mammals and birds, and loss of lobster and other marine species in the immediate area of the spill as well as in areas where the slick migrates before being contained. Over the longer term (i.e., one month and beyond) residual impacts following cleanup of the spill might include impairment of fisheries productivity. Certain mobile species could relocate to other areas; impacts to breeding areas could create lead to decreases in fisheries productivity over time.

Mitigation and Emergency Response Procedures

As noted, vessels will not be refuelled at the marine terminal. All shipping and associated activities (refuelling, waste management, etc.) will be contracted by the Proponent to a third party. This allows the Proponent to select reputable shipping firms with a demonstrated history of safety and operational integrity. The use of experienced, well trained and trustworthy shipping crews, tugs and pilots helps to minimize the potential for collisions leading to spills, and illegal ballast water discharge.

The Project will mitigate marine spill risk by ensuring that ship docking at the terminal is tug and pilot assisted as needed and required by law, the terminal and mooring structures are properly constructed and well lit, and also by having a written agreement with a certified spill response contractor to provide response services in the event of a spill. Other mitigating factors include continual redesign of vessels to make them less susceptible to collision damage. This will reduce this risk over the life of the Project. Finally, an Emergency Spill Response Plan that contains predictive oil spill modelling will be prepared and emergency response training will be employed at the site. Advance planning including mock simulations of spill events and maintenance of spill response equipment at the site to ensure rapid deployment will reduce the response time required to contain the spill which is a key part of reducing the damage to the environment.

Transportation Accident

Vehicular collisions may occur during any phase of the Project. Mobile equipment at the quarry will include excavators, loaders, off-road trucks, bulldozers, water trucks, cranes, drill rigs and service vehicles. Most vehicle traffic is confined to the pit where rock is loaded and transported to the primary crusher. Once the quarried rock has been deposited in the primary crusher, subsequent aggregate transport occurs largely via conveyor.

Significance Assessment

A significance environment effect of a terrestrial vehicular accident is one that results in worker injury or death.

Potential Environmental Effects

A vehicle collision or accident has very little potential to lead to significant environmental damage. Fuel spills from vehicle accidents within the pit will be confined to the pit. Spills from accidents on the access road may attain roadside ditches but the volume of fuel spilled is expected to be minimal. The most significant risk is that posed to worker health and safety.

Mitigation and Emergency Response Procedures

The Proponent has considerable experience in managing the many vehicles that operate within an active quarry. Accident mitigation begins with adequate worker training, and by employing experienced workers to the extent possible. Other controls include ensure access and haul roads are sufficiently wide to allow safe passage of two vehicles side by side, clearing vegetation to ensure adequate line-of-sight around corners and at road junctions, posting and enforcing speed limits within the quarry, the use of in-vehicle radios linked to a central dispatch, and regular maintenance of brakes, tires and other vehicle components.

Emergency response in the event of a vehicle collision or accident would follow procedures outlined in the site-specific Emergency Response Plan.

Ballast Discharge

Under the *Ballast Water Control and Management Regulations*, all ships entering Canadian waters must exchange ballast water outside of the Exclusive Economic Zone (200 nautical miles from shore), treat their ballast water, discharge their ballast water to a reception facility, or retain their ballast water on board ship. This reduces the risk of introducing invasive species to Canadian waters and prevents unauthorised discharge of bilge water and non-compliant ballast water. Ships that fail to do this and discharge untreated ballast water within the Exclusive Economic Zone are committing a criminal act.

Significance Assessment

A significance environment effect of an illegal ballast water discharge is one that results in the release and establishment of a non-native species to Canadian waters.

Potential Environmental Effects

As described in Section 6.11, ballast water taken aboard ships in foreign ports may contain organisms that are not native to Nova Scotia, and which could cause harm to local ecosystems. In Nova Scotia these organisms include green crab, several species of sea squirts (tunicates), Dead Man's Fingers (*Codium fragile*) and *Membranipora membranacea*.

Mitigation and Emergency Response Procedures

In addition the provisions of the *Ballast Water Control and Management Regulations* described above, an international convention regarding ballast water has been adopted by the International Maritime Organization (IMO); ratification is expected in 2015. Under IMO's International Convention for the Control and Management of Ships' Ballast Water and Sediments, all vessels will be required to report and treat ballast water using an IMO approved method. This convention will further limit the opportunities for illegal ballast dumping.

7.19.4 Other

Forest Fire

A lightning strike or human carelessness may cause a forest fire at or near the site, requiring emergency response from site staff. An accidental fire at the Project site may also occur but this is considered unlikely due to the lack of flammable materials within the quarry and processing plant. Vehicle fires, while uncommon, may also occur. Due to the lack of vegetation, it is unlikely that a vehicle or other on-site fire could cause a forest fire that might spread elsewhere.

Significance Assessment

A significance environment effect of a forest fire at the Project site is one that results in worker injury or death or a fuel spill, which in turn results in the effects listed above.

Potential Environmental Effects

The immediate concern with respect to a forest or vehicular fire is for human health and safety; additional concerns include habitat loss, direct mortality to wildlife, and loss or damage of property. The emissions from a fire would likely consist mainly of smoke (particulate matter) and CO₂, but could also include CO, NO_x, SO₂, and other products of incomplete combustion. A large fire could create air contaminant levels greater than the ambient air quality standard over distances of several kilometres; however, the likelihood of such cases is considered low and the event would be of short duration.

Mitigation by Design and Operational Safeguards

Fire detection systems will be provided at appropriate locations such as the administrative office and fuel dispensing/maintenance shop. All buildings will meet National Building Code of Canada construction standards and will be equipped with appropriate fire suppression systems such fire extinguishers or sprinklers as needed.

The fuel storage facilities will be designed to meet the National Fire Code of Canada requirements and will meet the provincial storage regulations for these facilities.

All Worker Health and Safety requirements regarding fire preparedness will be met, including ensuring that a suitable number of workers are trained in firefighting and tested for proficiency at least once per year. All plant personnel will be trained on:

- Fire hazards;
- Fire prevention; and
- Firefighting roles, responsibilities and requirements for their respective positions.

In addition, all personnel will be provided with orientation and training, including conducting regular fire drills and evacuation.

The site-specific Emergency Response Plan or portions thereof will be distributed to the Queensport and Canso Fire Departments. Representatives of these Departments will be invited to meet with the Black Point Safety Supervisor or equivalent in order to view the site layout and infrastructure, review access and evacuation routes and understand the activities undertaken at the site.

Contingency and Emergency Response Procedures

Emergency response procedures will be developed as part of the Emergency Response Plan. This plan will address how to respond to a fire on the property. Evacuation of personnel from the area will be the highest priority. Meeting places for site workers will be established and headcounts taken to account for all personnel. In the unlikely event of a large fire, local emergency response and firefighting capability will be called to respond to reduce the severity and extent of damage and to protect the safety of workers. The fire department will be notified of the hazardous materials on the site and health concerns related to the chemicals including required personal protective equipment.

7.19.5 Risk Assessment

Each potential accident and malfunction discussed above was assessed according to likelihood of the event and given a risk rating from “negligible” to “high”. Environmental effects are assigned a magnitude rating from “low” to “extreme”. The combination of the likelihood of an event and the magnitude of its environmental effects is determined by plotting these ratings on the matrix shown on **Figure 7.19-1**. As shown in this matrix, increased risk is associated with accidents and malfunctions having a greater *likelihood* of occurrence and greater *magnitude* of effects.

Figure 7.19-1:
Risk Rating Matrix

The magnitude rating not only considers the mitigation, operational safeguards and emergency response available to minimize environmental effects, but also the cost of remediation (as a measure of severity). The magnitude ratings are defined as follows:

- **Low:** No long term effects, readily remediated with a cost in the \$10,000's;
- **Moderate:** Limited or no long term effects, remediated for costs in the \$100,000's;
- **High:** Moderate long term effects expected, remediated for costs in the \$ millions;
- **Very high:** Significant long term effects expected, costly remediation in the \$10s millions; and
- **Extreme:** Highly significant long term effects likely, remediation cost in the \$100s millions.

The risk ratings (likelihood) are defined as follows:

- **Negligible:** Not likely to occur (less than a 1 in 10,000 probability per year - 1/10,000 events per year);
- **Very Low:** Unlikely to occur (less than a 1 in 1,000 probability per year);

- **Low:** Possibly could happen (less than a 1 in 100 probability per year);
- **Moderate:** May happen (less than a 10% probability per year); and
- **High:** Can happen over the life of the mine (greater than a 10% probability per year).

Accidents and malfunctions with an overall combined rating of greater than or equal to 4 not are considered to be significant events or consequences. An overall combined rating of 3 requires that the accident or malfunction be considered further in during the project's detailed design phase. An overall combined rating of less than or equal to 2 would be considered significant.

Results of this qualitative analysis are provided in 7.18-2. The results indicate that all accidents and malfunctions described above have ratings ranging from 5 to 8. These events and their environmental effects are therefore considered not significant.

**Table 7.19-2:
Accidents and Malfunctions affected VECs**

Malfunction/Accident	Key VCs Potentially Effected	Risk Rating	Magnitude Rating	Overall Rating 1 = Maximum 9 = Minimum
Quarry Pit Slope Failure	Human Health and Safety	Negligible	High	7
Stockpile Slope Failure	Human Health and Safety Surface Water Resources Terrestrial Habitat and Vegetation	Negligible	Moderate	8
Sedimentation Pond Failure	Marine and Surface Water Resources Terrestrial Habitat and Vegetation Marine Species and Habitat Species at Risk	Very Low	Low	8
Marine Terminal Infrastructure Failure	Marine and Surface Water Resources Marine Species and Habitat Species at Risk	Very Low	Moderate	7
Processing Plant Infrastructure Failure	Marine and Surface Water Resources Marine Species and Habitat Species at Risk	Very Low	Moderate	7

Malfunction/Accident	Key VCs Potentially Effected	Risk Rating	Magnitude Rating	Overall Rating 1 = Maximum 9 = Minimum
	Marine and Surface Water Resources Terrestrial Habitat and Vegetation Terrestrial Wildlife Marine Species and Habitat Species at Risk			
Marine Spill	Human Health and Safety Marine and Surface Water Resources Marine Species and Habitat Species at Risk Local Economy Commercial Fisheries	Very Low	Very High	6
Illegal Ballast Discharge	Marine and Surface Water Resources Marine Species and Habitat Species at Risk Local Economy Commercial Fisheries	Low	High	5
Transportation Accident	Human Health and Safety Terrestrial Habitat and Vegetation Terrestrial Wildlife	Low	Moderate	8
Forest / Site Fire	Human Health and Safety Air Quality Terrestrial Habitat and Vegetation Terrestrial Wildlife Tourism and Recreation Aboriginal Land and Resources Use	Negligible	High	7

7.19.6 Conclusion

In the table above, the incidents having greatest likelihood of occurring, combined with the potential of doing the greatest harm, are given the lowest number. Accidents or malfunctions causing spills in the marine environment are ranked as the most risky compared to other incidents that may occur on site. Even so, the risk of a marine spill is not ranked as significant.

8.0 EFFECTS OF THE ENVIRONMENT ON THE PROJECT

Although environmental assessments typically focus on project-related impacts to the surrounding environment, assessment must also consider the effects of the environment on the project. This is particularly important given that climate change scenarios predict larger magnitude and more frequent extreme weather events, which in turn may negatively impact the Black Point Quarry Project operations.

The natural environment has the potential to adversely interact with the Project through meteorological, climatological and seismological events. These events may include:

- Drought or extreme precipitation events leading to flooding;
- Extreme (high/low) temperatures;
- Rapid or increasing number of freeze/thaw events;
- Lightning strikes;
- Severe wind storms including hurricanes;
- Extreme marine conditions (high waves plus extreme winds);
- Ice storms and hail events;
- Late season sea ice; and
- Earthquakes.

Project infrastructure will be designed to accommodate the conditions imposed by the natural environment and to accommodate, to the extent possible, expected effects of the climate on the Project. Project activities will include emergency preparedness to ensure rapid, organized response in the event of a severe climate episode.

The sections below describe how these events may impact Project infrastructure and activities and how these effects will be mitigated or managed to ensure worker safety, minimize disruptions to production and limit any environmental repercussions.

8.1 Potential Effects of Drought or Flooding

Flood and drought conditions may occur from time to time during the 50-year life of the Project. These events can be accommodated in the Project design as described in Section 6.2 and in the tables below.

The historical mean annual total precipitation for Guysborough is 1425 mm (NS 2014). Although extreme precipitation events may occur in any month of the year, rainfall in the Project area is generally highest during fall, both on a monthly basis and on a storm-by-storm basis. Snow and freezing precipitation can occur between October and May, with the largest amounts falling between December and March (Table 6.3-2).

The potential effects from drought and flooding on the Project and corresponding mitigation measures are summarized in Table 8-1.

Table 8-1: Potential Effects from Flooding or Drought on the Project

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
Drought Conditions	<ul style="list-style-type: none"> Increased dust on site; increased potential for off-site dust transport. Reduced availability of wash water for quarry operations. Reduced availability of on-site potable groundwater 	<ul style="list-style-type: none"> Develop a Water Management Plan that describes pre-determined measures to accumulate, conserve, and manage available water. With the prior approval of NSE, substitute chemical dust suppressants for water and apply to the access roads. Supplement on-site water with bottled water. 	<ul style="list-style-type: none"> Monitor water levels of the retention ponds. 	<ul style="list-style-type: none"> Neutralize and utilize water from onsite freshwater bodies If necessary obtain water supply from off-site
				<ul style="list-style-type: none"> Add or heighten berms around ponds as needed. Enlarge & deepen culverts; raise roads and other infrastructure above flood levels. Add a contingency factor when designing infrastructure to account for climate change
Flooding	<ul style="list-style-type: none"> Flooding of the pit Overflow of the onsite ponds. Flooding of culverts and roads resulting in road washout. 	<ul style="list-style-type: none"> Design facilities to handle excess water in extreme weather events. Schedule construction of surface water management infrastructure before the start of large excavation and earth works Reduce quarry activities and secure vulnerable mining equipment if pit becomes flooded Onsite ponds and sump systems have been sized to accommodate large storm events (i.e., 100-year 24-hour flood event). 	<ul style="list-style-type: none"> Routinely monitor weather forecasts and water levels in the ponds to assure they continually meet prescribed operating guidelines. Inspect damage from flooding on infrastructure such as roads, spillways and culverts, and repair as necessary. 	

8.2 Potential Effects of Extreme Temperatures

Air temperatures vary seasonally, and are highest in July when daily extremes can vary from 21.5° C to 13.1° C (Section 6.3). Short term summer extremes can vary from 30.8° C (May) to 33.3° C (June). The minimum average daily temperature occurs in February (-5.1° C) with extremes ranging from -8.6° C to -1.5° C. Short term extremes in the winter months can vary from -18.4° C (March) to -25.6° C (February). The Project's design and operational procedures can easily accommodate these temperature ranges, which are not considered unusually excessive by the Project team.

In Guysborough County, freeze-thaw cycles predominately occur in the winter months (40.6), with slightly less in the spring (33.2) and a few in the fall (8.7) (NS 2014). These cycles have the potential to damage roads and affect the stability and alignment of Project infrastructure.

The potential effects from extreme heat and cold temperatures on the Project and corresponding mitigation measures are summarized in Table 8-2.

Table 8-2: Potential Effects of Extreme Temperatures

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
High Temperatures	<ul style="list-style-type: none"> Hazard to worker health and safety. Heat damage to mechanical equipment. 	<ul style="list-style-type: none"> Implement an Occupational Health and Safety Management Plan to ensure worker safety. Staff will be trained in accordance with operating procedures and Management Plans. 	<ul style="list-style-type: none"> Inspect mechanical equipment for damage after extreme temperatures 	<ul style="list-style-type: none"> Upgrade mechanical equipment and worker safety equipment to allow for work in high temperatures.
Low Temperatures	<ul style="list-style-type: none"> Hazard to worker health and safety. Mechanical equipment problems 	<ul style="list-style-type: none"> Implement an Occupational Health and Safety Management Plan to ensure worker safety. 	<ul style="list-style-type: none"> Monitor weather conditions. Inspect equipment for stress and cold cracks; Inspect work areas for ice buildup, especially near the wash plant 	<ul style="list-style-type: none"> Maintain stockpile of vulnerable parts Replace damaged parts as soon as possible; refrain from using the equipment Maintain stockpiles of salt Upgrade mechanical equipment and worker safety equipment to allow for low temperatures work.
Freeze/thaw conditions	<ul style="list-style-type: none"> Development of pot holes and/or roads breaking apart making it a hazard to driving. Ice blockage of flow conveyance in ditches. Land access to marine terminal may temporarily be difficult due to thawing ground. Freezing of exposed piping and equipment that carry water (wash plant, dust suppression system, water conveyance and pumping equipment) 	<ul style="list-style-type: none"> Monitor roads for damage and repair before they get too hazardous Routinely inspect and maintain haul and access roads; repair as necessary. Incorporate awareness of the risks of thaws and sudden freezes in Occupational Health and Safety Management Plan to ensure worker safety and effective Project operations. Maintain access roads with quarry equipment to all critical operating and monitoring locations throughout the Project area. Implement freeze protection measures on equipment and pipes containing water 	<ul style="list-style-type: none"> Inspect damage to roadways and other infrastructure after major freeze/thaw events. Inspect work areas for ice buildup, especially near the wash plant. Inspect equipment for positional shifts due to frost heave Inspect equipment to ensure freeze protection measures are employed 	<ul style="list-style-type: none"> If necessary, reconstruct access road to provide improved performance during thaws. If necessary, heat trace or otherwise protect from freezing and above-ground water conveyance piping, equipment and systems. Refrain from using misaligned equipment

8.3 Potential Effects from Storms

The Atlantic coast of Nova Scotia and the south coast of Newfoundland experience more storms over the course of one year than any other region in Canada (EC 2006). These storms bring high winds along the coast, heavy precipitation, storm surges exceeding 1.0 m, freezing rain, and peak waves nearing 14 meters in height (EC 2006). The winds that affect the coast and mainland Nova Scotia can exceed 150 km/h, and may result in extreme wind chills during the winter (Section 6.3.)

The potential effects from storm events on the Project and corresponding mitigation measures are summarized in Table 8-3.

Thunderstorms are not common in the Project area. Burrows and Kochtubajda (2010) note that lightning activity is highly influenced by length of season, proximity to cold water bodies and elevation. In Nova Scotia winter lightning is common as Arctic air masses pass over warmer water. Based on data from 1999 to 2009, Burrows and Kochtubajda (2010) report that cloud to ground lightning occurs on average between five and ten times per year over much of Nova Scotia.

Table 8-3: Potential Effects from Storms

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
• Rain Storms	<ul style="list-style-type: none"> • Hazard to worker safety from potential flooding. • Dangerous driving conditions due to reduced visibility and washed out roads. • Project area flooding. 	<ul style="list-style-type: none"> • Incorporate flooding awareness and responses/procedures in the Occupational Health and Safety Management Plan to ensure worker safety. • Include stormwater management in the Environmental Management Plan. • If necessary, curtail quarry activities and secure vulnerable quarry facilities during flooding • Design pit slopes to provide for maximize slope stability during extreme storm events. 	<ul style="list-style-type: none"> • Monitor weather forecasts • Inspect damage from flooding on infrastructure such as roads, foundations, supports spillways and culverts and repair as necessary. • Monitor conditions during storms for the potential for forest fires due to damaged power lines. • Inspect pit walls for potential rock fall hazards. 	<ul style="list-style-type: none"> • Add or increase the height of berms around ponds. • Enlarge & deepen culverts and raise roads and other infrastructure above flood levels. • Remove loose rock from pit walls if deemed a hazard or secure area to control access.
• Ice Storm	<ul style="list-style-type: none"> • Hazard to workers safety due to slippery conditions. • Dangerous driving conditions due to reduced visibility and icy roads. • Chance of power outages due to ice on hydro lines or ice laden trees falling on the hydro lines. • Dangerous quarry conditions due to ice covered operational areas in the pit. 	<ul style="list-style-type: none"> • Provide a description of ice storm hazards and required responses/procedures in management plans to ensure worker safety including hazardous weather driving. • Incorporate emergency response procedures in the Project's Emergency Response plan. 	<ul style="list-style-type: none"> • Monitor weather forecasts • Inspect damage to power lines and trees surrounding power lines after an ice storm to prevent the possibility of power loss. • Inspect conditions of roads and infrastructure to ensure it is safe to continue work. 	<ul style="list-style-type: none"> • Keep trees trimmed along power lines • Have de-icing equipment on site for de-icing roads on site but also for de-icing quarry equipment. • Provide backup power sources in case of loss of power. • Reduce quarry operations in severe weather conditions.
• High Winds and Waves	<ul style="list-style-type: none"> • Delay in construction schedules • Impact to vessel berthing/loading procedures and schedules • High waves crashing into marina causing damage 	<ul style="list-style-type: none"> • Design marine terminal to withstand waves higher than normal and for extreme events • Schedule loading/unloading to accommodate anticipated storms 	<ul style="list-style-type: none"> • Inspect damage to power lines and trees surrounding power lines after an ice storm to prevent the possibility of power loss. • Monitor marine conditions to predict 	<ul style="list-style-type: none"> • Consider building a jetty to reduce the effects of the waves at the marine terminal • Contingency planning to include emergency evacuation and securing the quarry site

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
	<ul style="list-style-type: none"> • Chance of power outages due to trees falling on the hydro lines. 	<ul style="list-style-type: none"> • Install backup power sources in case of loss of power. 	when conditions may be favorable for higher waves	<ul style="list-style-type: none"> • Reduce or curtail quarry operations in severe weather conditions.
<ul style="list-style-type: none"> • Lightning Strikes 	<ul style="list-style-type: none"> • Damage to processing plant components • Worker injury or death • Power surges / power outages 	<ul style="list-style-type: none"> • Design plant equipment with grounding circuits (standard practice) • Comply with provisions in the National Electric Code. 	<ul style="list-style-type: none"> • Conduct annual continuity checks at the plant; • Monitor weather patterns. • Inspect equipment following severe storms and lightning strikes 	<ul style="list-style-type: none"> • Use warning siren to warn workers of severe weather events; • Cease operations in severe thunderstorm conditions; shut down processing plant; direct employees to a designated location

8.4 Potential Effects of Extreme Marine Conditions

Extreme weather events can develop more quickly on water than on land and are hazardous to the Project due to their sudden onset and intensity, potentially catching workers off guard. Storms can affect vessel berthing and loading, and increases the hazards to people working near water.

Freezing spray occurs when ocean spray generated from winds and heavy seas spreads over the ship and freezes on point of contact. The typical seasonal range for freezing spray occurs between November and April; however, it is highest in February (JWEL 2004). Land fast ice in Chedabucto Bay can persist into April, but the central Bay remains ice-free all year round.

A reduction of visibility due to fog can affect both land and sea operations of the Project. In Canso, 115 days of fog persisting for at least 1 hour were recorded in 2013 (EC 2006). Visibility of one-half nautical mile or less is common for the Chedabucto Bay area in all seasons.

The potential effects of extreme marine conditions on the Project and corresponding mitigation measures are summarized in Table 8-4.

Table 8-4: Potential Effects of Extreme Marine Conditions

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
Ice	<ul style="list-style-type: none"> • Delay in construction schedule • Change in shipping routes; shipping delays • Vessel and terminal icing due to freezing sea spray • Icing of the processing plant causing delays 	<ul style="list-style-type: none"> • De-icing procedures • Design heated plant or conveyor components if warranted, or add them later if justified 	<ul style="list-style-type: none"> • Inspection procedures for vessels and quarry machinery • Inspect work areas and equipment for ice buildup 	<ul style="list-style-type: none"> • Stockpile sand and salt abrasives before winter

8.5 Seismic Activity

Seismic activity in eastern Canada is associated with regional stress fields and sediment slumping at the edge of the continental shelf, rather than with plate boundaries as in western North America (Section 6.1). Although earthquakes of magnitude 4-5 have occasionally been reported in Nova Scotia, only two have been recorded in the western half of Nova Scotia; most occur offshore. Because of the low frequency of earthquakes and low magnitude of those that do occur, Guysborough County and by extension the Project site is considered to have very low level of seismic activity (NRCan 2014). Considering this, no adverse effects from earthquakes or tsunamis are expected on the Project. Moreover, the simply designed and robust Project infrastructure (conveyors, crushers, screening equipment, etc.) are not particularly vulnerable to earthquakes. Similarly, the durable rock faces of the quarry itself and the low buildings used as administrative offices are not vulnerable to seismic activity.

The potential effects from seismic on the Project and corresponding mitigation measures are summarized in Table 8-5.

Table 8-5: Potential Effects from Seismic Activity

Hazard	Potential Effects on the Project	Mitigation through Project Plans	Proposed Adaptive Management Measures	
			Inspection/ Surveillance	Contingency Actions
Earthquakes and Tsunamis	<ul style="list-style-type: none"> • Damage to processing plant and marine terminal infrastructure. • Rock slides in the pit • Potential worker safety impacts from above events. 	<ul style="list-style-type: none"> • All infrastructures will be built to the National Building Code of Canada. • Pit walls have been designed to perform stably under the design earthquake. 	<ul style="list-style-type: none"> • Inspect damage to roads, equipment, buildings, and other quarry infrastructure and repair as necessary. • Regularly monitor stability of pit walls and rock stockpiles 	<ul style="list-style-type: none"> • Upgrade building and road structures to withstand larger earthquakes. • Provide for backup power for critical infrastructure

8.6 Implications of Climate Change Trends

The interaction of the Project with weather events caused by climate change over time is assessed because the Project duration is long enough to experience climate change-induced extreme weather events. The increased annual precipitation predicted by climate change scenarios (10-20 % over the next 100 years [Richards and Daigle 2011]) can be accommodated in the design of the Project, but preparing for and adapting to regular, extreme weather events is more challenging.

Extreme weather, such as high winds and precipitation events, is predicted to increase in both frequency and intensity due to climate change (NS 2014). This could increase the risk from potential winter and spring flooding as well as flash flooding resulting from intense, single event rainfalls. As the frequency and intensity of storms increase, sea-level rise increases the baseline for flooding. Given this, storm surges for any given storm will reach further inland in the future than they would today (Wrightman 2012). With the predicted warmer springs and milder winters,

the frequency of ice storms such as the one experienced in Guysborough County in early 2014 will likely increase.

Air temperatures are expected to increase but extreme warming events are not anticipated to increase significantly (NS 2014). Most of the warming is expected to take place in the winter; however, the number of days with snow is expected to increase in the 2020s but then decline for the 2050s (NS 2014).

Over the duration of this Project, it is projected that the number of freeze-thaw events will remain relatively stable during the winter months, but these events are expected to decline in frequency during the spring and autumn (NS 2014).

Despite an increase in summer temperatures, the potential for forest fires is low because the Project site will be mostly cleared of trees. Forest fires are described in more detail in Section 7.18.

Both peak wind speeds and mean significant waves are predicted to increase in the future (NSE 2011).

Combining global sea-level rise projected for Canso Harbour to the year 2100 with crustal subsidence to the year 2100, Richards and Daigle (2011) calculate total sea level change at 0.45 m +/- 0.15 m to the year 2055 and 0.83 m +/- 0.36 m to the year 2085. They go on to estimate the storm surge for the 100-year return period is on the order of 0.8 m in the Canso-Chedabucto Bay area.

These total sea levels do not include the possibility of a rare historical event such as the Saxby Gale (1869), the Groundhog Day Storm (1976) or of a direct hit by a hurricane. From a design perspective it is prudent to consider the impacts of a plausible upper water level that would result from maximum estimated sea-level rise combined with crustal subsidence and the highest storm-surge factor previously recorded by a tide gauge. Taking these factors into account Richards and Daigle (2011) estimate that by 2085, the Extreme Total Sea Level will range from 3.42 m +/- 0.56 m (10 year return period) to 3.66 m +/- 0.56 m (100 year return period) at the Deming climate station in Guysborough County. These scenarios will be considered during the final design of the marine terminal and processing plant.

The Proponent has considered the risk of sea level rise and storm surge in the preliminary design of the operation. The surface elevation of the processing plant area will be increased to over 20 masl. This elevates the foundations of processing plant and loadout equipment above the level where future storm surges are expected to occur.

To prepare for extreme weather events, including sea level rise and anticipated storm surges over the lifetime of the Project, the Proponent will implement an Emergency Action Plan (EAP) prior to the start of construction. The EAP will describe the steps to be taken to prepare for the impacts of anticipated significant weather events such as hurricanes, wind storms, ice storms and blizzards. The measures that will be implemented will depend largely on the anticipated impacts. These measures may include for example:

- moving mobile equipment to a safe location and elevation;
- reinforcing the anchoring of stationary equipment;
- bringing down conveyors or securing them and filling belts that cannot be dropped by loading with stone;

- transferring fuel and other products stored in bulk to a secure location and/or anchoring tanks and closing and securing all connection valves and drain/fill lines;
- modifying or suspending marine operations to ensure that vessels are safely out of the area prior to storm impacts;
- de-energizing electrical equipment and disconnecting plant power; and
- draining water management systems including ponds, piping and ditches to ensure there is adequate free board to accept anticipated precipitation.

The Proponent will engage operations, environmental and safety, and risk management staff as well as local, Provincial and Canadian government agencies as appropriate in determining criteria used to activate the Emergency Action Plan and the specific measures taken in preparation for a storm.

Taking into account the mitigation included in the Project design and the adaptive management measures proposed above, Table 8-6 summarizes the key climate change trends and assesses their effects on the Project infrastructure and operations.

Table 8-6: Overall Implications of Climate Change Trends

Climate Factor Description	Climate Trend	Implication of Climate Change Trends			
		For Project Design	For Project Operations	For the Environmental Assessment	
Rain	Drought	Decreasing	<ul style="list-style-type: none">The water needs of the Project are driven by aggregate washing requirements and will not increase due to drought conditions.	<ul style="list-style-type: none">This is not expected result in any changes to the Project operations.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment: water can be conserved and proactively managed during drought times
	Amount of Rain	Increasing	<ul style="list-style-type: none">The potential increases in rainfall are readily accommodated by the design floods used to size ditches, culverts, ponds, spillways, etc.These facilities are designed for extremely intense rainfalls that may only occur once every 100 years.	<ul style="list-style-type: none">This is not expected to result in any changes to the Project operationsIncreases in rainfall amounts may increase requirements for maintenance and erosion control measures.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment that the Project design will accommodate these water volumes.
	Frequency	Increasing	<ul style="list-style-type: none">This will not affect the Project since plant designs accommodate for rain events irrespective of their frequency.	<ul style="list-style-type: none">This is not expected to result in any changes to the Project operations	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment
	Rainfall Per Event	Increasing	<ul style="list-style-type: none">As described under “amounts of rain” the Project will be designed to accommodate extreme high rainfall events.	<ul style="list-style-type: none">Increases in rainfall per event may increase requirements for maintenance and erosion control measures.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessmentProject facilities will be designed for extreme rainfall in any events, i.e., of the order of the one in 100 year events.
Snow	Snowfall Amount	Decreasing	<ul style="list-style-type: none">Decreasing snowfall amounts will not impact design	<ul style="list-style-type: none">This may reduce the requirement for snow removal at the Project facilities.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment
Temperature	Freeze-Thaw Events	Decreasing	<ul style="list-style-type: none">This trend will not likely affect the design, since the facilities will be design to accommodate any number of freeze thaw events.	<ul style="list-style-type: none">Less frequent freeze-thaw cycles may reduce repairs and equipment strain.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment
	High Temperatures	Increasing	<ul style="list-style-type: none">Project facilities will be designed to accommodate a temperature range that includes the projected effects of climate change.	<ul style="list-style-type: none">There may be an increased need to provide measures such a shading, fluids, work breaks, etc. for outdoor workers.	<ul style="list-style-type: none">This trend does not change the conclusions of the environmental assessment

Climate Factor Description		Climate Trend	Implication of Climate Change Trends		
			For Project Design	For Project Operations	For the Environmental Assessment
	Warmer Winters	Increasing	<ul style="list-style-type: none"> No special considerations are required. 	<ul style="list-style-type: none"> Winter operations may become slightly easier, resulting in production efficiencies and cost savings. 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.
	Heat Waves	No change	<ul style="list-style-type: none"> No special considerations are required. 	<ul style="list-style-type: none"> There may be an increased need to provide measures such as shading, fluids, work breaks, etc. for outdoor workers. 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.
Other Events	Waves Intensity	Increasing	<ul style="list-style-type: none"> The marine terminal has been designed to accommodate these changes 	<ul style="list-style-type: none"> For safety, operations may be temporarily restricted during high wave periods 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.
	Ice Storm Frequency	Decrease in Fall and Increasing in Winter	<ul style="list-style-type: none"> Project facilities will be designed for ice conditions, especially at the marine terminal 	<ul style="list-style-type: none"> Project will incorporate operational procedures to address with icing conditions 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.
	Sea Level Rise/Storm Surges	Increasing	<ul style="list-style-type: none"> The marine terminal and processing plant will be designed to accommodate the predicted rise in sea level 	<ul style="list-style-type: none"> An Emergency Action Plan will be developed to prepare for and react to severe weather events. 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.
Wind	Speeds	Increasing	<ul style="list-style-type: none"> Project facilities will be designed for high wind velocities, especially at the marine terminal 	<ul style="list-style-type: none"> For safety, operations at the marine terminal may be temporarily restricted during high wind periods 	<ul style="list-style-type: none"> This trend does not change the conclusions of the environmental assessment.

8.7 Conclusion

The Project is located on a relatively exposed southern coastline exposed to northerly winds and considerable wave action. Initial designs have considered prevailing historical conditions, including extreme events, as well the anticipated effects of climate change on key weather variables. As the Project moves into the detailed design stage, additional consideration will be given to the effects of the environment on the Project.

In addition to design factors, potential adverse effects on the Project due to the environment will be mitigated through the monitoring and/or contingency planning described above. Therefore, the effects of the environment on the Project are anticipated to be not significant.

9.0 CUMULATIVE ENVIRONMENTAL EFFECTS

Cumulative environmental effects are residual Project effects combined with the environmental effects of past, present, and future projects. For the Black Point Quarry environmental assessment, the descriptions of the existing environment and of the current condition of each VC already include the effects of current projects occurring within or outside of the Project Area. This assessment also assumes that these existing projects will continue in the future and will have similar effects as are currently observed. The assessment has, therefore, integrated the cumulative effects of these ongoing projects and activities. The cumulative effects assessment presented in Section 9.0 thus focuses on the effects of other future projects and activities.

This is consistent with guidance documentation developed by the CEA Agency: “temporal boundaries...should take into account future physical activities that are certain and reasonably foreseeable, and the degree to which the environmental effects of these physical activities will overlap those predicted from the designated project” (CEAA 2013).

With respect to identifying potential cumulative effects, guidance provided during the review of previous environmental assessments in other jurisdictions has indicated that

1. there must be a measurable environmental effect of the project being proposed;
2. the environmental effect must be demonstrated to interact cumulatively with the environmental effects from other projects or activities; and
3. it must be known that the other projects or activities have been, or will be, carried out and are not hypothetical. That is, there must be some *probability* the cumulative environmental effect will occur rather than simply a *possibility*.

9.1 Project Identification

Information regarding upcoming projects was obtained from a review of new projects listed on the NSE Environmental Assessment Division website and well as the CEA Agency’s online registry. In addition, a generalized internet search was used to identify other anticipated projects. From these information sources, the following projects were identified.

9.1.1 *Planned and Reasonably Certain*

Chedabucto Aggregates Quarry Expansion (Halfway Cove, Guysborough Co.)

Chedabucto Aggregates Limited in September 2014 registered the Chedabucto Aggregates Quarry Expansion for environmental assessment. Approval was granted in November 2014. The project is located approximately 13 km southeast of Guysborough. The proposed expansion is scheduled for 2015; production levels and operations are not expected to increase as a result of the proposed expansion.

Goldboro Liquefied Natural Gas Project (Goldboro, Guysborough Co.)

Pieridae Energy proposes to construct a natural gas liquefaction plant and marine terminal in Goldboro, Guysborough County. On March 21, 2014 the project was approved with conditions and the project is currently in the Front End Engineering and Design phase. On-going land and marine based studies are currently underway at the project site.

Mahe Melford Container Terminal (Melford, Guysborough Co)

Melford International Terminal is proposing to develop a 315-acre container terminal and intermodal rail facility in Melford on the Strait of Canso. Construction timelines are uncertain but the terminal may be operating by late 2015 or early 2016 (reported November 2013). In late 2014 the Nova Scotia Minister of the Environment authorized an extension for the commencement of project work: the Proponent must, on or before October 23, 2016, commence work on the project unless granted an extension by the Minister.

Bear Head Liquefied Natural Gas Project (Port Hawkesbury, Cape Breton)

The Bear Head project near Port Hawkesbury received EA approval in 2004. Construction on the LNG facility began in 2005, but ceased when Texas-based Anadarko could not find a natural gas supply to import to the terminal. In July 2014, the company Liquefied Natural Gas Ltd. announced it has purchased the project (reported July 2014). In November 2014, Liquefied Natural Gas Ltd. announced plans to double the capacity of the proposed liquefaction and export terminal from 4 mtpa to 8 mtpa. A final investment decision on the Bear Head project is expected in late 2015 to 2016, and the facility could be in commercial operation in late 2018 to 2019 (reported November 2014).

9.1.2 *Announced and Uncertain*

H-Energy Liquefied Natural Gas Project (Melford, Guysborough Co)

H-Energy has announced its intention to develop a liquefied natural gas export facility at Melford. The development will be located within the Melford Industrial Land Reserve. A final decision on whether to proceed with the venture will be made by mid-2016 (reported July 2014).

Given the uncertainty associated with Mahe Melford Terminal, the Bear Head and the H-Energy LNG proposals, these projects were not considered in the cumulative effects assessment.

9.2 Cumulative Assessment Methodology

In order to identify potential overlapping projects and systematically assess the likely cumulative effects for each VC, the Project team:

1. Researched the status of future planned or anticipated projects that could overlap in time or space with the Project; and
2. Defined the spatial and temporal boundaries that would be used to assess the degree and significance of the overlap (i.e., the cumulative effect) for each VC.

9.3 Spatial and Temporal Boundaries

Residual effects are predicted for almost all VCs, even following the application of mitigation measures to limit or eliminate these effects. Given this, all VCs were examined for the potential to contribute to cumulative effects. At the same time, the spatial and temporal boundaries applied for each Black Point VC are maintained, since the use of these boundaries for the cumulative effects assessment provides consistency to the analysis.

Once future projects were identified, the infrastructure and activities associated with these projects were reviewed to determine the likelihood that potential effects on VCs at these projects would overlap in space with the VCs assessed for the Black Point Project. If an effect was likely, then these effects were further examined as to their potential to overlap in time (temporal overlap) with Black Point effects. Where an overlap of temporal boundaries was noted, the assessment determined if type of effects would be similar or different in nature or magnitude.

9.4 Cumulative Effects Assessment

9.4.1 Projects Retained

Chedabucto Aggregates Quarry Expansion

Chedabucto Aggregates quarry is located near Halfway Cove approximately 17 km west of Black Point. The quarry produces aggregate for the local building and paving industries, and transports its aggregate to these markets by truck. Given the distance from the Project Area, and the limited scale of quarrying activities associated with the expansion, no overlap in space between the environmental effects produced at Chedabucto Aggregates and the Black Point Project is expected. Therefore, no cumulative effects are anticipated.

Goldboro Liquefied Natural Gas Project

The Goldboro LNG project is located on Nova Scotia's eastern shore, approximately 45 km southwest the Black Point Project. The project is associated with a number of residual environmental effects but most of these effects are not considered to be significant. The project's GHG emissions could be regionally significant when combined with other large, regional GHG emitters, but the Black Point Project is not a significant GHG producer. Vessel traffic to the Goldboro marine terminal will remain many kilometres from Chedabucto Bay. Under these circumstances, there is no overlap in space between the effects produced at Goldboro and those expected at Black Point. Given this, no cumulative effects are anticipated.

Maher Melford Container Terminal and Bear Head Liquefied Natural Gas Projects

The proposed Melford International Terminal (MIT) will be located 23 km from Black Point within the Strait of Canso and will include a wharf and container storage area. The 950 m long wharf will be large enough to berth three post-Panamax container ships or two super post-Panamax ships at one time (AMEC 2008). As noted, construction is currently expected to begin no later than October 2016. Initially 95-150 ships will visit the terminal each year depending on vessel size, increasing to 260 vessels per year at full capacity, again depending on the size of each vessel time (AMEC 2008).

The Bear Head Liquefied Natural Gas Project is located within the Strait of Canso in the Point Tupper/Bear Head Industrial Park, approximately 30 km northwest of the Black Point Project. Initial phases of the project, which may begin in late 2016 or 2017, involve the construction and operation of a 7.5 mtpa capacity LNG terminal with a natural gas send out capacity of 1,000 million standard cubic feet per day, later expanding to 1,500 million standard cubic feet per day. Pier and berthing facilities would be designed to accommodate LNG carriers up to 250,000 m³ in capacity with a ship draft of approximately 13.5 m (JWEL 2004).

There will be approximately 75-135 ships per year (JWEL 2004). A vessel will be delivering to the terminal every 5 days if the project employs 70 vessels per year, and every 2 or 3 days if 135 vessels are employed per year.

9.4.2 Interacting or Overlapping VCs

Given their relative proximity and location with respect to the Black Point Project site, certain aspects (i.e., valued components or VCs) of the Bear Head LNG and the Maher Melford Container Terminal projects are expected to overlap in space and time with VCs retained for the Black Point Project. These VCs include:

Shipping and Navigation: Black Point Project vessels will share space within the traffic separation scheme east and north of the Canso Ledges and in addition, may require anchorage sites within Chedabucto Bay during periods of adverse weather. This may result in a potential cumulative adverse effect on navigational safety. At the same time, the Black Point Project will employ the same tug boats and pilots that will be needed to serve vessels calling at Bear Head LNG and the Maher Melford Container Terminal projects, resulting in positive economic benefits to these services.

Local Economy, Land and Resource Use: the Black Point project will draw from the same general labour pool that will serve for construction of the Bear Head LNG and the Maher Melford Container Terminal projects. This will result in increased economic activity within the region but may also result in short term labour shortage in specialized trades. As noted, positive economic benefits may accrue to tug boat operators, their suppliers and the pilots needed during the construction and operation of these three projects.

9.4.3 Mitigation Measures

With respect to **Shipping and Navigation**, the vessels used to transport aggregate will not be operated by Proponent crews and so mitigation of potential vessel collisions is, to a large extent, outside of the control of the Proponent. Nevertheless, the Proponent will review the safety and environmental records of shipping contractors prior to engaging them, with the aim of employing only the most reputable firms. As a cargo transported by sea, aggregate would not cause

significant adverse effects to the marine environment in the event of a vessel collision or sinking.

Marine traffic within Chedabucto Bay managed by the Canadian Coast Guard and the Proponent will communicate with the MCTS to the extent requested or required during adverse weather conditions. To the extent applicable, the Proponent will also

- Comply with the Eastern Canada Vessel Traffic Services Zone Regulations of the *Canada Shipping Act*;
- Comply with navigational and operational requirements of Atlantic Pilotage Authority and Coast Guard; and
- As needed, provide marine vessel volumes and schedules to marine management operators responsible for traffic movement; and

With respect to **Local Economy, Land and Resource Use** the Proponent is committed to meeting with local schools, trade unions and other organizations to describe labour and skill requirements, and to employ a procurement policy that favours local labour markets and suppliers.

9.4.4 Residual Cumulative Effects and Significance

Taking into account the basic mitigation measures described above, the residual adverse cumulative effects expected with respect to Shipping and Navigation are predicted to be insignificant. Cumulative effects to the Local Economy, Land and Resource Use are expected to be positive and potentially significant over the medium to long term.

10.0 PROPOSED COMPLIANCE AND EFFECTS MONITORING PROGRAMS

As the Project moves forward into detailed design, a number of existing monitoring programs will continue so that additional pre-construction baseline data can be gathered. Supplemental monitoring programs will be initiated as needed during construction and operation, primarily to verify the impacts predicted in the EIS. Table 10.0-1 summarizes the mitigation measures presented in Chapter 7 on a VC by VC basis, and lists the monitoring programs designed to verify the predictions made in the assessment. Table 10-2 further elaborates the follow up and monitoring programs for each VC. The precise details of each monitoring program (e.g., monitoring frequency/duration, specific locations, parameters, and reporting) will be determined in consultation with regulatory agencies, but Table 10-2 provides a summary of each program's objectives and methods. All monitoring programs will be described in the Project EMP.

The objectives of the monitoring programs are to:

1. Verify effects predicted in the EIS;
2. Confirm the continuing effectiveness of the proposed mitigation measures;
3. Identify the need for new mitigation measures in response to unanticipated adverse effects; and
4. Ensure compliance with regulatory permits, approvals, and requirements.

Finally, Table 10-3 summarizes the issues raised by the public and the Mi'kmaq over the course of the environmental assessment, describes where the mitigation measures regarding each issue can be found, lists commitments made by the Proponent to address these issues, and summarizes the follow up and monitoring program associated with the concern raised. More

information regarding issues raised during the environmental assessment is presented in Section 11 Consultation and Engagement below.

**Table 10-1:
Proposed Mitigation and Monitoring by VC**

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
Air Quality and Climate Change (7.1)	<ul style="list-style-type: none"> • Regular maintenance of all equipment and emission control devices. • The use of wet suppression on crushers, screens, and conveyor transfer points. Due to high moisture content of the stone, some parts of the process will not need water sprays or additional dust control. • The application of water to the access and haul roads and aggregate stockpiles as needed. • Use of qualified blasting contractors with blast design plans that incorporate dust controls. • Construction of the haul roads using material with low silt content. • Use of a binder substance within the dust suppression application (e.g. calcium chloride) during drier periods to aid in keeping the roads moist for longer periods of time, when necessary.. • Use adaptive management to adjust dust control measures and/or operating conditions to account for changing conditions that affect dust control. Some of the control measures that will be implemented will include: <ul style="list-style-type: none"> ○ Increase in watering frequency of haul roads and stock piles. ○ Application of dust suppressants to the haul and access roads. ○ Reduction in allowable speed on haul and access roads. ○ Restriction or suspension of operation of part or all of the processing plant until dust can be controlled. ○ Suspension or modification of overburden handling activities. ○ Addition or modification of dust suppression systems to address specific points where dust is being generated, including spray nozzle additions and/or modifications. ○ Modify operation and dust controls during high wind events (>30 km/h) to control dust, if it cannot be controlled suspend operation until it can. • Utilize multi-passenger vehicles to transport crew when possible. • Use high quality, ultra-low sulphur diesel fuels or standard unleaded gasoline for mobile equipment at the operation. (Note: Ships will not be refuelled at the site; vessel fuel type is not within the Proponent's control). • Reduce idling and shut off equipment when parked unless it is required to operate due to safety considerations, inspection requirements or maintenance activity. • Turn off equipment that is idling and not in use. • Utilize drill rig that has dust suppression incorporated into its design. • Apply water to shot rock pile as needed to reduce emissions from loading and conveyance of material to the process. • Ships must comply with International Marine Organization limits on NO_x, VOC, and SO₂ but enforcement is the responsibility of Transport Canada. • Optimize load times to limit auxiliary engine idling on ships at dock. 	<ul style="list-style-type: none"> • Daily dust and weather monitoring as described in the Environmental Management Plan. • Regular individual worker / workplace health and safety testing. • Agency-requested ambient air quality testing or monitoring as required. • Implementation of a complaints log / response protocol at the site office.

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
Noise and Vibration (7.2)	<ul style="list-style-type: none"> • Include noise specifications in equipment procurement practices • Place as much distance as possible between the plant or equipment and residences. • Maximize shielding from quarry walls, buildings and stockpiles as noise barriers. • Use natural landforms as noise barriers. • Include in tenders, subcontractor agreements and work method statements clauses that assure the minimization of noise and compliance with directions from management to minimize noise. • Regularly train workers and contractors to use equipment in ways that minimize noise. • Ensure that site managers periodically check the site, nearby residences and other sensitive receptors for noise problems. • Procure equipment that meets US EPA Category IV air emission standards for off-road diesel equipment which tend to generate less noise than older equipment. • Equipment that operates in the quarry pit should stay in the pit to the extent possible so that the pit walls attenuate the noise levels. • Locate product stockpiles and other structures to the extent possible to attenuate the noise from the processing equipment. • Restrict operating hours for the quarry and processing plants to 16-hours per day so that noise levels are reduced during night time. Additional 8-hours per day maintenance shift will be part of normal operations. • Restrict blasting to daytime hours and weekdays. • Keep truck drivers informed of designated vehicle routes, parking locations, acceptable delivery hours and other relevant practices (e.g. minimizing the use of engine brakes and engine idling). • Minimize the use of reversing alarms by designing the site layout to avoid reversing. • Provide information/advance notification to neighbors before and during construction through media such as letterbox drops or meetings; • Upon request, residents will be alerted to upcoming production shots (blasts) via automated telephone notifications ("robo-calls"). <p><u>Night-time Mitigation Measures</u></p> <ul style="list-style-type: none"> • Minimize the need for reversing alarms. • Avoid metal-to-metal contact on equipment. • Ensure that periods of respite are provided in the case of unavoidable maximum noise level events. 	<ul style="list-style-type: none"> • As required by the NSE Pit and Quarry Guidelines, all blasts will be monitored to establish concussion and vibration levels. This is consistent with the Proponent's standard operating practices at all quarries. • As required by NSE, sound level monitoring will be undertaken at the property boundary or elsewhere as directed during daytime, evening and night-time to verify compliance with the Pit and Quarry guidelines. • As part of the workplace health and safety program, noise monitors will be attached to workers on a regular basis to measure and monitor noise exposure over an eight hour shift.
Ambient Light (7.3)	<ul style="list-style-type: none"> • Use full cut off luminaires where no light is emitted above the horizontal plane, where practical and where they don't comprise worker safety. • Use only the lights needed to meet local lighting objectives. • Where practical Minimize glare by keeping the main beam angle less than 70 degrees. • Use floodlights with asymmetric beams where possible. • Direct the site lighting away from residential properties. • Where possible position lights as far away from site boundaries as practical. 	<ul style="list-style-type: none"> • Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. • The Environmental Management Plan will include instructions on implementing the protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) for responding to avian strandings related to activities in the marine environment.

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<ul style="list-style-type: none"> Where possible, keep lighting at low heights to reduce the chance of illuminating migrating birds. Pole mounted lighting will be pointed downward and shielded from the top and sides. To the extent possible, low intensity lighting will be used rather than high intensity lighting. Lights placed on the outside of the quarry work areas will be kept as low as possible and correctly aimed to prevent lighting non-essential areas. Lights for the marine terminal will be chosen and aimed to prevent where possible light shining directly into the water. Marine terminal lighting will be controlled so that minimal lighting will be used when the terminal is not in operation. If lighting is required at the perimeter of the site it will be aimed inward to prevent off site light trespass. Temporary lighting used during construction will be focussed on the intended work area and will be shielded to minimize spillage. To reduce night time ambient lighting effects, operations will be routinely monitored so that lighting can be switched off by work area when it is not needed. Consideration will be given to using light sources such as directional LEDs to give a better spread of lighting and reduce the overall intensity of the lighting systems. Consideration will be given to selecting lights that have a lesser effect on the wildlife to help reduce lighting effects on nocturnal species. 	<ul style="list-style-type: none"> Nightly site inspections will reveal opportunities for light reduction.
Geology, Soil & Sediment Quality (7.4)	<ul style="list-style-type: none"> Standard mitigation measures to manage acid generating rock, including the control and containment of drainage and the management of excavated rock as per NSE regulation. Sloping of the processing plant area to the south to collect surface water within the sedimentation ponds, prevent discharge to the ocean. Environmental Management Plan that describes standard ARD control measures. The Environmental Management Plan will incorporate an Erosion and Sediment Control Plan to ensure drainage is properly managed and control structures inspected and a Stormwater Management Plan that describes the construction and operation drainage swales and stormwater management ponds. 	<ul style="list-style-type: none"> The acid generating potential of bedrock will be assessed at the beginning of construction as per the <i>Nova Scotia Sulphide Bearing Material Disposal Regulations</i>. Discharge will be monitored through a Surface Water Monitoring Program elaborated within the Environmental Management Plan.
Groundwater Resources (7.5)	<ul style="list-style-type: none"> Since no impacts to groundwater users are expected, no mitigation is proposed To mitigate reductions in groundwater flows that supply nearby wetlands, implement a Wetland Compensation Plan for wetlands damaged due to the Project. 	<ul style="list-style-type: none"> The groundwater wells will be monitored as part of the Groundwater Monitoring Program elaborated within the Environmental Management Plan.
Marine and Surface Water Resources (7.6)	<ul style="list-style-type: none"> Sedimentation ponds will be used near the processing plant while the quarry pit will employ sumps to collect water inflows. Topographic controls (sloping the ground to the south) will ensure that overflow, should it occur, will collect against the south cliff and in the pit, rather than be permitted to discharge directly to the ocean. Double walled and or/fully contained fuel and chemical storage reservoirs will be used. The Environmental Management Plan will include a discrete Erosion and Sediment Control Plan to ensure drainage is properly managed and control structures inspected and a Stormwater 	<ul style="list-style-type: none"> Discharge will be monitored through a Surface Water Monitoring Program elaborated within the Environmental Management Plan. The success of the Wetland Compensation Plan will be monitored over time as determined in collaboration with NSE; other water features not directly included in the Plan will be inspected to detect hydrological changes potentially caused by the Project – these inspections will be outlined in the Plan.

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<p>Management Plan that describes the construction and operation drainage swales and stormwater management ponds.</p> <ul style="list-style-type: none"> • The EMP will also include an Emergency Response and Spill Contingency Plan combined with incident prevention and emergency response training to minimize the risk of accidental spills and to rapidly react to any incident that may occur. The Emergency Response and Spill Contingency Plan will include spill dispersion modelling in the marine environment to aid in rapid and effect emergency response. • The Proponent will contract with a local emergency response consultant to ensure that additional resources and expertise are available in the event of an accidental spill in the marine environment. • To mitigate reductions in surface water flows that supply nearby wetlands, implement a Wetland Compensation Plan for wetlands damaged due to the Project. 	
Terrestrial Ecosystems, Habitat and Vegetation (7.7)	<ul style="list-style-type: none"> • A general set of environmental mitigation measures will be defined in the Environmental Management Plan which will include an Erosion and Sediment Control Plan, a Stormwater Management Plan and an Emergency Response and Spill Contingency Plan. • Minimize the Project footprint. • Mark Project boundaries to prevent accidental impacts outside the work area. • Remove/ and salvage topsoil; store separately and reuse for site restoration. • Dust-prevention and abatement measures outlined above will also protect local flora and habitats. • Stabilize and rehabilitate areas of disturbance. • Use local native vegetation in restoration; consideration will be given to the preferential use of vegetation types of interest to the Mi'kmaq. • Vegetation management will be conducted by mechanical cutting (e.g., mower, brush cutter); • Mitigation measures for the protection of watercourses (see Section 7.6 and 7.10) will help to protect terrestrial and freshwater aquatic vegetation and habitats. 	<ul style="list-style-type: none"> • The Environmental Management Plan will establish monitoring/inspection plans to ensure protective mitigation measures are implemented and effective. • Daily inspection and record keeping will be described in the EMP. • A Rehabilitation Plan will be prepared to guide habitat restoration following closure
Wetlands (7.8)	<ul style="list-style-type: none"> • Mitigation developed for surface water quality will also protect wetlands (Sections 7.6). • Mitigation against the potential effects of spills, malfunctions and accidents are described in Section 7.18. • Wetlands will be avoided to the extent feasible during Project planning. • Where wetlands cannot be avoided, the Project footprint in the wetland area will be minimized. • A wetland alteration permit will be obtained from NSE prior to construction. • Where a permanent loss of wetland function is identified, a Wetland Compensation Plan will be developed, subject to approval by NSE. • Maintain a 30 m buffer around all undisturbed wetlands. • Where the access road cuts across diffuse natural drainage paths culverts or drainage swales of sufficient size will be installed to maintain water flow at pre-construction levels. • To the extent feasible, clean site runoff will be managed so that the amount of water entering adjacent wetlands is similar to pre-construction levels. • Runoff collected along the roads will not be allowed to enter directly into wetlands, but shall be directed into vegetation buffers around wetlands. 	<ul style="list-style-type: none"> • Efficacy of the erosion and sediment control measures will be monitored as outlined in the Environmental Management Plan. • Monitoring of new or enhanced wetlands will be undertaken as per the Wetland Compensation Plan. • Other water features not directly included in the Plan will be inspected to detect hydrological changes potentially caused by the Project – these inspections will be outlined in the Plan.

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<ul style="list-style-type: none"> Integration of existing/remnant wetlands into the quarry's stormwater management system will be considered in the Stormwater Management Plan and in the Environmental Management Plan. Implement Erosion and Sediment Control Plan. Uncontaminated drainage will be directed away from areas under construction. Vegetation management in or near wetlands will be conducted by cutting (i.e., no use of herbicides). Dust-prevention and abatement measures outlined above will also protect wetlands. 	
Terrestrial Wildlife (7.9)	<ul style="list-style-type: none"> Minimize the Project footprint. Implement dust-prevention and dust abatement measures described above. Implement a Wetland Compensation Plan. Instruct workers to maintain good housekeeping practices and not leave out any food or garbage to avoid attracting wildlife. To minimize impacts on nesting landbirds, clearing will take place outside of the breeding season for most bird species (April 1 to September 1). If some clearing is necessary during the breeding season the Proponent will assess if the work can be undertaken without contravention of the <i>Migratory Birds Convention Act</i> and a contingency plan developed in consultation with CWS in order to maintain compliance with the Act. If an Osprey, Bald Eagle or Northern Goshawk nest is found, even outside of the breeding season, a buffer zone will be placed around the nest and clearing will only occur outside of the buffer zone. To discourage ground-nesting or burrow-nesting species, no large piles or patches of bare soil will be left uncovered or un-vegetated during the breeding season. Should any ground- or burrow-nesting species initiate breeding activities on stockpiles or exposed areas, the Proponent will establish a 20 m buffer around the nest location and contact EC-CWS for further advice. Noise suppression equipment such as mufflers on mobile equipment and fixed/portable engines will be maintained in original OEM working condition The duration of noise disturbance will be minimized. Lighting will be restricted to areas where it is necessary. To minimize interference of nesting activities, workers will be asked to refrain from entering undisturbed habitat areas where no work is done. In the event that impacts on migratory birds are detected during construction, further mitigation will be developed in consultation with NSDNR and EC. Standard mitigation measures for noise (including blasting), as outlined in Section 7.2, will minimize impacts on terrestrial fauna. As recommended by EC, ships en route will maintain a minimum distance of at least 300 m from any colony or island occupied by seabirds and waterbirds. To minimize the risk to migrant birds, the minimum amount of pilot warning and obstruction avoidance lighting will be used on tall structures. The use of solid-burning or slow pulsing warning lights at night will be avoided. 	<ul style="list-style-type: none"> Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. The Environmental Management Plan will include provisions describing specific management actions for at risk species (e.g., Mainland Moose, ground- or burrow-nesting species)

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<ul style="list-style-type: none"> • Lighting for the safety of the employees should be shielded to shine down and only to where it is needed, without compromising safety. • Street and parking lot lighting should also be shielded so that little escapes into the sky and it falls where it is required. • The protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) will be used for stranded seabirds. • White lights will be preferred for use on towers or high structures at night, as recommended by the US Fish and Wildlife Service (2003). Solid red or flashing red lights will be avoided as they appear to attract nocturnal migrants more than white flashing lights. • The operation of exterior decorative lights such as spotlights and floodlights, whose function are to highlight features of buildings or to illuminate an entire building, will be avoided unless safety is a factor. • High intensity lights, including floodlights, will be turned off at night outside of working hours, if possible, especially during the spring and fall migration period. • Where feasible, tinted or frosted glass windows will be used in buildings to reduce bird mortality from collisions. 	
Freshwater Species and Habitat (7.10)	<ul style="list-style-type: none"> • As described in the Erosion and Sediment Control Plan, erosion control measures will be implemented to ensure that discharge water quality meets all relevant regulatory standards prior to discharge to receiving environment. • As described in the Stormwater Management Plan, stormwater will be collected in the pit and in ponds near the processing plant to ensure that uncontrolled runoff will not occur. • Overburden stockpiles, fuel and chemical storage facilities, and construction equipment will be located a minimum of 30 m from any pre-development water body. • Flagging tape will be used to delineate temporary work areas and control construction access near retained wetlands and water bodies to protect natural substrates and vegetation contributing to habitat and bank stability; • An Emergency Response Spill Contingency Plan will be prepared to prevent and manage the effects of any malfunctions and accidents. • Creation of a 30 ha freshwater lake within the pit following cessation of quarrying activities. 	<ul style="list-style-type: none"> • Fish habitat assessment and determination of presence/absence is proposed for Reynolds Brook above Hendsbee Lake. If fish are present, then a modest monitoring program is proposed for such time as quarry development begins to divert water away from its natural drainage to the south. This is not expected to occur before year 10 of quarry development. • A Rehabilitation Plan will be prepared to guide habitat restoration following closure <p>During construction and operation monitoring will focus on:</p> <ul style="list-style-type: none"> • Condition and location of erosion and sediment control structures; • Water quality testing of stormwater discharge as outlined in the Surface Water Monitoring Program; and • Ensuring overburden stockpiles, fuel and chemical storage facilities, and construction equipment are a minimum of 30m from any natural water body.
Marine Species and Habitat (7.11)	<ul style="list-style-type: none"> • An Environmental Management Plan will describe the following preventative and mitigation measures: <ul style="list-style-type: none"> ○ Application of appropriate timing windows for all in-water work. ○ Implementation of terrestrial erosion and sediment control measures. ○ Use of surface water monitoring to ensure that quality meets all relevant regulatory standards prior to discharge to receiving environment. • Install overburden stockpiles, fuel and chemical storage facilities a minimum of 30 m from Chedabucto Bay. • Implement an Emergency Response and Spill Contingency Plan for Accidents and Malfunctions. 	<ul style="list-style-type: none"> • Fisheries Offset Program and associated monitoring for effectiveness. • Concussion and ground vibration monitoring during each blast to ensure limits established by DFO for the marine environment are respected.

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<ul style="list-style-type: none"> • If effects from blasting vibrations exceed the DFO thresholds, then a site specific standard to protect fish and an appropriately scaled fish and fish habitat offset plan will be implemented. • Control ballast water release via “<i>Ballast Water Control and Management Regulations</i>” and the requirements as per the International Convention for the control and Management of Ship’s Ballast Water and Sediments. • Implement a Fisheries Offset Program to recreate fish habitat that has suffered “serious harm”. 	
Species at Risk (SAR) and of Conservation Concern (SOCC) (7.12)	<ul style="list-style-type: none"> • Mitigation for potential effects on SAR and SOCC are similar to recommendations for terrestrial or marine fauna as a whole. Standard mitigation measures such as minimization of Project footprint, dust control, emissions control, and monitoring of air quality targets as detailed in Sections 7.7 and 7.1 will be sufficient to protect many SAR and SOCC, if present. • Standard handling and storage procedures for hazardous material, as well as procedures for handling and disposal of contaminated soils (outlined in Section 7.18), will adequately mitigate the potential for exposure of Moose and bird SAR/SOCC to any hazardous materials or contaminated soils. • Strict reporting policies for any suspected hunting activities will help to minimize any potential Moose poaching in the Project area. • Imposing a 50 km/hr speed limit will reduce the potential for vehicle-moose collisions. It will also decrease encounters between humans and Moose. • Exposed soils and soil stockpiles will be adequately covered or vegetated to deter Common Nighthawks from nesting on them. • Should Common Nighthawks initiate breeding, the Proponent will establish a 20 m buffer around the location once identified, and contact CWS for further advice. 	<ul style="list-style-type: none"> • Mainland Moose surveys (presence/absence and use) will be performed annually for up to three years after construction is initiated. • Regular inspections for Common Nighthawk nests.
Local Economy, Land and Resource Use (7.13)	<ul style="list-style-type: none"> • Recreational users will be notified of restricted access by signage at the entrance to the construction site. • Vessels will not be refuelled at the marine terminal and fuel used at the quarry will be kept in double hulled reservoirs or will be placed within secondary containment and will be protected against collision. This helps to minimize the risk of accidents at the terminal. • Navigational safety mitigation measures and emergency response planning measures are presented in Section 7.18.3. • As part of the Environmental Management Plan, implement an Emergency Response and Spill Contingency Plan in advance of any accident or malfunction causing a spill in the marine environment. • The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed. 	<ul style="list-style-type: none"> • None proposed
Tourism and Recreation (7.14)	<ul style="list-style-type: none"> • Recreational users will be notified of restricted access by signage at the entrance to the construction site. • Vessels will not be refuelled at the marine terminal and fuel used at the quarry will be kept in double hulled reservoirs protected against collision. This helps to minimize the risk of accidents at the terminal. 	<ul style="list-style-type: none"> • None proposed

VC	Mitigation	Monitoring (please see Table 10-2 for Monitoring Program Details)
	<ul style="list-style-type: none"> • Navigational safety mitigation measures and emergency response planning measures are presented in Section 7.18.3. • As part of the Environmental Management Plan, implement an Emergency Response and Spill Contingency Plan in advance of any accident or malfunction causing a spill in the marine environment. • The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed. 	
Commercial Fisheries (7.15)	<ul style="list-style-type: none"> • Minimize the impact of construction in the marine environment during and after lobster fishing season to the extent possible. For example: standard construction best management practices and mitigation measures to control onshore sediment release to the marine environment will be implemented (Section 7.6 and Section 7.11). • The quarry site office will be manned 24 hrs/day so that fishermen can telephone to receive information regarding vessel arrival and departures. The phone number can also be used to report loss or damage to gear caused by Project-related vessel traffic. • Construction and regular use of the marine terminal will require a safety exclusion zone around the terminal. Loss of these fishing grounds will be mitigated through the creation of new lobster habitat as described in the Fisheries Offset Program to be established in collaboration with local fishermen and DFO. • Routine communication with potentially affected Mi'kmaq will occur through the CLC or through other means as established by both parties. 	<ul style="list-style-type: none"> • Monitoring terminal operations and fishing access in response to concerns expressed by local fishing community, as needed; • Monitoring of the effectiveness of the marine Fisheries Offset Program for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met.
Archaeological/Heritage Resources (7.16)	<ul style="list-style-type: none"> • Prior to construction, implement a Cultural Resource Management Plan to guide site personnel in the event that archaeological and heritage resources are identified during construction. The Plan specifies a notification procedure if remains are found, and will describe specific preservation measures as needed. • These mitigation measures would be approved by the Minister of the Department of Communities, Culture and Heritage before site construction could begin. • Exploratory excavation will likely be required in those areas that may be disturbed during Project construction. 	<ul style="list-style-type: none"> • Follow up pre-construction excavation to investigate heritage resources that will be lost during project construction • Monitor construction activities near known or suspected cultural resources.
Mi'kmaq Land and Resource Use (7.17)	<ul style="list-style-type: none"> • While there is currently no Mi'kmaq harvesting on the site or in waters immediately adjacent, it is intended that the non-hazardous portions of the Project site and adjacent waters will be accessible to Mi'kmaq for harvesting for flora and fauna for food, social and ceremonial purposes, to the extent this is not precluded by safety consideration • Any future potential Project impacts (environmental, social and economic) on these harvesting activities will be a matter of the formal and regular meetings with the Mi'kmaq community representatives. • In the event that archaeological remains are excavated, recommended guidelines as directed by the Nova Scotia Communities, Culture, and Heritage Coordinator of Special Places will be employed. Should evidence of aboriginal archeological remains be uncovered all activity will cease until Mi'kmaq archaeological experts have had an opportunity to examine the site and determine appropriate action. 	<ul style="list-style-type: none"> • Monitoring of progress and implementation of MOU and any other agreements reached with other First Nation communities. • Mi'kmaq resource harvesting activities will be reviewed with Mi'kmaq representatives at the Community Liaison Committee meetings.

**Table 10-2:
Monitoring Commitments by VC**

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
Air Quality and Climate Change (7.1)	1. Dust and weather monitoring as described in the Environmental Management Plan	At the property boundary and elsewhere as needed where dust is produced.	<ul style="list-style-type: none"> To ensure that on-site dust abatement is effective. To identify activities that may require modification to reduce dust emissions. To document daily conditions that may affect operations and to help respond to reported concerns or complaints. 	<ul style="list-style-type: none"> Visual observations of dust, wind and weather conditions (i.e., inversions, high winds, dry periods) will be recorded daily by site supervisors. Observations entered into a log sheet that is part of the Environmental Management Plan documentation.
	2. Regular individual worker / workplace health and safety testing for dust exposure	Monitoring devices are attached to individual site workers.	<ul style="list-style-type: none"> To monitor exposure to dust in the work environment and ensure worker exposure is below maximum regulated limits at all times. 	<ul style="list-style-type: none"> As part of the workplace health and safety program, a dust dosimeter with air pump is attached to an employee over a typical eight hour shift. Dust collected on the dosimeter's filter paper is weighed to assess worker exposure over time.
	3. Agency-requested ambient air quality testing or monitoring as required.	At the property boundary or elsewhere as directed by the regulatory authority.	<ul style="list-style-type: none"> To ensure that contaminant concentrations are within provincial and federal Air Quality objectives and/or operating permit conditions. 	<ul style="list-style-type: none"> Sampling equipment, methods and frequency as directed by the regulatory authority.
	4. Complaints Log / Response Protocol	At the quarry office	<ul style="list-style-type: none"> To ensure complaints are registered (logged), forwarded to a knowledgeable, and addressed in a timely fashion. 	<ul style="list-style-type: none"> The quarry office telephone number will be manned 24-hours per day. Complaints will be logged and return telephone calls will be made by quarry staff to discuss and address any issues raised.
Noise and Vibration (7.2)	1. Concussion (air blast) and Ground Vibration peak particle velocity monitoring during each blast.	<ul style="list-style-type: none"> Within the property boundary or Concussion: within 7.0 m of the nearest structure not on the property or elsewhere as directed by NSE. Vibration: measured below grade or less than 1.0 m above grade in any part of the nearest structure not located on the property or elsewhere as directed by NSE. 	<ul style="list-style-type: none"> Compliance with the Pit and Quarry Guidelines 	<ul style="list-style-type: none"> All blasts will be monitored as required by the Pit and Quarry Guidelines. This is consistent with the Proponent's standard practices at all quarries. Weather conditions will be observed and recorded on a daily basis to ensure no blasting occurs during a thermal inversion, as required in the Pit and Quarry Guidelines. Monitoring results will be sent to NSE on a monthly basis unless otherwise directed by NSE.
	2. Preparation of a technical blast design	For quarry operations (blasting)	<ul style="list-style-type: none"> Compliance with the Pit and Quarry Guidelines 	<ul style="list-style-type: none"> The blast design must demonstrate the concussion and ground vibration criteria in the Pit and Quarry Guidelines

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
				can be met.
	3. Regular individual worker / workplace health and safety testing for noise exposure	Monitoring devices are attached to individual site workers.	<ul style="list-style-type: none"> To monitor exposure to noise in the work environment and ensure worker exposure is below maximum regulated noise limits at all times. 	<ul style="list-style-type: none"> As part of the workplace health and safety program, noise monitors will be attached to workers on a regular basis to measure and monitor noise exposure over an eight hour shift.
	4. Daily monitoring of Sound Level Limits (night, evening, day) as directed by NSE	At the property boundary or at other locations as directed by NSE	<ul style="list-style-type: none"> Compliance with the Pit and Quarry Guidelines 	<ul style="list-style-type: none"> Methodologies will comply with NSEL's Guidelines for Environmental Noise Measurement and Assessment or other methods as directed by NSE.
	5. Complaints Log / Response Protocol	At the quarry office	<ul style="list-style-type: none"> To ensure complaints are registered (logged), forwarded to a knowledgeable employee, and addressed in a timely fashion 	<ul style="list-style-type: none"> The quarry office telephone number will be manned 24-hours per day. Complaints will be logged and return telephone calls will be made by quarry staff to discuss and address any issues raised.
Ambient Light (7.3)	1. Routine monitoring for dead or injured birds as described in the Environmental Management Plan.	Site wide	<ul style="list-style-type: none"> To verify the effectiveness of mitigation measures related to lighting 	<ul style="list-style-type: none"> Daily inspections and record keeping. In the event of the mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds, EC-CWS will be notified within 24 hours. Notification will include the name and location of the facility, number and species of birds affected, meteorological conditions during the previous night(s), status of lights, and details of any other factor which may have influenced the event. If the need arises and dead birds are found on routine inspection and documentation as described in the EMP then EC-CWS will be contacted to help develop additional mitigation measures. The Environmental Management Plan will include instructions for implementing the protocol "Best practices for stranded birds encountered offshore Atlantic Canada" (EC 2014e) for responding to avian strandings related to activities in the marine environment.
	2. Routine site inspections to look for light reduction opportunities	Site wide	<ul style="list-style-type: none"> Routine site inspections identify light reduction opportunities, especially reduction of light levels in non-active work areas, and/or redirection of lighting installation. 	<ul style="list-style-type: none"> Nightly Inspections and record keeping will be described in the Environmental Management Plan.
	3. Complaints Log / Response Protocol	At the quarry office	<ul style="list-style-type: none"> To ensure complaints are registered (logged), forwarded to a 	<ul style="list-style-type: none"> The quarry office telephone number will be manned 24-hours per day. Complaints will be logged and return

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
			knowledgeable employee, and addressed in a timely fashion	telephone calls will be made by quarry staff to discuss and address any issues raised.
Geology, Soil & Sediment Quality (7.4)	1. Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To ensure compliance with discharge water quality objectives and to protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
	2. Surface Water Quality Monitoring Program	Discharge from the sedimentation ponds	<ul style="list-style-type: none"> To prevent discharge of sediment laden, low pH water and ensure compliance with discharge water quality objectives as listed in the operating permit. 	<ul style="list-style-type: none"> Water sampling will be undertaken as described in the operating permit conditions. Samples will be taken using standard water sampling methods such as found in, for example, Protocols Manual for Water Quality Sampling in Canada (CCME 2011).
	3. Assessment of acid generation potential of bedrock in the processing plant area	All bedrock that will be disturbed during construction of the processing plant	<ul style="list-style-type: none"> To ensure potentially acid generating rocks are identified and if present, managed according to provincial regulation. 	<ul style="list-style-type: none"> The acid generating potential of bedrock will be assessed at the beginning of construction through a sampling and analytical program as per the Nova Scotia <i>Sulphide Bearing Material Disposal Regulations</i>.
Groundwater Resources (7.5)	1. Groundwater Monitoring Program	Adaptive monitoring program employing up to ten well pairs located within property boundaries and on adjacent lands up to 400 m from the quarry boundary.	<ul style="list-style-type: none"> To verify drawdown and water quality predictions made in the assessment. 	<ul style="list-style-type: none"> The Groundwater Monitoring Program (Appendix A) proposes the progressive installation over time of up to 10 monitoring well pairs (deep and shallow), each to be monitored quarterly for a minimum of two years. Two baseline water quality samples will be taken per year in each well, for a minimum of two years. As an adaptive program, initial results will inform the location and monitoring activities at new wells, and initial results will determine whether continued monitoring is required after two years.
Marine and Surface Water Resources (7.6)	2. Surface Water Quality Monitoring Program	Discharge from the sedimentation ponds.	<ul style="list-style-type: none"> To prevent discharge of sediment laden, low pH water and ensure compliance with discharge water quality objectives as listed in the operating permit. 	<ul style="list-style-type: none"> Water sampling will be undertaken as described in the operating permit conditions. Samples will be taken using standard water sampling methods such as found in, for example, Protocols Manual for Water Quality Sampling in Canada (CCME 2011).
	3. Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To ensure compliance with discharge water quality objectives and to protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
	3. Wetland Compensation Plan	Site wide and Affected Area	<ul style="list-style-type: none"> To replace wetlands damaged or destroyed during the course of the Project. To monitor indirect Project effects on nearby watercourses and 	<ul style="list-style-type: none"> The Wetland Compensation Plan based on a signed Letter of Understanding between the Proponent and NSE will be developed in collaboration with NSE and other stakeholders. The Plan will be based on the NS Wetland Conservation Policy and other guidance

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
			wetlands	documents and implemented over the life of the Project as the quarry gradually expands. <ul style="list-style-type: none"> The Wetland Compensation Plan will include follow up monitoring of newly created or restored wetlands. As part of the Wetland Compensation Plan a wetland and surface water feature inspection program will be implemented to confirm hydrological predictions made in the environmental assessment and to identify any unforeseen wetland or watercourse impacts so these impacts can be addressed or compensated.
Terrestrial Ecosystems, Habitat and Vegetation (7.7)	1. Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
Wetlands (7.8)	1. Wetland Compensation Plan	Site wide and Affected Area	<ul style="list-style-type: none"> To replace wetlands damaged or destroyed during the course of the Project. To monitor indirect Project effects on nearby watercourses and wetlands 	<ul style="list-style-type: none"> The Wetland Compensation Plan, based on a signed Letter of Understanding between the Proponent and NSE, will be developed in collaboration with NSE and other stakeholders. The Plan will be based on the NS Wetland Conservation Policy and other guidance documents and implemented over the life of the Project as the quarry gradually expands. The Wetland Compensation Plan will include follow up monitoring of newly created or restored wetlands. As part of the Wetland Compensation Plan a wetland and surface water feature inspection program will be implemented to confirm hydrological predictions made in the environmental assessment and to identify any unforeseen wetland or watercourse impacts so these impacts can be addressed or compensated. Any unforeseen wetland or watercourse impacts.
	2. Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
Terrestrial Wildlife (7.9)	1. Routine monitoring for dead or injured birds as wells as ground- or burrow-nesting species, as described in the Environmental Management Plan.	Daily	<ul style="list-style-type: none"> To verify the effectiveness of mitigation measures related to lighting and at-risk species 	<ul style="list-style-type: none"> Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. The Environmental Management Plan will include for

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
				ground- or burrow-nesting species. Should these species initiate breeding on stockpiles or exposed areas, periodic monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area and the nest site is found to be inactive.
	2. Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To ensure compliance with discharge water quality objectives and to protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
Freshwater Species and Habitat (7.10)	1. Fish habitat assessment and determination of fish presence/absence	Reynolds Brook above Hendsbee Lake.	<ul style="list-style-type: none"> To determine if fish are present and by extension, if follow up monitoring is required. 	<ul style="list-style-type: none"> Determination of fish presence/absence; characterisation of fish habitat. If present, then: Obtain seasonal water quality samples (spring, fall, winter) as baseline for future comparisons. Establish stage/discharge conditions to determine if future quarry operations that will potentially reduce flow can in fact be detected in Reynolds Brook.
	2. Surface Water Quality Monitoring Program	Discharge from the sedimentation ponds.	<ul style="list-style-type: none"> To prevent discharge of sediment laden, low pH water and ensure compliance with discharge water quality objectives as listed in the operating permit. 	<ul style="list-style-type: none"> Water sampling will be undertaken as described in the operating permit conditions. Samples will be taken using standard water sampling methods such as found in, for example, Protocols Manual for Water Quality Sampling in Canada (CCME 2011).
	3. Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To ensure compliance with discharge water quality objectives and to protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
Marine Species and Habitat (7.11)	1. Marine Fisheries Offset Program	Following discussions with DFO and local fishermen, offset projects will likely be established immediately east or west of the Project site.	<ul style="list-style-type: none"> To recreate fisheries habitat lost or damaged due to construction of the marine terminal 	<ul style="list-style-type: none"> Monitoring of the success of the marine Fisheries Offset Program for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met.
	2. Concussion and ground vibration monitoring during each blast..	Within the property boundary	<ul style="list-style-type: none"> Ensure noise limits established by DFO for the marine environment are respected. 	<ul style="list-style-type: none"> Continuous-operation seismographs designed to record blast vibrations
	3. Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan, Stormwater Management Plan.	Site wide	<ul style="list-style-type: none"> To ensure compliance with discharge water quality objectives and to protect sensitive marine and terrestrial habitats and species. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan, Erosion and Sediment Control Plan and Stormwater Management Plan will be included in the Environmental Management Plan.
	4. Surface Water Quality Monitoring	Discharge from the sedimentation	<ul style="list-style-type: none"> To prevent discharge of sediment 	<ul style="list-style-type: none"> Water sampling will be undertaken as described in the

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
	Program	ponds.	laden, low pH water and ensure compliance with discharge water quality objectives as listed in the operating permit.	operating permit conditions. Samples will be taken using standard water sampling methods such as found in, for example, Protocols Manual for Water Quality Sampling in Canada (CCME 2011).
Species at Risk (SAR) and of Conservation Concern (SOCC) (7.12)	1. Mainland Moose monitoring program establish as part of the Environmental Management Plan	Within the property boundary extending into adjacent moose habitats	<ul style="list-style-type: none"> To supplement current understanding of moose use of the Project area. 	<ul style="list-style-type: none"> Mainland Moose Surveys will be performed annually for up to three years after construction is initiated. Moose survey methodologies will be based on established NSDNR protocols and elaborated within the Environmental Management Plan.
	2. Inspection of Common Nighthawk nests, if nesting birds are present	Within the site where nests are found.	<ul style="list-style-type: none"> To ensure nesting birds remain undisturbed until chicks have fledged. 	<ul style="list-style-type: none"> Should Common Nighthawks initiate breeding, daily monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area. Inspection and other protective measures will be described within the Environmental Management Plan.
Local Economy and Land Use (7.13)	1. Emergency Response and Spill Contingency Plan / emergency response training	Site wide	<ul style="list-style-type: none"> To ensure the necessary resources are in place in effectively respond to an emergency event. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan (which will include marine spill dispersion modelling) will be included in the Environmental Management Plan. The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed.
Tourism and Recreation (7.14)	1. Emergency Response and Spill Contingency Plan / emergency response training	Site wide	<ul style="list-style-type: none"> To ensure the necessary resources are in place in effectively respond to an emergency event. 	<ul style="list-style-type: none"> Details of the Emergency Response and Spill Contingency Plan (which will include marine spill dispersion modelling) will be included in the Environmental Management Plan. The Proponent will contract with a local emergency response organisation to ensure supplementary emergency resources are available if needed.
Commercial Fisheries (7.15)	1. Marine Fisheries Offset Program	Following discussions with DFO and local fishermen, offset projects will likely be established immediately east or west of the Project site.	<ul style="list-style-type: none"> To recreate fisheries habitat lost or damaged due to construction of the marine terminal 	<ul style="list-style-type: none"> Monitoring of the success of the marine Fisheries Offset Program for a minimum of three years during and after marine terminal construction until it can be demonstrated that the program objectives have been met.
	2. Help Line / Complaints Log / Response Protocol	At the quarry office	<ul style="list-style-type: none"> To ensure shipping schedules and marine terminal operations are known to fishermen. To address concerns or complaints associated with operations and damage or loss of fishing gear. 	<ul style="list-style-type: none"> The quarry office telephone number will be manned 24-hours per day. Fishermen can contact the quarry supervisor to learn shipping schedules. Any concerns expressed with respect to terminal or shipping operations, including damage to gear, will be logged and return telephone calls will be made by quarry

Valued Component (EIS Section)	Follow Up and Monitoring Programs	Monitoring Locations	Program Objective	Methods and Frequency
				staff to discuss and address any issues raised.
Archaeological/ Heritage Resources (7.16)	1. Pre-construction archaeological excavation	At those archaeological sites in the processing plant area that will be disturbed/destroyed during construction.	<ul style="list-style-type: none"> To investigate and preserve heritage resources that will be lost during Project construction. To ensure the long term protection and preservation of heritage resources not directly affected by the Project. 	<ul style="list-style-type: none"> The methods used for the archaeological excavations will require approval by Minister of the Department of Communities, Culture and Heritage prior to initiation.
	2. Cultural Resources Management Plan	Site wide	<ul style="list-style-type: none"> To ensure that any additional cultural heritage resources found during construction are managed according to provincial regulation. 	<ul style="list-style-type: none"> The Cultural Resources Management Plan will be elaborated within the Environmental Management Plan and will following guidance provided by the Minister of the Department of Communities, Culture and Heritage.
Mi'kmaq Land and Resource Use (7.17)	1. Ongoing dialogue with Mi'kmaq representatives	Not applicable	<ul style="list-style-type: none"> To ensure that traditional land and resource practices, including those in the marine environment, can continue on the property and marine waters to the extent this can be done safely. 	<ul style="list-style-type: none"> Discussions to occur through the presence of Mi'kmaq representatives on the Community Liaison Committee or other forums established between the Proponent and Mi'kmaq representatives.

**Table 10-3:
Issues Raised During the Assessment and Proponent Commitments**

Issue or Concern	Mitigation	Proponent Commitments	Follow Up Program
Raised by the Public			
Biophysical Subjects			
1. Effects of the quarry on groundwater quality, including potable water wells	<ul style="list-style-type: none"> Section 7.5 and Table 10-1 	<ul style="list-style-type: none"> Proponent presented groundwater findings at a Community Liaison Committee meeting. Groundwater discharge to surface waterbodies will meet Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life for all parameters meeting these standards prior to development. Potable groundwater will meet the criteria listed in Guidelines for Canadian Drinking Water Quality for all parameters meeting the Guidelines prior to development. Reductions to groundwater flow in the Affected Area will not exceed 20%. 	<ul style="list-style-type: none"> Groundwater Monitoring Program (Hydrogeology Technical Report, Appendix A)
2. Changes in ambient noise levels	<ul style="list-style-type: none"> Section 3.3.9, Section 7.2 and Table 10-1. 	<ul style="list-style-type: none"> Maximum noise and vibration limits listed in the <i>Pit and Quarry Guidelines</i> will be met at the property boundary. The Proponent will respect all provisions in the provincial <i>Workplace Health and Safety Regulations</i> made under the Occupational Health and Safety Act. The Proponent will provide the telephone number of the on-site quarry office and document all complaints within a Complaints Log. All callers will receive a return phone call to ensure issues are documented and addressed. 	<ul style="list-style-type: none"> Concussion (air blast) and Ground Vibration peak particle velocity monitoring during each blast. Preparation of a technical blast design Regular individual worker / workplace health and safety testing for noise exposure Daily monitoring of Sound Level Limits (night, evening, day) as directed by NSE Complaints Log / Response Protocol
3. Changes in ambient air quality	<ul style="list-style-type: none"> Section 7.1 and Table 10-1. 	<ul style="list-style-type: none"> Air emissions will comply with the Nova Scotia <i>Air Quality Regulations</i> and meet the National Ambient Air Quality Objectives under CEPA, 1999. The Proponent will respect all provisions in the provincial <i>Workplace Health and Safety Regulations</i> made under the Occupational Health and Safety Act. The Proponent will provide the telephone number of the on-site quarry office and document all complaints within a Complaints Log. All callers will receive a return phone call to ensure issues are documented and addressed. 	<ul style="list-style-type: none"> Dust and weather monitoring as described in the Environmental Management Plan Regular individual worker / workplace health and safety testing for dust exposure Agency-requested ambient air quality testing or monitoring as required. Complaints Log / Response Protocol
4. Changes in ambient light levels	<ul style="list-style-type: none"> Section 3.3.9, Section 7.3 and Table 10-1. 	<ul style="list-style-type: none"> Lighting will be restricted to that necessary to ensure worker safety. Light will not interfere with the use and enjoyment of nearby 	<ul style="list-style-type: none"> Subject to be discussed at Community Liaison Committee meetings.

		<p>residential properties on a permanent basis.</p> <ul style="list-style-type: none"> The Proponent will provide the telephone number of the on-site quarry office and document all complaints within a Complaints Log. All callers will receive a return phone call to ensure issues are documented and addressed. 	
5. Potential for siltation in the marine environment	<ul style="list-style-type: none"> Section 7.4 and Table 10-1. 	<ul style="list-style-type: none"> Total suspended solids in water released from the site will respect maximum values listed in the CCME Water Quality Guidelines for the Protection of Aquatic Life (Marine) and the Nova Scotia Pit and Quarry Guidelines. 	<ul style="list-style-type: none"> Surface Water Quality Monitoring Program
6. Introduction of invasive species through ballast water	<ul style="list-style-type: none"> Section 6.11.4 	<ul style="list-style-type: none"> Illegal ballast exchange is a criminal act. The Proponent will investigate and employ a reputable shipping firm for aggregate transport. 	<ul style="list-style-type: none"> Observations regarding shipping access to the marine terminal, including ballast water discharge will be discussed at the Community Liaison Committee meetings.
7. Radon monitoring	<ul style="list-style-type: none"> Radon is not expected to accumulate in the open air quarry 	<ul style="list-style-type: none"> The Proponent will respect all provisions in the provincial <i>Workplace Health and Safety Regulations</i> made under the Occupational Health and Safety Act. 	<ul style="list-style-type: none"> Radon monitoring will be undertaken if/when requested by NSE or other regulatory agency.
8. Changes to surface water quality and baseflow	<ul style="list-style-type: none"> Section 7.6 and Table 10-1. 	<ul style="list-style-type: none"> Surface water discharged from site will comply with quality criteria in the Pit and Quarry Guidelines, CCME Guidelines for suspended solids, and provisions in the operating permit. Changes in peak flow of water discharged from the site will not measurably increase the risk of flooding to downstream watercourses. Reductions to means annual runoff to off-site watercourses will not exceed 20%. 	<ul style="list-style-type: none"> Surface Water Quality Monitoring Program
9. Effective surface and groundwater management prior to discharge	<ul style="list-style-type: none"> Section 3.3.7 and Table 10-1. 	<ul style="list-style-type: none"> The Proponent will prepare a Stormwater Management Plan prior to construction. 	<ul style="list-style-type: none"> Surface Water Quality Monitoring Program
10. Management of archaeological resources including human remains	<ul style="list-style-type: none"> Section 7.16 and Table 10-1. 	<ul style="list-style-type: none"> The Proponent will prepare a Cultural Resources Management Plan prior to construction to guide response to any additional finds, including human remains. Area near Fogerty Head identified as having potential to contain human remains will be marked off to prevent future disturbance. 	<ul style="list-style-type: none"> Archaeological investigations will be undertaken to address 19th century building foundations identified on site. Report on the pre-construction archaeological investigation, including recommendations if applicable, will be made to the Nova Scotia Department of Communities, Culture and Heritage
11. Project effects on protected species	<ul style="list-style-type: none"> Section 7.12 and Table 10-1. 	<ul style="list-style-type: none"> Should Common Nighthawks initiate breeding activities on stockpiles or exposed areas on site despite efforts to deter them, the Proponent will establish a 20 m buffer around the location once identified, and contact CWS for further advice. Please see #12 for measures to address Mainland Moose. In the event of the mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds, EC-CWS will be notified within 24 hours. 	<ul style="list-style-type: none"> Mainland Moose Surveys will be performed annually for a period of three years after construction is initiated. Should Common Nighthawks initiate breeding, daily monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area. Inspection and other protective measures will be described within the Environmental Management Plan

12. Concern regarding wildlife, vegetation and wetlands loss	<ul style="list-style-type: none"> Section 7.7, 7.8 and 7.9 and Table 10-1. 	<ul style="list-style-type: none"> Mainland Moose studies would be performed annually for a period of three years after construction was initiated. A Wetland Compensation Plan will be developed in consultation with NSE. 	<ul style="list-style-type: none"> Mainland Moose survey methods would be based on NSDNR's Protocol for Mainland Moose Snow Tracking Survey and Pellet Group Inventory Data Collection Period. Survey transects and timing would be discussed with NSDNR prior to undertaking the work.
13. Effects of extreme weather	<ul style="list-style-type: none"> Section 8.6; Table 8-6 	<ul style="list-style-type: none"> At the detailed design phase the Proponent will again consider climate change, crustal subsidence and storm surge projections to inform marine terminal design. An Emergency Action Plan and Mooring Plan will be used to ensure appropriate measures are taken before and in reaction to severe weather events 	<ul style="list-style-type: none"> No follow up program is proposed
14. Effects on migratory birds	<ul style="list-style-type: none"> Section 7.3, Section 7.9; Table 10-1. 	<ul style="list-style-type: none"> In the event of the mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds, EC-CWS will be notified within 24 hours. Clearing activities will take place outside of the breeding season for most bird species (April 1 to September 1) to prevent the disturbance of migratory birds or their nests. If some clearing is necessary during the breeding season the feasibility of maintaining compliance with the <i>Migratory Birds Convention Act</i> will be assessed and a contingency plan developed in consultation with CWS 	<ul style="list-style-type: none"> Routine site monitoring as described in the Environmental Management Plan will include maintaining records of bird mortality so developing issues related to lighting can be identified. The Environmental Management Plan will include for ground- or burrow-nesting species. Should these species initiate breeding on stockpiles or exposed areas, periodic monitoring of the nest(s) will be undertaken until the chicks have fledged and left the area and the nest site is found to be inactive. EC-CWS will be consulted in order to verify the effectiveness of mitigation measures related to lighting, including implementation of the protocol "<i>Best practices for stranded birds encountered offshore Atlantic Canada</i>" (EC 2014e) for responding to avian strandings in the marine environment.
15. Traditional use of the land by Mi'kmaq people	<ul style="list-style-type: none"> These lands are not currently used for traditional resource harvesting. 	<ul style="list-style-type: none"> The site will remain available for traditional harvesting to the extent this is not precluded by safety considerations. 	<ul style="list-style-type: none"> Subject to be discussed at Community Liaison Meetings and directly with Mi'kmaq representatives
16. Effects on marine and coastal ecosystems	<ul style="list-style-type: none"> Sections 7.6, 7.11, 7.12, 7.15 and Table 10-1. 	<ul style="list-style-type: none"> Total suspended solids in water released from the site will respect maximum values listed in the CCME Water Quality Guidelines for the Protection of Aquatic Life (Marine) and the Nova Scotia Pit and Quarry Guidelines. A Fisheries Offset Program will be undertaken to restore habitat lost or damaged with the construction of the marine terminal 	<ul style="list-style-type: none"> Monitoring of the effectiveness of the marine Fisheries Offset Program would be undertaken for at least three years until it can be demonstrated that the program objectives have been met. Monitoring objectives and methodology will be established in consultation with DFO
17. Effects on marine life, fish; existing and	<ul style="list-style-type: none"> Sections 7.6, 7.11, 7.12, 	<ul style="list-style-type: none"> Avoid construction during lobster fishing season to the extent 	<ul style="list-style-type: none"> Monitoring of the effectiveness of the marine

emerging fisheries	7.15 and Table 10-1.	<p>possible.</p> <ul style="list-style-type: none"> • A Fisheries Offset Program will be undertaken to restore habitat lost or damaged with the construction of the marine terminal • A Marine Communication Strategy is proposed to help ensure efficient and timely communication between the Proponent and local fishermen. 	<p>Fisheries Offset Program would be undertaken for at least three years until it can be demonstrated that the program objectives have been met.</p> <ul style="list-style-type: none"> • Monitoring objectives and methodology will be established in consultation with DFO. • Terminal operations and fishing access will be monitored at the Community Liaison Committee meetings in response to concerns expressed by the local fishing community, as needed.
Socio-Economic Subjects			
1. Perceived effects of the quarry on property values	<ul style="list-style-type: none"> • Section 7.13; all mitigation measures in Table 10-1 are applied to reduce actual and perceived project impacts that may directly or indirectly affect property values. 	<ul style="list-style-type: none"> • The Proponent commits to the mitigation and monitoring measures presented in the EIS. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Meetings
2. Transparency/due process during expropriation	<ul style="list-style-type: none"> • Expropriation was undertaken by the MODG and is not part of the environmental assessment. 	<ul style="list-style-type: none"> • Not applicable 	<ul style="list-style-type: none"> • Not applicable
3. Commitment hire locally and employ union members	<ul style="list-style-type: none"> • Ongoing dialogue at the Community Liaison Committee meetings 	<ul style="list-style-type: none"> • The Proponent is committed to ongoing communication with labour unions and other labour sources with the aim of employing locally sourced, skilled workers, both union and non-union, to the extent they are available when needed at the site. • The Proponent has and will again in the future present skills requirements at local high schools and community colleges. • The Proponent will solicit and interview local workers for employment vacancies. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
4. Inflated job estimates / use of temporary foreign workers	<ul style="list-style-type: none"> • Ongoing dialogue at the Community Liaison Committee meetings 	<ul style="list-style-type: none"> • The Proponent reiterates job estimates presented in the EIS. • No temporary foreign workers will be used unless employment vacancies cannot be filled otherwise. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
5. Continued use of the site for trapping	<ul style="list-style-type: none"> • Safety restrictions may limit but not eliminate trapping on certain areas of the property at least in the near future. • Ongoing dialogue at the Community Liaison Committee meetings 	<ul style="list-style-type: none"> • The Proponent will endeavour to accommodate trapping to the extent that safety considerations are not compromised. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
6. Concern regarding changes to tourism	<ul style="list-style-type: none"> • Section 7.14 and Table 10-1 	<ul style="list-style-type: none"> • Ongoing dialogue at the Community Liaison Committee 	<ul style="list-style-type: none"> • Subject to be discussed at Community

and recreational land and water use patterns		meetings.	Liaison Meetings.
7. Concern regarding lack of local benefits	<ul style="list-style-type: none"> • Ongoing dialogue at the Community Liaison Committee meetings 	<ul style="list-style-type: none"> • The Proponent reiterates job estimates and local benefit calculations presented in the EIS. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
8. Potential for tax payer funded clean up upon closure	<ul style="list-style-type: none"> • Section 3.4 	<ul style="list-style-type: none"> • A Site Rehabilitation Plan is required by the Nova Scotia Pit and Quarry Guidelines. As part of the Plan, a security bond to pay for rehabilitation in the case of default is required. 	<ul style="list-style-type: none"> • No follow up is proposed.
9. Concern regarding physical appearance of quarry	<ul style="list-style-type: none"> • Section 3.1.1, Section 3.3.9 	<ul style="list-style-type: none"> • A 30 m wide wooded buffer will be left along the coastline. The quarry will not be visible from Marine Drive (Route 16). 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
10. Concern regarding the permanent change in land use	<ul style="list-style-type: none"> • Section 7.13, Table 10-1 	<ul style="list-style-type: none"> • Recreational users will be notified of restricted access by signage at the entrance to the construction site. 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings
11. Proponent commitment to sustainability and the community	<ul style="list-style-type: none"> • Not applicable 	<ul style="list-style-type: none"> • Proponent provided information regarding its community outreach programs and sustainability record. 	<ul style="list-style-type: none"> • No additional follow up is proposed.
Raised by the Mi'kmaq			
1. Employment/training opportunities; expectations regarding an impact benefits agreement	<ul style="list-style-type: none"> • The Proponent has commenced and will continue to engage Mi'kmaq communities in the planning and development process 	<ul style="list-style-type: none"> • Initiated communication with Chiefs and KMK; made commitments in a draft MOU pertaining to development of long-term relationship and provision of Project benefits. • The Proponent will monitor the progress and implementation of MOU and any other agreements to ensure that the Aboriginal community is able to participate and benefit from opportunities by the Project." • The Proponent will continue to make Project status presentations and offer site visits to interested Mi'kmaq representatives 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings. CLC membership includes Mi'kmaq representatives and is open to other interested Mi'kmaq.
2. Potential for petroglyphs or other Mi'kmaq historic cultural resources on the site	<ul style="list-style-type: none"> • Section 7.16 and Table 10-1. 	<ul style="list-style-type: none"> • Two archaeological studies undertaken; no evidence in Mi'kmaq historic cultural resources was found. • Culture Resource Management Plan to be prepared before construction begins. • The Proponent has committed to a separate site visit undertaken with a qualified Mi'kmaq archaeologist prior to project implementation. 	<ul style="list-style-type: none"> • Archaeological investigations will be undertaken to address 19th century building foundations identified on site. • Report on the pre-construction archaeological investigation, including recommendations if applicable, will be made to the Nova Scotia Department of Communities, Culture and Heritage • Subject to be discussed at Community Liaison Committee Meetings. CLC membership includes Mi'kmaq representatives and is open to other interested Mi'kmaq.
3. Potential Effects on Mi'kmaq commercial, recreational and Food/Social/Ceremonial fisheries	<ul style="list-style-type: none"> • Section 7.15 and 7.17; Table 10-1. • No current commercial, recreational or FSC resource use was identified. 	<ul style="list-style-type: none"> • The Proponent is committed to continuing discussion and collaboration on these subjects, ideally through Mi'kmaq participate in the Community Liaison Committee. • The Proponent will continue to make Project status presentations and offer site visits to interested Mi'kmaq 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings. 5. Concerns for fish, fish habitat, and Mi'kmaq fisheries	<ul style="list-style-type: none"> • Section 7.11, 7.15 and 7.17; Table 10-1. • Mi'kmaq representatives have been invited to participate as members in the Community Liaison Committee. 	<ul style="list-style-type: none"> • Mi'kmaq Ecological Knowledge Study undertaken • The Proponent's dialogue with Mi'kmaq communities has addressed potential project-related effects and establishes commitments for effects management and communication. • The Proponent will continue to make Project status presentations and offer site visits to interested Mi'kmaq representatives 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings. CLC membership includes Mi'kmaq representatives and is open to other interested Mi'kmaq.
6. Consultation and Engagement	<ul style="list-style-type: none"> • The Proponent has engaged the Mi'kmaq since February, 2014. This engagement is ongoing. • Mi'kmaq representatives have been invited to participate as members in the Community Liaison Committee. 	<ul style="list-style-type: none"> • Direct dialogue with Mi'kmaq organizations and communities without prejudice will be maintained. • The Proponent will continue to make Project status presentations and offer site visits to interested Mi'kmaq representatives 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings. CLC membership includes Mi'kmaq representatives and is open to other interested Mi'kmaq.
7. Project effects on biophysical attributes listed above	<ul style="list-style-type: none"> • Please see Biophysical sections above 	<ul style="list-style-type: none"> • Please see Biophysical sections above 	<ul style="list-style-type: none"> • Please see Biophysical sections above
8. Changes to current use of land and resources by the Mi'kmaq for traditional purposes	<ul style="list-style-type: none"> • No current traditional resource use was identified. 	<ul style="list-style-type: none"> • The Proponent commits to allowing future access to non-active portions of the site to the extent this does not compromise the safety of the Mi'kmaq visitors or quarry workers. • The Proponent will continue to make Project status presentations and offer site visits to interested Mi'kmaq representatives 	<ul style="list-style-type: none"> • Subject to be discussed at Community Liaison Committee Meetings. CLC membership includes Mi'kmaq representatives and is open to other interested Mi'kmaq.

11.0 CONSULTATION AND ENGAGEMENT

11.1 Consultation Strategy and Objectives

The Proponent has developed and implemented a public consultation program that engages stakeholders and satisfies the requirements of the Nova Scotia *Environmental Assessment Regulations* and the Proponent's Guide to Environmental Assessment (NSE 2009). The Proponent has been and remains committed to open and transparent engagement using an approach that fosters collaborative working relationships. The Proponent strives to be the best source of information for stakeholders about the Project.

As part of Project development, the Proponent implemented a comprehensive consultation program with the following key objectives:

- to identify issues and concerns of interest to the affected communities, stakeholder groups and residents;
- to assist in judging the nature and intensity of Project benefits or impacts;
- to solicit local information and expert opinions; and
- to fulfil regulatory requirements.

The consultation program is intended to continue throughout the Project development process. It started in the early planning stages of the Project in 2010, expanded during the formal environmental assessment process, and is scheduled to continue through subsequent approvals, permitting and construction phases. The Proponent also intends to continually engage with all stakeholders during the operation of the facility. A full list of consultation and outreach events is provided in **Appendix M**, Attachment 4.

11.2 Public and Agency Consultation

The Proponent, using a variety of public outreach methods, has informed stakeholders of the Project, explained the planning and regulatory processes, advertised consultation and engagement opportunities and solicited input into the Project Description and the EIS report.

Specific engagement tools and techniques that have been applied during the public consultation program include:

1. a Project-specific website – www.blackpointquarry.ca
2. a stakeholder database including email and mailing lists used for email outreach to interested residents and others;
3. an open house event, public information sessions, and public presentations;
4. public notices regarding key milestones and CLC membership;
5. interviews with provincial and local media outlets;
6. a Project newsletter distributed via mail drops, newspaper inserts and email;
7. the Community Liaison Committee (CLC);
8. government agency briefings (federal, provincial and local); and
9. other stakeholder group meetings and door-to-door introductions to residents.

These items are described in greater detail below.

11.3 Website

A Project website was established early in assessment process, when the Project Description was first being elaborated in February, 2014. The website was created to allow the public easy access to up-to-date information about the Project. The website also functions as the authoritative source of information for all stakeholders. The website address is www.blackpointquarry.ca. The website includes:

- Project overview
- Project history
- Project details:
 - Location
 - Aggregate Market
 - Project Benefits
 - Project Decommissioning
 - Maps and Photographs
- Community information
 - Community Liaison Committee
 - Questions and Answers
 - Frequently Asked Questions
 - Newsletters
 - Presentations
 - Reports

The Project website also includes a link to the CEA Agency website. The Project website will continue to be updated as the Project moves through the environmental assessment process.

11.4 Stakeholder Database and Mailing List

A stakeholder database was created at the beginning of the Project. During the first open house held on April 22, 2014, visitors were invited to provide their name and contact information (mailing address, telephone and email address) to receive updates on the Project. Since that time, the team has continued to add names of interested people to the Project stakeholder database.

A designated Project team member is tasked with maintaining the database and mailing list. There are currently 240 names on the list. The stakeholders in the database have been identified and grouped according to their interest as they relate to the Project (Table 11-1).

Table 11-1: Stakeholder Database and Mailing List Categories

Interest Group Category		
Open House Attendees	Mi'kmaq	Elected Officials
CLC Members	Local Fisherman	Government - Federal
Local Residents	Guysborough Inshore Fisheries Association	Government - Provincial
Non-Government Organizations	Media	Businesses

Updates regarding activities associated with the Project (meetings, field studies, reports) are circulated regularly; to date, eight outreach communications have been provided to people and organizations on the mailing list (Table 11-2).

Table 11-2: Stakeholder Outreach Communications

Date	Item	Distribution Method	Approximate Total Distribution
April-09-14	Open House Announcement	Ad in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses
April-14-14	Morien Press Release re: Vulcan and the Project	Newswire / Press Release	>900 Canadian news outlets
April-17-14	Open House Announcement	Canada Post Mail Drop	3,000 households; does not incl farms, business, apartments
April-22-14	Display Boards, Vulcan Presentation Booklets	Hand-outs at the Open House	200+ attendees
April-30-14	CLC Member Solicitation	Ad in the Guysborough Journal	1,200 people; newsstands, subscribers, businesses

February 4-15	Winter 2015 Newsletter	Canada Post Mail Drop	3,000 households not including farms, business, apartments

11.5 Public Information Sessions/Open Houses

The first Open House was held at the Queensport Fire Hall in Guysborough on April 22, 2014. The goal of the Open House was to inform the community about the Black Point Project and the environmental assessment process, and describe anticipated Project timelines. The Open House provided an opportunity for citizens to engage directly with the Proponent's Project team, which included specialists in Health and Safety, Engineering Design, Geology, Environmental Assessment, Quarry Operations and Communication. Two different information sessions (afternoon and evening) were held to accommodate interested visitors. Over 200 people attended the two sessions.

The format was casual, allowing visitors to meet the individual Project team members, ask questions, and voice concerns. With over 21 large format information boards on display, Project team members and subject matter experts were on hand to talk about the Project and answer questions. The topics of the information boards are provided in Table 11-3.

Table 11-3: Open House Information Display Topics

Display Board Topics		
Vulcan Materials Company	Marine Terminal	Federal EA Process
Morien Resources Corp.	Aggregates Explained	Existing Environment
Black Point Quarry	Aggregates Market	Safety
Maps – Project Location	Project Benefits	Land Management
Aggregates Mining Process	Project Schedule	Environmental Stewardship
Production Plan	Information & Engagement	Geology

At the Open House, visitors were asked to sign-in and provided an opportunity to sign-up for future updates on the Project. At one information display board and table, visitors were invited to volunteer to serve of the Project Community Liaison Committee (CLC). During the Open House, comment cards were made available to visitors for future follow-up with the Project team.

In May 2014, a follow-up email was circulated to those who provided their email address requesting confirmation of their interest in receiving updates on the Project as required by the new "anti-spam" legislation, which came into force in early 2014. Project team members continue to meet with stakeholders individually or in groups to provide updates on the Project and answer questions.

An additional Open House has been tentatively scheduled for mid March, 2015, once the EIS report has been submitted and the prescribed comment period is underway.

Additionally, several presentations have been given to various groups interested in the Project. These community presentations are provided in Table 11-4.

Table 11-4: Community Presentations

Presentation Topic	Group	Date
Black Point Marine Aggregate Quarry Update	Mining Society of Nova Scotia	June 6, 2014
Introduction to Vulcan Materials and the Project	Strait of Canso Superport Days	July 10, 2014
Project Introduction and Jobs in the Mining Industry	Fanning Academy, grades 9-12	October 16, 2014
Geology Presentation	Fanning Academy, 4th grade	October 16, 2014
Project Introduction and Jobs in the Mining Industry	Guysborough Academy, grades 9-12	October 28, 2014
Geology Presentation	Guysborough Academy, Middle School	October 28, 2014
Introduction to Vulcan Materials and the Project	Geology Matters Conference, NS Department of Natural Resources	November 13, 2014
Introduction to Vulcan Materials and the Project	Strait Area Chamber of Commerce	December 2, 2014

11.6 Interviews

The Proponent has been asked by several media outlets to provide comment or updates on the Project. Table 11-5 lists the interviews conducted to date.

Table 11-5: Media Interviews

Interview Topic	Media Outlet	Date

Interview, GCIFA endorsement	Chronicle Herald	January 13, 2015
Interview, GCIFA endorsement	Port Hawkesbury Reporter	January 15, 2015

11.7 Newsletters

The Proponent has developed the Black Point Quarry Project Newsletter to provide updates on the Project and to keep interested parties informed about the progress and current/upcoming activities. The first issue of the Black Point Quarry Project newsletter was distributed on July 30, 2014. Referred to as the Summer 2014 Newsletter, the information sheet was emailed to the Project stakeholder database and mailing list, and was distributed by Canada Post that

same week to residents in Guysborough County. A copy of this issue and all future issues will be available on the Project website.

This inaugural issue announced the beginning of the environmental assessment, provided an anticipated timeline for the assessment and project overview, and described the open house, the Superport Days event and the formation of CLC. Future newsletters will continue to provide readers with important information about the project and key milestones.

The newsletter will be distributed to stakeholders on a semi-annual basis, or when specific project developments warrant an additional newsletter. Copies of the Summer 2014 and Winter 2015 newsletters are included in **Appendix M Attachment 1**.

11.8 Community Liaison Committee

In mid-2014, the Proponent established a CLC to help document community questions and concerns and distribute updates regarding the Project. The overarching objectives of the CLC are:

- to facilitate frank and open communication between the local community and the project team; and
- to provide a forum for the two way exchange of accurate and up-to-date information between the community and the Proponent.

The ultimate, long term objective of establishing the CLC is to protect and enhance the quality of life for all residents and to promote a vibrant and sustainable economic climate in the Municipality of the District of Guysborough.

The Proponent solicited CLC membership at the first Open House in April, 2014 and through a public notice published in the Guysborough Journal. Twenty volunteers expressed interest in participating in the CLC. From that list, eight community members were selected to serve with four Project Team members. The CLC members represent the following communities or groups (Table 11-6):

Table 11-6: CLC Communities and Groups Represented

Canso	The Sipekne'katik Band (formerly the Shubenacadie Band)
Cook's Cove	Antigonish/Guysborough Black Development Association
Phillips Harbour	Director of Economic Development, MODG
Fox Island	District 4 Councillor, MODG
Guysborough	Vulcan Materials Company
Queensport	Morien Resources Corp.

The first CLC meeting was held on August 12, 2014 at the Queensport Fire Hall. Two Co-Chairs were nominated to lead the CLC: Mary Jurgina-Taylor (Canso resident) and Chris Ridgway (Vulcan Materials Company). Atisthan Roach (Vulcan Materials Company) is currently serving as secretary for the CLC.

During the first meeting, the CLC discussed their Terms of Reference (TOR) and frequency of meetings. The TOR was agreed upon, and CLC meetings were determined to take place quarterly, or when specific project developments warrant. The second CLC meeting was held on October 15, 2014 at the Queensport Fire Hall. The next CLC meeting is tentatively scheduled for mid-March, 2015.

A copy of the TOR is included in **Appendix M Attachment 2**.

11.9 Government and Agency Consultation

The Black Point Quarry Project team has been consulting with government officials and regulators (municipal, provincial, and federal), both formally and informally, on an ongoing basis. The objective of these consultations is to provide information and updates on the Project and the environmental assessment, and also to receive input and guidance as appropriate. The CEA Agency and the following federal Regulatory Authorities have been consulted both before and since filing of the Project Description:

- CEA Agency
- Transport Canada (TC)
- Fisheries and Oceans Canada (DFO)
- Environment Canada (EC)
- Natural Resources Canada (NRCan)
- Health Canada (HC)

There have also been on-going meetings with the provincial Department of Environment and the Department of Natural Resources to keep them apprised of Project developments and solicit input into study design.

These consultations have involved one-on-one meetings, telephone conversations, and e-mail correspondence. Issues and concerns identified during these meetings are presented in greater detail within the EIS.

11.10 Other Group Meetings

Please see **Appendix M**, Attachment 4 for a full list of consultation and outreach events.

Guysborough County Inshore Fishermen's Association

The Guysborough County Inshore Fishermen's Association (GCIFA) is considered a key local and regional stakeholder group with direct and ongoing interest in the Project. Given this, a series of meetings and information exchanges were held with GCIFA representatives to learn about fishermen and fishing activity in the area and to provide information regarding the Project to the GCIFA. The GCIFA was extremely helpful in putting Project team members in touch with local fishermen, and in facilitating meetings by offering meeting space and communicating meeting opportunities to fishermen. Although the GCIFA provided useful information to the Project team, their representatives underlined the fact that the fishermen "speak for themselves", rather than exclusively through the Association.

Concerns expressed and issues raised by the GCIFA and local fishermen are summarized in Table 11-7.

Meetings with Fishermen

Based on information provided at the April Open House and with the help of the GCIFA and local residents, the Project Team compiled a list of fishermen most likely to be interested in the Project and its potential effects on commercial fishing. Sit down meetings with local fishermen were held on several occasions as summarized in Table 11-6. The overall objective of the meetings was to meet the fishermen, introduce the Project and some of its team members, and discuss / document questions and concerns with respect to commercial fishing. The meetings were intended to initiate a dialogue with fishermen that will continue as more information becomes available with respect to Project design, layout and day to day activities at the site. The ultimate objective was to identify fishermen concerns so they could be addressed within the EIS report.

Table 11-7: Issues and Concerns Raised by People in the Commercial Fishing Industry

People in the Commercial Fishing Industry				
Event	Date	Comment Source	Made To	Comment, Question or Concern
Letter to CEAA	24-Mar-14	Thomas Grover WT Grover Fisheries Ltd.	CEAA	<ul style="list-style-type: none"> • Supportive of the Project.
Letter to CEAA	27-Mar-14	Eugene O'Leary, President Guysborough County Inshore Fishermen's Association	CEAA	<ul style="list-style-type: none"> • Requests additional consultation. • Notes Project Description inaccurately describes local fishing conditions. • Expresses concerns regarding displacement of fishermen, silting and noise. • Supportive of project but not at the cost of the fishing industry.
Meeting	8-Apr-14	Ginny Boudreau, Manager Guysborough County Inshore Fishermen's Association	Proponent	<ul style="list-style-type: none"> • Concerns expressed regarding potential impacts to lobster, shrimp, and ground fisheries. • Concern raised regarding increased traffic and displacement from fishing grounds around shipping lanes. • Concerns expressed regarding potential shipping impacts to shrimping activities. • Tentatively supportive of the Project. • Questioned the setback distance from the terminal (where no fishing will be permitted). • Concerns expressed regarding the effects of blasting on fish – mainly lobster. • Questioned the effects of siltation runoff on lobster fishing. • Questioned if the Proponent will offer training courses to local workers. • Questioned if "foreign workers" will be used at low wages instead of local workers.
Letter	14-May-14	William Bond, Fisherman	CEAA re Draft Guidelines	<ul style="list-style-type: none"> • Concerns expressed regarding the guidelines: <ul style="list-style-type: none"> ○ lack of detail regarding the marine environment ○ fisher compensation ○ monitoring of environmental effects ○ biomass of aquatic species as baseline information ○ impacts to marine waterfowl migration patterns ○ baseline data regarding invasive species (zebra mussels and green crab) ○ monitoring and company mitigation should new invasive species be discovered ○ effects of silt run off ○ effects of severe weather on project infrastructure.
Meeting	29-May-14	Ginny Boudreau, Manager Guysborough County Inshore Fishermen's Association	Proponent	<ul style="list-style-type: none"> • Concerns expressed regarding: <ul style="list-style-type: none"> ○ increased traffic and the location of increased traffic ○ new buoy/markers ○ how ships will affect existing fisheries as they leave the shipping lane ○ siltation

People in the Commercial Fishing Industry

Event	Date	Comment Source	Made To	Comment, Question or Concern
Meeting	16-Jul-14	David Murphy, Fisherman	Proponent	<ul style="list-style-type: none"> Concern expressed that the Project will not consult with other fishers who are permitted to fish within LFA 31a.
Meeting	16-Jul-14	Jerry Creamer, Fisherman	Proponent	<ul style="list-style-type: none"> Concerns expressed regarding: <ul style="list-style-type: none"> coal dust from ongoing transfer operations invasive species in ballast water potential displacement of shrimp and scallop fishermen
Meetings	17-Jul-14	Fishermen: Kenny Snow, Alan Newel, Bob Anderson, Tom Anderson, Steve Mead, Billy Bond, Basil Dobson, Ben Hensbee, Dave Murphy, Allan Hensbee, Thane Jameson	Proponent	<ul style="list-style-type: none"> Questioned if dust from off-loading will cause siltation on nearby lobster beds. Questioned the amount of silt that will be discharged (in storm water or process water) and how far the tides and currents will disperse the silt. Questioned the effect of ships leaving the shipping lane to access the marine terminal on shrimp and scallop fishers. Questioned the amount of lobster fishing grounds to be lost. Questioned the size of the exclusion zone or "off limits zone". Questioned the cumulative traffic effects of additional ships combined with new ships when the new container terminal starts up. Concerns expressed regarding the effects on fishing from additional noise, displacement of fishers and loss of gear. Questioned how ballast water from ships will be addressed. Questioned the management of new invasive species from ballast water. Questioned the cumulative effects of new invasive species from ballast water (two years from now, five years, ten years). Questioned the effect of blasting and vibration on lobster and if blasting will push them offshore. Questioned if blasting will cause the female lobster or snow crab (or other egg carriers) to drop their eggs early. Questioned the assurances or guarantees that can be given that the Project will not destroy the Bay or their livelihood with explosives by scaring away or changing the behaviour of these species. Concerns expressed regarding mackerel and squid being diverted by noise and vibrations from blasting. Concerns expressed regarding the displacement of fishers onto other fishers as the area is reportedly fully fished with little room for displacement. Questioned if the shipping lane can skirt a depression off of Black Point that extends for several kilometres, as it has a muddy bottom and is very good for shrimp fishery, and come parallel to the shoreline to avoid the prolific shrimp grounds.
Meeting	13-Aug-14	Fishermen: Garth Meade, Jim Meade	Proponent	<ul style="list-style-type: none"> Appreciative of Proponent's efforts to meet with them. Questioned if the dates and times of ship arrival and departures could be posted.

People in the Commercial Fishing Industry

Event	Date	Comment Source	Made To	Comment, Question or Concern
Meeting	15-Oct-14	Fishermen: Kevin Horne, Howard Jack, Alan Newel, Bob Anderson, Basil Dobson, Allan Hensbee; Others: Eugene O'Leary, Ginny Boudreau, Sara Delory (GCIFA)	Proponent	<ul style="list-style-type: none"> • Discussion of proposed shipping routes; one preferred route was selected by the fishermen present • Discussion of the marine terminal and probable exclusion zone; • Discussion of nearby areas suitable for the creation of new lobster habitat • Discussion of mackerel behaviour with respect to A. Newell's traps in Indian Cove – will the terminal interrupt their movement along the shore? • Discussed training requirements for workers at the quarry • Discussion of sedimentation, effects of blasting, bilge water disposal
Meeting	12-Jan-15	Eugene O'Leary, Ginny Boudreau, William Bond, Roger Williams, Patricia Rhynold, Duncan Bellefontaine	Proponent	<ul style="list-style-type: none"> • Update on the Project • Letter of endorsement from the GCIFA

Door to Door Meetings

Although many residents attended the first Open House in April, 2014, the Proponent was not entirely sure that all of residents nearest to the Project site were able to attend that event. To help ensure these residents had the opportunity to learn about the Project, pose questions, express concerns, and contact the Project team specialists if needed in the future, two Project team members (Mike MacDonald, Morien Resources and Russell Dmytriw, SLR Consulting) went door-to-door along Half Island Cove Road, Upper Fox Island and Fox Island Main during the week of July 14, 2014. In total, 17 of 25 addresses were visited and face-to-face meetings held. Of the 8 unvisited residences, 4 occupants were not home while 4 addresses were not occupied (i.e., for sale or apparently abandoned).

Residents typically expressed support for the Project, especially with respect to job opportunities for local residents and their children. At the same time, a certain degree of frustration was expressed at the perceived slow pace of development. Other residents were neutral or indifferent, neither positive nor negative towards the proposed Project. In several instances, discussions were more detailed; certain residents posed a number of questions regarding project effects to the local environment, water quality, ambient noise conditions and other subjects. Project team members responded to questions and followed up with additional information by email where needed. In all cases, residents who expressed concerns were open minded and interested in learning more about the Project. Concerns expressed and issues raised by local residents are summarized in Table 11-8.

Other concerns and questions have been raised during Proponent outreach events by people who are not residents of the immediate vicinity of the Project. These events and the subjects discussed are presented in **Appendix M Attachment 4**.

Table 11-8: Issues and Concerns Raised by Residents in the Project Vicinity

Residents in the Project Vicinity (Names omitted to ensure privacy)

Meeting	17-Jul-14	Local Business (1 person)	Proponent	<ul style="list-style-type: none"> • Concerns expressed regarding noise generated at the quarry. • Concerns expressed regarding the effect on her well water.
Email	31-Jul-14	Residence #12 (2 people)	Proponent	<ul style="list-style-type: none"> • Thanked the Proponent for the update.

11.11 Engagement of Aboriginal Communities

11.12 Strategy and Objectives

The Proponent understands that it is the duty and responsibility of the Crown to consult with First Nations regarding matters related to the impact development projects may have on the Treaty and Aboriginal Rights of the Mi'kmaq, and that these responsibilities are met through direct consultations between the Nova Scotia Office of Aboriginal Affairs and the Kwi'mu'kw Maw-Klusuaqn (KMK) Negotiations Office. The Proponent is also cognizant that there are several international, national, and provincial protocols and procedures that aim to advance First Nation involvement in environmental management and promote cooperation between project proponents and Aboriginal communities in Nova Scotia. As a result, the Proponent has undertaken several measures to identify the concerns of Mi'kmaq communities, through their designated representatives, about potential adverse effects or the environmental effects of the Project, and to promote Mi'kmaq involvement in the Project. Similar to other development initiatives in Nova Scotia, The Proponent has taken direction from "A Proponent's Guide to Environmental Assessment," and "Proponents' Guide: Engagement with Mi'kmaq of Nova Scotia," in developing its strategies and objectives (NSE 2014; NSOAA 2009).

The Proponent has also taken a more proactive approach by following the principles of Free, Prior and Informed Consent as presented and discussed within the United Nations Permanent Forum on Indigenous Issues. To this end, the Proponent has addressed early engagement with the Mi'kmaq community in Nova Scotia as a priority and has developed an Aboriginal Community Engagement Strategy, which commenced several years prior to the filing of the Project Description with in February 2014. The premise of the engagement strategy is that, through effective engagement, the Proponent can establish an effective relationship with Mi'kmaq communities and organizations. The Proponent's objectives were to:

- inform Mi'kmaq communities about its proposal;
- solicit information on the Mi'kmaq issues and concerns with respect to the proposed Project; and
- identify ways and means for Mi'kmaq engagement in the planning process and approaches to a mutually beneficial Project implementation.

Based upon a preliminary assessment of the Project location and the known activity of Mi'kmaq communities in Nova Scotia, several communities and Mi'kmaq organizations were identified as potentially affected and/or having a direct interest in the Black Point Quarry Project. These communities (shown on **Figure 6.8-1**) and organizations are listed in Table 11-9.

Table 11-9: Key Mi'kmaq Communities

Category	Communities/Organizations
Mi'kmaq communities	Paqtnkek First Nation
	Potlotek First Nation
	Millbrook First Nation
	Sipekne'katik First Nation
Mi'kmaq organizations	Assembly of NS Mi'kmaq Chiefs Kwilmu'kw Maw-Klusuaqn
	(KMK) Negotiations Office
	KMK Benefits Committee
	Sipekne'katik Negotiations Office
Provincial organizations	Nova Scotia Office of Aboriginal Affairs

11.13 Engagement Strategy and Activities

As noted above, the primary objectives of the Mi'kmaq engagement strategy are to establish a positive collaborative working relationship with the Mi'kmaq of Nova Scotia, and to identify potential issues of concern to the Mi'kmaq communities or their representatives that could potentially cause negative effects on the Mi'kmaq if not addressed. To achieve these objectives, The Mi'kmaq Community Engagement Strategy for the Black Point Quarry Project involves a series of engagement activities that include:

- face to face contacts with Chiefs and Council representatives;
- presentations/meetings with communities;
- presentation at regional Tribal Council/Provincial Tribal Organization meetings;
- frequent telephone and email communication;
- letters of notification of EA;
- MEK Study;
- tours of the Project site on three occasions; and
- telephone interviews with Band Fishery Managers with members holding communal commercial licenses in the area.

The engagement activities that have taken place to date are listed in Table 11-10. In addition invitations to all Public meetings/Open House events (Section 11-3) were sent to representatives of the Mi'kmaq communities identified in Table 11-9 above.

Table 11-10: Engagement Activities

Mi'kmaq Community Engagement Activities	Date
Face to Face Contacts with Chiefs	
Paqtnekek	Oct 12, 2010 (initial meeting with Chief)
Millbrook	Mar 21, 2011 (initial meeting with Band Manager)
	May 7, 2014
Sipekne'katik	Jun 18, 2014
	Aug 12, 2014 (site visit)
Presentations / Meetings with Communities	
Sipekne'katik Band Council	Jun 17, 2014
	Aug 11, 2014
	Aug 12, 2014 (site visit)
Presentation at regional Tribal Council/Provincial Tribal Organization Meetings	
	Oct 13, 2011 (initial meeting with CEAA)
	Nov 21, 2011
KMK staff	Sept 20, 2013 (with CEAA)
	Mar 11, 2014
	May 27, 2014
	Jun 18, 2014 (site Visit)
KMK - Benefits Committee	Sep 10, 2014
Assembly of NS Chiefs	Through KMK
Site Visits	
J. Walsh, M. Nevin	18 June, 2014
J. Copage, I. Knockwood, J. MacDonald	August 12, 2014
Chief W. Marshall, K. Prosper	October 27, 2014

Finally, the Proponent has requested to present the Environmental Impact Statement report to the Assembly of Nova Scotia Chiefs and agreed to set up a web-based portal through which Mi'kmaq Communities can provide direct comment on the documents.

The Guidelines for the EIS were issued on June 9, 2014 (CEA Agency 2014). The Kwilmu'kw Maw-klusuaqn Negotiation Office provided comments which were forwarded to the Proponent for review and response, where applicable. The comments are presented in summarized form in Table 11-11.

Table 11-11: Key Comments and Issues Raised by Mi'kmaq Communities

Subject Area	Comments/Concerns/ Suggestions	Study Team Responses/Actions
Opportunities (Economics, Training, Other)	Seeking engagement in accordance with Proponents Guidelines, issued by the NS Government	Initiated communication with Chiefs and KMK; made commitments in a draft MOU pertaining to development of long-term relationship and provision of Project benefits.
	Potential for collaboration and employment	Negotiation of collaborative benefits agreement.
	Potential for training and skills development	Including training in negotiation of benefits agreement.
	Potential for support for KMK operations	MOU includes negotiation of support to facilitate development of benefits agreement.
Planning Process	MEK Study	MEKS updated and submitted for review.
	Environmental protection	Providing opportunity for direct review of the EA document (made presentation and provide means to facilitate

Subject Area	Comments/Concerns/ Suggestions	Study Team Responses/Actions
Review of EIS Guidelines/KMK meetings	Request internal review of MEKS	feedback). Agree. A copy of the MEKS has been provided for review and comment.
	Concerns for fish, fish habitat, and Mi'kmaq fisheries	A MEKS has been prepared as part of the EA process. This includes a discussion of potential effects on fishing. The Proponent's engagement program with Mi'kmaq communities has addressed potential project-related effects and establishes commitments for effects management and communication.
	Identified concerns for archaeological assessment	A MEKS and archaeological assessments have been prepared as part of the EA process. This includes a discussion of potential effects on archaeological sites. The Proponent's engagement program with Mi'kmaq communities also addresses potential project-related effects and establishes commitments for archaeological fieldwork and documentation. In addition the Proponent has committed to a separate site visit being undertaken with a qualified Mi'kmaq archaeologist prior to project implementation
	Kwilmu'kw Maw-klusuaqn Negotiation Office may coordinate Mi'kmaq representation in CLC.	The Proponent has established a CLC and invited Mi'kmaq community to be represented (Sipenkne'katik is represented).
	Identified expectations for impact benefits agreement.	The Proponent has commenced and will continue to engage Mi'kmaq communities in the Project's planning and development process. As such The Proponent is in the process of negotiating with the Kwilmu'kw Maw-klusuaqn Negotiation Office a comprehensive Cooperation Agreement.
Consultation and Engagement	Crown responsibilities and activities regarding consultation with Mi'kmaq communities about the Project.	Maintaining direct dialogue with Mi'kmaq organizations and communities without prejudice. Maintaining arm's length discussions with Office of Mi'kmaq Affairs.
	Distinction between Crown Consultation and Proponent Engagement.	Proponent is ensuring Project staff is not directly involved in negotiations between NS Government and Mi'kmaq negotiators.

11.14 Identified Issues and Concerns

As described above, preliminary meetings with the KMK Benefits Committee, and the Sipekne'katik Band Council, have been held. Presentation materials used during these initial contacts are provided in **Appendix M Attachment 3** while issues and concerns identified are summarized above in Table 11-11. Based on discussion during these engagement sessions, there is a general understanding between The Proponent and Mi'kmaq communities that the engagement process will continue to facilitate open dialogue on matters related to First Nations interest regarding environment and economic development.

11.15 Memorandum of Understanding (MOU)

The Proponent is in negotiations to conclude a MOU with the Assembly of Nova Scotia Chiefs through the KMK Benefits office and a separate MOU is being negotiated with the Sipekne'katik First Nation. The purpose and focus of these MOUs is to guide ongoing discussions regarding

collaborative benefits agreements (CBAs) between the Proponent and Mi'kmaq communities. Discussions have been ongoing since spring, 2014 and are proceeding in an open and constructive manner.

11.16 Engagement Following EIS Submission

The Proponent has committed to an ongoing relationship with the Mi'kmaq of Nova Scotia. In accordance with the terms of the MOU, the focus of engagement activities in the short-term will be the conclusion of the CBA. This Agreement will provide the foundation for continued engagement activities that will meet the spirit and intent of the MOU, namely, to cooperate with each other with respect to the Project on the basis of equality, reciprocity and mutual benefit. Future engagement activities will be coordinated through specifically designated contact persons, and through the Mi'kmaq Representatives on the Community Liaison Committee (CLC).

The Proponent will make presentations to update the Assembly of NS Chiefs, or their designated committees, on the Project from time to time. Mi'kmaq communities are also represented on the CLC and as such will be regularly involved in the discussion of Project planning and implementation with The Proponent and other community representatives.

The Proponent has also reserved seats on the Community Liaison Committee for representatives from both the KMK and the Sipekne'katik First Nation. This participation is expected to foster greater participation in the project both through bilateral processes under the CBA, and through community level activities in collaboration with participants from the community of Guysborough.

11.17 Issues Identified by Other Stakeholders

The Proponent has communicated with members of the public and stakeholders to provide updates on the Project and receive feedback regarding key issues or concerns. As described above the Proponent has met with individuals and groups to better understand issues and information to be considered during the environmental assessment. Contacts have been made either as face-to-face meetings, telephone conversations, and email correspondence. Key outreach events (meetings, telephone calls, emails, etc.) are provided in **Appendix M Attachment 4**. A summary of key comments and concerns is provided in Table 11-12.

11.18 Consultation Following EIS Submission

The Proponent will continue both public and agency consultations throughout the permitting, construction, and operation phases of the Project. Public consultation activities will include the continuation of the CLC, publication of newsletters, and as appropriate, public meetings. Agency consultation activities will focus on implementation of the conditions of environmental assessment approval, as well as requirements for federal, provincial, and local permits. Interactions and results of discussions with the regulatory agencies will be communicated to the public using the Project newsletter as warranted.

12.0 ENVIRONMENTAL IMPACT STATEMENT CONCLUSIONS

This section summarizes in Table 12-1 the environmental effects assessment presented in this EIS and presents the Proponent's concluding statements with respect to the Project's impacts on the environment and the environment's impacts on the Project.

12.1 Effects of the Project on the Environment

Project effects on the environment were assessed from the probable Project-environment interactions derived for each VC of interest to the different stakeholder groups identified for the Project. The assessment considered the nature of infrastructure required to support the quarry and marine terminal, as well as the activities that will be undertaken during the construction, operation and decommissioning phases of the Project. To the extent possible unforeseen incidents, malfunctions and accidental events were also considered as part of the assessment.

Three types of mitigation measures were applied to reduce or eliminate potential Project-environment interactions:

1. Design measures specifically applied to Project infrastructure before construction;
2. Standard, proven industry best management practices for industrial construction and operation in the marine and terrestrial environments; and
3. Site specific oversight, training, control, management and operational mitigation measures.

Following the application of these mitigation measures, residual effects were listed and assessed.

The significance of the residual effects (i.e., those that remain following mitigation) was determined by a commonly used environmental assessment methodology. All residual effects are assessed as not significant, that is, while residual effects are expected, no significant residual effects are predicted. As a result, the Project is not likely to have significant adverse effects on the environment over the short or long terms. A series of monitoring programs are proposed to verify these predictions, meet commitments made in the EIS, comply with regulatory requirements, and help identify unexpected effects that may arise in the future.

In contrast, the Project is predicted to have positive local and regional economic effects in the form of direct and indirect employment opportunities, increased discretionary income in the local economy, royalties paid for extraction of the granite resource and increased tax revenues to various levels of government. A corollary positive benefit results from the increased understanding of the evolving environmental conditions, including the use of the local area by Mainland Moose, that will result from Project-related commitments made as part of the assessment process.

Table 12-1 summarizes the expected effects of the Project, lists the criteria used to determine if an effect is "significant" and describes the mitigation measures for each VC. As the table notes, none of these effects is significant according to the criteria established for their assessment.

12.2 Effects of the Environment on the Project

As required by the EIS Guidelines issued by the CEA Agency and NSE for this Project, the potential effects of the environment on the Project were also evaluated.

The Black Point Quarry will utilize simple, robustly built and commonly employed industrial machinery that is currently found in many different coastal environments around the world. Quarry operations in Nova Scotia do not require unusually specialized equipment or operational procedures. Site equipment including the marine terminal will naturally be designed to account for severe weather events including the changing conditions predicted in worst-case climate change scenarios over the life span of the Project. In this regard, design considerations that include climate change-induced severe events are typically applied to new industrial developments. Given these factors, the effects of the environment on the Project are considered to be insignificant.

It is understood that special consideration must be made to consider the effects of even minor environmental impacts on the rights of Canada's aboriginal peoples. Furthermore, every effort will be made to advance positive project impacts of the human environmental condition of First Nations communities. To this end, the Project will conduct ongoing, formal and routine meetings with representatives from the Mi'kmaq First Nations to identify any such impacts and to determine appropriate mitigations measures. These discussions will be conducted in accordance with the terms established under the Collaborative Benefits Agreements undertaken for this Project.

12.3 Cumulative Effects

This assessment inherently includes an evaluation of the cumulative effects of existing and past projects since these effects are already present in the description of the existing environment. In addition, this assessment considers the cumulative effects from other potential projects that are likely to occur in the foreseeable future. These projects include:

1. Chedabucto Aggregates Quarry Expansion (Halfway Cove, MODG)
2. Goldboro Liquefied Natural Gas Project (Goldboro, MODG)
3. Maher Melford Container Terminal (Melford, MODG)
4. Bear Head Liquefied Natural Gas Project (Port Hawkesbury, Cape Breton)

As described in Section 9.3, Shipping and Navigation and Local Economy, Land and Resource Use aspects of the Melford Container Terminal and the Bear Head Natural LNG Projects are expected to overlap with the residual effects of the Black Point Quarry Project. Taking into account the basic mitigation measures described in Section 9.3, the residual adverse cumulative effects expected with respect to Shipping and Navigation are predicted to be insignificant. Cumulative effects to the Local Economy, Land and Resource Use are expected to be positive and potentially significant over the medium to long term.

Cumulative effects on First Nations are a special consideration. Some cumulative impacts may result in small changes in abundance or distribution of food resources. This can result in changes in areas of primary hunting activity. While it is expected that there will be no significant impact from the Black Point Quarry, cumulative effects on wildlife and fish in the area will be a matter of routine discussion with Mi'kmaq First Nations as part of the formal and routine

meetings undertaken during the course of negotiations regarding the Collaborative Benefits Agreements. In other instances the cumulative effects of multiple developments in the region can have a positive impact on the social and economic environment for the Mi'kmaw. It is possible that there could be a positive cumulative impact on the social condition of Mi'kmaq harvesters as multiple projects are undertaken that could provide useful and necessary employment employing Mi'kmaq marine and environmental skills for the mutual benefit of several projects. Every effort will be made to advance these effects through discussion with the Mi'kmaq.

12.4 Conclusions of the Proponent

As progressively described within this EIS, a series of Project-environment interactions can be expected during the construction, operation and decommissioning of the Black Point Quarry Project. These interactions and their resulting effects on the environment are entirely consistent with and typical of environmental impacts of natural resource development projects in Nova Scotia and elsewhere in Canada. For many reasons the Project site is well suited for a quarry operation. The large, chemically stable granite resource is not used as a potable water supply, the nearest residential properties are not situated at the property boundary but rather hundreds or thousands of meters away, the quarry face is directed across open water rather than toward residential development, the resource is located near a deep water, ice free shipping route to a major commercial market, prime fishing areas can be avoided or in the case of lobster habitat occupied by the marine terminal, can be recreated through offset compensation measures in the immediate vicinity, etc.

Given these considerations and a number of others, the Proponent concludes that the Project is not likely to result in any significant adverse environmental effects. In contrast, the Black Point Quarry Project is expected to result in long term direct and indirect employment opportunities, in addition to other positive economic benefits for the local, regional and provincial economies.

Table 12-1: Summary of Residual Adverse Effects, Significance Thresholds, Significance of Residual Effects

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
Air Quality and Climate Change		
Fugitive dust emissions from site preparation, quarrying, crushing, stockpiling, vehicle traffic and off loading	An exceedance of the Nova Scotia or CCME ambient air quality standards at a residential or commercial location outside the property boundary, where the exceedance is due to emissions from the operation and the event occurs more than twice in the period of time that the standard is based	Not Significant
Emissions of fuel combustion products from site vehicles and generators	As above	Not Significant
Noise (Terrestrial)		
Ambient noise perceived by residents living around the site during construction (road building, vehicle traffic, blasting, crushing, marine terminal construction)	An exceedance of the maximum noise or vibration limits listed in the <i>Pit and Quarry Guidelines</i> at or beyond the property boundary, where the exceedance is due to noise from the operation and the event occurs more than twice in the period of time that the standard is based.	Not Significant
Ambient noise perceived by residents living around the site during operation (blasting, loading, crushing, screening, offloading)	As above	Not Significant
Ambient Light		
Increased ambient light from the Project construction and operation, including operation of the marine terminal	Direct light trespass that according to the affected resident regularly interferes with the use and enjoyment of nearby residential properties on a permanent basis.	Not Significant
Attraction or disturbance of nocturnal wildlife and/or migrating birds	Evidence of unacceptable levels of bird mortality associated with Project lighting (mortality or injury of ten or more migratory birds in a single event, or of any number of species at risk birds).	Not Significant
Geology, Soil and Sediment Quality		
Surface water discharge to the marine environment	An accidental release of low pH, acid rock drainage to the marine environment.	Not Significant
As above	An accidental release of total suspended solids in	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
	excess of the maximum values listed in the CCME (1999) Water Quality Guidelines for the Protection of Aquatic Life (Marine) and/or the Nova Scotia Pit and Quarry Guidelines (NSEL 1999).	
Groundwater Resources		
Reduction in groundwater recharge to offsite surface water features; changes to groundwater quality	A decrease in groundwater supply to Adjacent Areas by 20% and/or an impairment in water quality such that groundwater discharge to surface waterbodies no longer meets Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 1999 as updated).	Not Significant
Marine and Surface Water Resources		
Changes to surface water quality	Discharge from the site exceeds the liquid effluent discharge standards in the <i>Pit and Quarry Guidelines</i> (NSEL 1999) or criteria listed in the CCME <i>Canadian Water Quality Guidelines for the Protection of Aquatic Life</i> , both freshwater and marine (CCME 1999).	Not Significant
Effects on Reynolds Brook and Murphys Lake from diversion of surface and groundwater into the pit over time	<p>A predicted change in the mean annual runoff within any off-site watercourse, or flow into any water body which changes by 20%.</p> <p>A predicted change in peak flow of water discharged from the site which will measurably increase the risk of flooding to downstream watercourses</p>	Not Significant
Terrestrial Ecosystems		
Habitat loss / plant mortality	A decline in abundance and/or a change in distribution beyond which natural recruitment would not return the population to its pre-project level within several (3-5) generations.	Not Significant
Wetlands		
Progressive habitat loss due to Project construction and operation over 50 years	An effect that is likely to cause a permanent net loss of wetland function as established during the wetland evaluation.	Not Significant following compensation
Changes to wetland hydrology and water quality resulting in habitat loss	As above.	Not Significant
Terrestrial Wildlife		
Habitat loss / fragmentation	An effect that causes a decline in abundance and/ or	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
	a change in distribution beyond which natural recruitment would not return the population to its pre-project level within several (three to five) generations	
Wildlife disturbance	As above	Not Significant
Disturbance of seabirds and waterfowl	As above	Not Significant
Freshwater Species and Habitat		
Effects on Reynolds Brook from diversion of surface and groundwater into the pit over time	A permanent, irreplaceable loss of Freshwater Species and Habitat that are part of or support a commercial, recreational or Aboriginal fishery.	Not Significant
Marine Species and Habitat		
Temporary noise and vibration effects to marine biota	<ol style="list-style-type: none"> 1. Adverse and irreversible changes to critical habitats; 2. Serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or to fish species that support such a fishery; 3. Permanent impairment of the ecological functioning of the biotic community; and/or 4. Increased ecological risk to a level that long term effects to the health of aquatic biota is predicted. 	Not Significant
Permanent loss of habitat resulting from the construction and operation of the marine terminal	As above	Not Significant following Offset
Species at Risk (SAR)		
Terrestrial Flora and Fauna SAR/SOCC - Clearing and site preparation will result in habitat loss and fragmentation and SOCC plant mortality	An effect that causes a decline in abundance and/ or a change in distribution beyond which natural recruitment would not return the population to its pre-project level within several generations and/or an adverse effect that causes a net loss of habitat function	Not Significant
Terrestrial Fauna SAR/SOCC - Change in behavior as a result of noise and light (including blasting).	As above	Not Significant
Marine SAR/SOCC - Loss of fish habitat due to construction of	As above	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
marine terminal		
Marine SAR/SOCC - Disturbance and potential change in behavior due to noise from ship traffic, pile driving and blasting	As above	Not Significant
Economy, Land and Resource Use		
Change in land use from occasional recreational/trapping to quarry, with resulting limitations on these activities	Pervasive change in land use patterns within the Study Area that adversely affects a community's use of that land and/or is inconsistent with a designated land use established through a municipal planning process.	Not Significant
Tourism and Recreation		
A decrease in wilderness/nature oriented recreation and tourism within the Project Area and vicinity due to vessel traffic and actual or perceived noise, dust and light	A permanent and widespread change in tourism or recreational activities such that people are no longer able to undertake these activities within the municipality and/or that result in a significant loss of tourism related revenue to local businesses.	Not Significant
Commercial Fisheries		
Temporary loss of lobster fishing grounds due to the marine terminal construction and operation and, as a result, displacement of fishermen into other areas	<ol style="list-style-type: none"> 1. An uncompensated loss of habitat of those fish species that are used for, or support commercial, recreational and/or Aboriginal fisheries; or 2. A sustained decrease in earnings from a fishery due to lower catch quantity and/or quality, or increased fishing costs (i.e., due to longer travel times, loss of gear, additional license fees, etc). 	Not Significant following Offset
Archaeological and Heritage Resources		
None anticipated	An uncontrolled disturbance to, or destruction of, any historical resource considered by the First Nations, provincial regulators or local residents to be of major importance.	Not Significant
Aboriginal Land and Resource Use		
Loss of future opportunities to harvest traditional terrestrial resources on portions of the property (there is currently no harvesting on the site)	Loss of fishing employment/income that could not be replaced within a reasonable time, loss of food resources not present in reasonable proximity to communities, or permanent loss of cultural relationship with the lands, flora and fauna.	Not Significant

VC and Residual Adverse Effects	Threshold for Determination of Significance	Significance of Residual Adverse Effect
Harm to or dispersion of local wildlife; Potential depreciation of the quality of local food and medicinal plants; Potential degradation of the local marine and shoreline habitats	As above	Not Significant

13.0 ACRONYM LIST

AAROM - Aboriginal Aquatic Resource and Oceans Management

ACCDC – Atlantic Canada Conservation Data Centre

AICFI - Atlantic Integrated Commercial Fisheries Initiative

APA - Atlantic Pilotage Authority

AQI – Air Quality Index

Amsl - above mean sea level

ARIA – Archaeological Resource Impact Assessment

ARTM – Atlantic Road and Traffic Management

asl – above sea level

bgs – below ground surface

BMP – Best Management Practice

BP – (Years) Before Present

CAC – Criteria Air Contaminants

CBA – Collaborative Benefits Agreement

CCG – Canadian Coast Guard

CCME – Canadian Council of Ministers of the Environment

CD – Chart Datum

CEAA – Canadian Environmental Assessment Act

CEAA 2012 – Canadian Environmental Assessment Act, 2012

CEA Agency – Canadian Environmental Assessment Agency

CEAR – Canadian Environmental Assessment Registry

CEPA – Canadian Environmental Protection Act

CHS – Canadian Hydrographic Services

CIS – Canadian Ice Service

CLC – Community Liaison Committee

CO – carbon monoxide

CO₂ – carbon dioxide

CO₂e – carbon dioxide equivalent

COSEWIC – Committee on the Status of Endangered Wildlife in Canada

CRA – commercial, recreational, or Aboriginal

CSA – Canadian Standards Association

CSAS - Canadian Science Advisory Secretariat

CWS – Canadian Wildlife Service

DFO – Fisheries and Oceans Canada

DHV – Design Hourly Volume

DWA – Deer Wintering Areas

EA – Environmental Assessment

EC – Environnement Canada

ECAREG - Eastern Canada Vessel Traffic Services Zone

ECM – Environmental Compliance Monitoring

EEM – Environmental Effects Monitoring

EHS – Emergency Health Services

EIS – Environmental Impact Statement

ELC – Ecological Land Classification

EMP – Environmental Management Plan

EPP – Environmental Protection Plan

FN – First Nation

FWAL – Freshwater Aquatic Life

MOU – Memorandum of Understanding

MPA – Marine Protected Area

MRI - Marshall Response Initiative

MSDS – Materials Safety Data Sheets

MWL – Mean Low Water

NAFO – Northwest Atlantic Fisheries Organization

NB – New Brunswick

NBCC – National Building Code of Canada

NFPA – National Fire Protection Association

NH₃ – ammonia

NO₂ – nitrogen dioxide

NO_x – nitrogen oxides

NPA – *Navigation Protection Act*

NPRI – National Pollutant Release Inventory

NRCAN – Natural Resources Canada

NS – Nova Scotia

NSDA – Nova Scotia Department of Agriculture

NSDAF – Nova Scotia Department of Aquaculture and Fisheries

NSDE – Nova Scotia Department of Energy

NSDNR – Nova Scotia Department of Natural Resources

NSDTCH – Nova Scotia Department of Tourism, Culture and Heritage

NSE – Nova Scotia Environment

NSEA – Nova Scotia *Environment Act*

NSEL – Nova Scotia Department of Environment and Labour

NSESA – Nova Scotia Endangered Species Act

NSF – Nova Scotia Department of Finance

NSFA – Nova Scotia Federation of Agriculture

NSGSAR - Nova Scotia's Ground Search and Rescue

NSMNH – Nova Scotia Museum of Natural History

NSPI – Nova Scotia Power Incorporated

NSTIR – Nova Scotia Department of Transportation and Infrastructure Renewal

NSUARB – Nova Scotia Utilities and Review Board

NSWA – Nova Scotia Wildlife Act

NWPA – Navigable Waters Protection Act

PAIR - Pre-Arrival Information Report

PID – Property Identification Number

PEI – Prince Edward Island

PEL – Probable Effects Level

PET - Potential Evapotranspiration

PIRI – Partners in RBCA (Risk-Based Corrective Action) Implementation (various countries; environmental program)

PM - Particulate Matter

PM₁₀ – PM with aerodynamic diameter less than a nominal 10 micrometers

PM_{2.5} - PM with aerodynamic diameter less than a nominal 2.5 micrometers

POL – petroleum-oil-lubricant

RBCA – Atlantic Risk-Based Corrective Action

RMP – Risk Management Plan

ROW – Right-of-Way

SAR – Species at Risk

SARA – Species at Risk Act

SO₂ – sulphur dioxide

SO_x – sulphur oxides

SOCC – Species of Conservation Concern

SPA – Scallop Production Area

SQG – Sediment Quality Guidelines

TAC – Total Allowable Catch

TC – Transport Canada

TERMPOL – Technical Review Process of Marine Terminal Systems in Transshipment Sites

the Agency – Canadian Environmental Assessment Agency

the Project – Black Point Quarry Project

the Proponent – Vulcan Materials Company

TOR – Terms of Reference

TRS – Total Reduced Sulphur

TSP – total suspended particulates

TSS – total suspended sediments

UNESCO – United Nations Educational, Scientific and Cultural Organization

US – United States

USACE – United States Army Corps of Engineers

USEPA – United States Environmental Protection Agency

UTM – Universal Transverse Mercator

VC – Valued Component

VOC - Volatile Organic Compound

VTSS Vessel Traffic Services

WHMIS – Workplace Hazardous Materials Information System

WHO – World Health Organization

WMP – Waste Management Plan

WNS – White-Nose Syndrome

14.0 LIST OF UNITS

% - percent

µg/kg – micrograms per kilogram

µg/L – micrograms per litre

µg/m³ – micrograms per cubic metre

µS/cm – microseimens per centimetre

µS/m – microseimens per metre

cm – centimetre

dB – decibels

dB (LA_{max}) – decibels (Maximum Sound Level)

dB (L_{eq}) – decibels (Equivalent Sound Levels)

dB re 1 µPa – decibel micropascals

dB (A) – decibels (A-Weighted)

dB (Lin) – decibels (Unweighted)

dbh – diameter breast height

g/s – grams per second

ha – hectare

kg – kilogram

km – kilometre

km/h – kilometres per hour

km² – square kilometre

kVA – kiloVolts-amps

kW – kilowatt

kW/m² – kilowatt per square metre

L – litre

L/d – litres per day

Ldn – Day-night level

LMP – litres per minute

m – metre

m/s – metres per second

m² – square metres

m³ – cubic metres

m³/d – cubic metres per day

m³/h – cubic metres per hour

mbar (g) – millibars (gauge)

mg/kg – milligrams per kilogram

mg/L – milligrams per litre

mg/m³ – milligrams per cubic metre

mm – millimetre

Mt – million tonnes

Mtpa – million tonnes per annum

MW – megawatt

NTU – Nephelometric Turbidity Units

ng/L – nanograms per litre

°C – degrees Celsius

ppb – parts per billion

ppm – parts per million

ppmv – parts per million (volumetric)

ppt – parts per thousand

t – tonne (metric tonne)

t/d – tonnes per day

t/y – tonnes per year

V – volt

1.0 INTRODUCTION

SLR Consulting was retained by Vulcan Materials Group and Morien Resources Corporation to conduct a hydrogeological assessment of a proposed aggregate quarry in Guysborough County, Nova Scotia. The assessment and description of hydrogeological conditions within the vicinity of the site was conducted in accordance with and is a requirement outlined in the “Guide to Preparing an EA Registration Document for Pit and Quarry Developments in Nova Scotia” (Nova Scotia Environment [NSE], 2009) and the guidelines provided for the site by the Canadian Environmental Assessment Agency (CEA Agency 2014).

1.1 Site Description

The proposed Black Point Quarry Project is located on a 354.5 ha property along the south shore of Chedabucto Bay, approximately 4.0 km west of the village of Fox Island in Guysborough County, Nova Scotia. The Project site location and study area is presented on Drawing 1.

The proposed quarry land is currently zoned by the Municipality of the District of Guysborough (MODG) as Heavy Industry (M-2).

The site is greenfield (undeveloped) and covered by thin soils, which sustain tall shrub and some coniferous forest. The site features numerous wetlands and a lake (Fogherty Lake). Topography on the site slopes in all directions away from a granite hill, located within the southern central part of the site. This granite is the target resource for the proposed quarry.

1.2 Proposed Development

The proposed quarry will extract the granite beneath the hill which has minimal overburden covering it. The quarry at full build out will be approximately 130 m deep and will occupy a footprint of 180 ha. Processing including secondary crushing, screening, washing will be undertaken on a 28 ha platform situated on lower land between the quarry and the coastline. The aggregate will be exported by ship via a marine terminal and load-out facility, to be constructed north of the processing platform.

1.3 Objectives

The objectives of this hydrogeological assessment are based on Section 6.1.1 and 6.1.3 of NSE (2009) and section 9.1.2 of CEA Agency (2014). These objectives include:

- Provide a general description of the geological features of the proposed pit or quarry site including the surficial geology and bedrock geology;
- If acid slates are present, provide additional information to determine if the material is net acid producing / consuming. Use acid rock drainage (ARD) / metals leaching (ML) prediction information to predict water quality for effects assessment and to determine mitigation requirements for the project;
- Discuss the predicted effects on the identified geological formations and how the effects will be avoided or minimized;
- Provide a description of the hydrogeology at the site and the local and regional study areas, which will include;

- A review of the physical geography and the geology of the area as it relates to local and regional groundwater flow and aquifer / aquitards;
- A conceptual hydrogeologic model in plan and cross-section;
- An inventory and analysis of existing information on the hydrogeological conditions / groundwater resources in the project area, including published reports, geological maps, well record data;
- A pre-development water well survey to establish baseline well water quality and quantity;
- Measurements of hydraulic conductivity for all hydrogeological units in the project area; and
- Baseline analysis of groundwater quality at the site and within the local and regional study area.

In order to achieve these objectives, this report is divided into two main sections, the first of which relates to the host geophysical environment and the second of which relates to the groundwater resources contained therein.

2.0 GEOPHYSICAL ENVIRONMENT

2.1 Physiography, Topography and Geomorphology

The Project site falls within the Atlantic Coast Ecoregion which is located along the southeastern coast of Nova Scotia (Drawing 2). Ecoregions are characterized by distinctive, large-order landforms or assemblages of regional landforms, small order climates, water, soils, vegetation, and regional human activity uses and patterns, and are usually influenced by groundwater conditions.

The coastline south of Canso is highly embayed, and fault lines have had a strong influence on shaping deep inlets along the eastern shore of Nova Scotia. West of Canso, along the south shore of Chedabucto Bay where the project is situated, the coastline is generally straight with few embayments (Drawing 2).

The surface is composed predominantly of Paleozoic metamorphic and granite bedrock, mantled by a discontinuous veneer of stony glacial till. The presence of a high water table, caused by abundant rainfall and underlying low permeability bedrock support numerous wetlands throughout the region. Common wetlands in this Ecoregion include fens, salt marshes, and raised and flat bogs (Webb and Marshall 1999). These may or may not be groundwater fed.

The Project site is located in the Eastern Shore Ecodistrict, a subdivision of the Atlantic Coast Ecoregion. The influence of the Atlantic Ocean provides a consistent coastal climate which is reflected in the forests of the Ecodistrict.

The Project site is located on a granite hill with a maximum elevation of approximately 97 metres (m) above sea level (asl). This is one of the highest elevations in the region and places the Project site at the top of the local watershed. Topography slopes gently in all directions from the peak of the granite hill; to the north an abrupt change in elevation is observed at 60 m asl. The northwest edge of the property (north of Fogherty Lake) forms a granitic cliff, which descends from 60 m asl to the sea over a distance of about 150 m. This cliff is lower in the north-central and northeast portions of the property between Fogherty Head and Black Point,

where the topography levels off at approximately 20-30 m asl and gradually grades to the rocky coast (Drawing 3).

2.2 Soils and Sediment

Approximately 94% of the soils in Guysborough County have developed from glacial till, with the remainder being developed on alluvial or glaciofluvial deposits. Textures in the till soils range from sandy loam to loam in the upper layer, and in the parent material the soils range from gravelly sandy loam to clay loam. Textures in the alluvial and glaciofluvial soils range from gravelly sandy loam to silt loam in the surface layer and in the subsoil, the soils range from gravel to silt loam in the subsoil (Hilchey 1964).

Soils are thin to non-existent on the top of the granite hill that dominates the property. Soils thicken to the east and west at lower elevations where wetlands have developed. The soil map (Drawing 4) labels the Project site as “rockland”, defined as soil areas with 50% or more of rock outcrops or boulders. Isolated pockets of peat, defined as brown, poorly decomposed organic material 12 in. or more in depth, are shown adjacent to Fogherty Lake. A single occurrence of Wolfville Series soil is shown in the extreme southeast corner of the property. This soil consists of “moderately stony, dark brown friable loam over dark grayish brown sandy clay loam”. As noted above, this soil is developed from a parent material made of glacial till, in this case “firm dark reddish brown sandy clay loam glacial till” (SRI 1963).

2.3 Surficial Geology

Surficial geology in the vicinity of the Project site is described by the published geology maps (Stea *et al.* 1992; Stea and Fowler 1979). It is predominantly comprised of Pleistocene-age stony till up to 20 m thick which consists of a sandy matrix and material derived from local bedrock sources (Drawing 5). Three types of glacial till are found on the site. The granite till shown within the property boundary is yellow-brown in colour, loose and sandy. It averages 2 m thick but is up to 5 m thick in some areas. The quartzite till is bluish-greenish-grey in color, loose and coarser grained than the granite till; it averages 3 m thick but may be up to 20 m thick in some places. A thin band of red till developed on Halifax Formation bedrock is present along the coastal portion of the property.

Observations made on site indicate these tills are essentially absent on the top of the granite hill, but thicken on the slopes of the hill at lower elevations. The tills are well exposed along the coastline at Half Island Cove (Figure 1) and Fox Island Main. Dug wells, which are used more often than drilled wells in this area to provide potable water, are installed in these tills. Well records obtained from NSE indicate that surficial deposits are generally comprised of various mixtures of clay, sand, gravel and boulders and vary in thickness between approximately 1 m and 19 m, which is consistent with the geologic mapping.

Figure 1
Photo - View from the east side of Gaulman Point looking at glacial tills.

Glacial tills in the background of Figure 1 host dug wells along Half Island Cove Road. An outcrop of Halifax Formation bedrock and marine beach deposits are shown in the foreground.

Several drumlin¹ features are indicated along Highway 16 west of Hayden Lake; deposits in these areas are thought to be up to 30 m thick (Stea and Fowler 1979). Drumlin deposits are generally siltier than the rest of the stony till, as they incorporate material formed from the erosion and incorporation of older till units. An esker² feature comprising sand and gravel deposits is indicated north of Highway 16 in the vicinity of Hayden and Cavanaugh Lakes.

Core logs from on-site drilling of the granite aggregate resource indicate that surficial deposits over the majority of the Project site proposed for the quarry are thin (<2 m) or absent where granite outcrops at surface.

¹ Drumlin deposits are low, smoothly rounded, elongate mounds of glacial till, carved that way by the horizontal movement of glacial ice.

² Eskers are low, sinuous, elongate mounds of sand and gravel deposited in sub-glacial streams.

2.4 Bedrock Geology

2.4.1 Regional Geology Overview

Structurally, the Project site is located within the Meguma Terrane structural province, south of Chedabucto Bay. Chedabucto Bay lies on top of the Cobequid-Chedabucto Fault System, which separates the Meguma Terrane in the south from the Avalon Terrane in the north. The sedimentary rocks of the Meguma Terrane consist of primarily metamorphosed, fine-grained sandstones and shales, with minor amounts of volcanic and carbonate rocks in local areas. The Meguma Terrane was later intruded by younger granitic rocks (NSMNH 2014), including the granite that will be quarried as aggregate in the Black Point Quarry Project.

The regional geology at the Project site consists of Cambro-Ordovician age metamorphosed sedimentary rocks of the Goldenville and Halifax formations that were intruded by Devonian-age granite. Granite represents about 20-25 percent of the bedrock in Nova Scotia and is found throughout mainland Nova Scotia and Cape Breton. South of the Cobequid-Chedabucto Fault System, granite intrusions are found within sedimentary rocks of the Meguma Zone. The granite was generated during the Acadian Orogeny, when the Meguma sedimentary pile was squeezed against, and possibly over, the Avalon Zone (NSMNH 2014). The geology of the site and surrounding area is presented on Drawing 6.

2.4.2 Local Geology

The geology surrounding the Project site consists of Cambro-Ordovician age metamorphosed sedimentary rocks (metasediments) of the Goldenville and Halifax Formations. The Goldenville Formation is the oldest and is generally found to the south and west of the Project site, with some outcrop on the tip of the Fogherty Head / Black Point headland. The Goldenville Formation comprises a thickly bedded metawacke with minor metapelite (<5%). Photographs showing the Goldenville Formation in situ are presented in Figure 2.

Figure 2

Photo – Outcrop of Goldenville Formation showing vertical bedding and jointing.

Immediately to the south of the faulted boundary with the Goldenville Formation on the Fogherty Head / Black Point headland lies the Halifax formation, comprising a porphyroblastic, sulphide-bearing, graphite schist interbedded with thin layers of metawacke (Hill 1991). Figure 3 illustrates the highly deformed and sheared Halifax Formation in outcrop.

Figure 3
Photo - Outcrop of Halifax Formation (left) and shearing detail in closeup (right).

Based on provincial geologic mapping, the majority of the Project site, including the area to be quarried, is composed of a medium-grained, equigranular to slightly porphyritic granite with less than 4% biotite (Hill 1991). The granitic pluton has been intruded into the Goldenville Formation and the northern boundary with the Halifax Formation comprises a west-northwest to east-southeast trending, dextral strike-slip fault. This fault is consistent with the major structural fabric direction within the metamorphic rocks in the vicinity of the Cobequid-Chedabucto Fault System and is likely to be the dominant fracture orientation in the Halifax and Goldenville Formations. The boundary between the Halifax and Goldenville Formations between Fogherty Head and Black Point is also faulted.

Eleven core holes have been drilled in the Project site footprint in order to confirm the granite's suitability as a construction aggregate. Their drill logs are provided as Attachment A and locations shown on Drawing 7. The logs demonstrate a pinkish to greyish-white granite comprising 50% to 60% feldspar, 35% to 48% quartz and up to 10% biotite and muscovite mica.

The granite does not exhibit a structural fabric, i.e. it is massive as illustrated in the outcrop and core photographs in Figure 4, and is not sheared or deformed. The core logs indicate that the most frequent fracturing and jointing occurs in the upper 40 m as demonstrated by the fracture frequency plot in Attachment B. Two fault zones were noted in the core logs for BP-8 and BP-9 at 93 to 94 m bgs and 20 m to 25 m bgs respectively, and are shown on the fracture plots by fracture frequencies of >20 fractures per metre. Detailed topographic and LiDAR data of the site indicate a bifurcating lineament running from the northwest corner of Murphy's Lake to the minor watercourse to the northeast of Fogherty Lake. This northwest-southeast trend is consistent with known faulting in the area and may indicate the surface expression of a fault zone within the granite. Core holes BP-8 and BP-9 are located close to this lineament and intersect broken zones of rock which may be related to a fault or faults. This is of interest as these zones may provide preferential pathways for groundwater movement into the quarry in future.

2.4.3 Acid Rock Drainage Potential

The granite at the Project site will be quarried to produce crushed-stone aggregate. Analytical testing was conducted in 2014 on the granite taken from three boreholes drilled in the granite resource (BP-7, BP-8 and BP-9) to confirm its suitability as construction aggregate. Testing included analysis of weight % sulphur and acid production potential as indicators of acid rock drainage (ARD) potential, since ARD has both structural and environmental implications. Testing indicated that the concentration of sulphur / sulphide in the granite is well below the threshold indicated in the Sulphide Bearing Material Disposal Regulations (N.S. Reg. 57/95) and is therefore considered non-acid producing (Attachment C). This is fully consistent with the chemical composition of aggregate quality granite: even limited ARD potential would render the rock un-useable as aggregate.

Halifax formation slates, which are often sulphide bearing, and Goldenville formation quartzite and greywacke, which is rarely sulphide bearing, are present within the proposed Project area at the northern end of the site. These rocks underlay the area proposed for the processing plant and aggregate stockpiles. Although they will not be quarried for aggregate, these formations may be disturbed for construction of the laydown area and excavated rock may be used to construct the marine terminal.

In October 2011, Black Point Quarry project geologists collected samples from these formations for ARD analysis. Five of the six surface samples collected have sulphide contents below the 0.4% threshold stipulated in the Regulations (Dalton 2011 in Attachment D). One sample had sulphide above the threshold (i.e., 0.935%); however, the material was found to contain some neutralizing capacity with a pH of 7.4. From all indications, the Goldenville Formation rock on site is sulphide free and is proposed to be used in construction of the rubble-fill for the wharf. The Halifax Formation, which likely contains sulphides appears to exist only in a small band across the site (Attachment D) and will be avoided to the extent possible. The Proponent will sample and test these rocks prior to any excavation in accordance with the guidance provided in

the provincial Sulphide Bearing Material Disposal Regulations. Should sulphide bearing materials be disturbed, the Proponent will work with NSE and NSDNR to confirm that all regulatory requirements are met before excavation begins.

3.0 GROUNDWATER RESOURCES

The hydrogeological regime at the application site and the surrounding area is described in the following sub sections:

- groundwater wells and use;
- aquifer characteristics;
- recharge mechanisms;
- groundwater levels and flow; and
- groundwater quality.

The hydrogeological data has been used to develop a conceptual site model that has in turn been used to assess potential impacts associated with the proposed development. The model has also been used to determine appropriate mitigation measures.

3.1 Groundwater Wells and Use

The objectives of the residential well assessment were to establish baseline water quality conditions and to provide an assessment of the hydraulic parameters within the aquifers utilised by local residences adjacent to the Project site. Initially, a water well records search was undertaken by obtaining records from NSE, followed by a door-to-door survey of all residences within a 2 km radius of the Project site. A number of properties outside the 2 km radius were surveyed and sampled and/or yield tested in order to further assess the relevant aquifer units. At each residential well, a questionnaire was completed to determine the type of well (drilled or dug), well completion details, water levels and whether the well user has any issues with water quality or quantity. Details of the work undertaken at the residential wells are provided in Attachments E and F (AECOM 2014a and 2014b).

The majority of local wells (for which there are records) are utilized for domestic or commercial purposes. The NSE records indicated a total of 16 wells within the main settlements adjacent to the Project site; however 31 wells were identified by the door to door survey. These wells are located in the vicinity of the settlements of Half Island Cove (five well records) and Fox Island Main / Indian Cove (six well records) with several spread along Highway 16 (five well records) to the south of the site. Drawing 7 presents the locations of the wells identified from the records search and the door-to-door survey for which Table 1 summarizes the information collected.

The majority of drilled wells are between 30 m and 105 m below ground surface (bgs) and are screened within either the Goldenville or Halifax formations. There are no residential or commercial water wells drilled in the granite. The closest drilled well (BPRWA007) to the Project site is approximately 1 km to the south along Highway 16, however all of the other drilled wells recorded are greater than 2 km from the site.

Dug wells are between 1.8 m and 7.0 m deep according to measurements taken in the field. No lithological logs are available for the dug wells, however, based on their measured depth it is inferred that they are completed in the surficial deposits. Dug wells are by far the most common residential well type in the area, of which there are two (BPRWA008 and BPRWA013) within 1 km and five between 1 km and 2 km from the Project site.

(1) NSE = wells recorded in the NSE Well Logs Database; BPR = wells sampled for this study. Well owner's names withheld to protect privacy.

3.2 Aquifer Characteristics

A number of different geological units with different hydraulic properties are present in the study area. The distinct units are discussed here in order of increasing geological age. The testing of several residential wells was undertaken and details of the work are provided in Attachments E and F (AECOM 2014a and 2014b). However, due to difficulty obtaining accurate discharge rates and interruptions in pumping and recovery tests due to household water system interference, any figures quoted for household wells BPWRA001 and BPRWA007 are approximations.

3.2.1 Surficial Deposits

Surficial deposits, where present, consist of stony till and related drumlin and esker deposits. Intergranular flow predominates in the sandy matrix and the hydraulic conductivity is locally highly variable, having low conductivity where clay rich material predominates and higher conductivity where interconnected sand is present. A number of dug wells, described in Section 3.1, are present in the area. These wells are installed into the surficial deposits for potable water supply domestic purposes, indicating that the surficial deposits are locally important aquifers. Such water supplies usually obtain their water from localized recharge of precipitation.

An in-situ variable head permeability test has been undertaken in residential well BPRWA001 by undertaking a short term pumping and recovery test. No other dug residential wells were available for yield testing. Test results were analysed using the Theis Recovery method as hosted by AquiferTest (v3.5) software to obtain hydraulic conductivity values. A copy of the analysis undertaken is presented in Attachment G. The test results show that the surficial deposits have an approximate hydraulic conductivity of 2×10^{-6} m/s with a transmissivity of 2×10^{-5} m²/s. The hydraulic conductivity value obtained at this residential well is at the upper end of the generally recognized spectrum for glacial tills (10^{-6} to 10^{-12} m/s Freeze and Cherry, 1979). Given the sandy nature of this glacial till, such a result is expected.

3.2.2 Granite

The granite bedrock is a crystalline igneous rock, and as such has negligible primary (intergranular) porosity, so all groundwater storage and flow occurs within the joints and fractures. The fracture frequency plot in Attachment B indicates that the highest frequency of fractures within the granite occurs in the upper 40 m. These fractures are likely to represent various types of joints and discontinuities caused by tectonic stresses, cooling of the granite, the release of pressure upon the rocks due to overburden removal and chemical or physical weathering. Two fracture zones were noted in the core logs for BP-8 and BP-9 that may be evidence of faulting, and depending on their nature may act as preferential pathways or boundaries to groundwater flow. It is considered likely that the majority of groundwater flow in the granite takes place in the upper 40 m based on the fracture frequency.

Given the remote nature of this site and low risk of effects on private wells, packer testing was not undertaken on the core holes.³ To provide initial hydraulic conductivity information, a number of slug, and pumping and recovery tests were undertaken on granite core holes BP-5, BP-7, BP-8 and BP-9 in 2014. Details of the work undertaken at the granite core holes are

³ It is anticipated that further hydraulic conductivity testing would be undertaken as the monitoring network is developed as per Section 3.7.4.

provided in Attachments E and F (AECOM 2014a and 2014b). The slug tests were conducted using a solid slug with instantaneous head changes in the wells and the pumping and recovery tests were undertaken by pumping for between 25 minutes and 140 minutes. To obtain hydraulic conductivity values, the slug tests were analysed using the Bouwer-Rice method and the recovery tests were done using the Theis recovery method, both hosted in the AquiferTest (v3.5) software. A copy of the analysis undertaken is presented in Attachment G. Initial slug tests indicated hydraulic conductivities of approximately 6×10^{-7} m/s to 7×10^{-7} m/s, however, later pumping and recovery tests indicated hydraulic conductivities of 2×10^{-7} m/s to 6×10^{-7} m/s. It is considered that the longer pumping and recovery tests give a better idea of the bulk granite properties due to their larger water level changes and radius of influence around the wells. These values are typical of low yield wells.

3.2.3 Cambro-Ordovician (Meguma) Metasediments

The Cambro-Ordovician metasediments of the Goldenville and Halifax Formations are primarily comprised of slate, shale and quartzite and demonstrate low intergranular porosity due to their relatively high degree of metamorphism. Secondary fracture porosity is likely to be responsible for the yields obtained from residential wells in the vicinity of the site. A number of residential wells in the area are drilled into the Goldenville and Halifax Formations indicating that the aquifers are at least locally important for groundwater supplies.

Nova Scotia Environment records indicate two yield tests in wells in the vicinity of the Project site, with one in the Halifax Formation with a calculated hydraulic conductivity of 1×10^{-6} m/s and the second in the Goldenville Formation with a calculated hydraulic conductivity of 7×10^{-7} m/s. A yield test was completed in the drilled well BPRWA007; however, the pumping rate during the test is not known and was not possible to estimate because of the configuration of the water supply system (AECOM 2014a). The most complete recovery test was therefore analysed as a slug test using the KGS method in Aqtesolv. The analysis gave an estimated hydraulic conductivity of 6×10^{-8} m/s. A copy of the analysis undertaken is presented in Attachment G.

3.2.4 Summary

In summary these hydraulic conductivity values are compared here:

- the **surficial till** deposits had an approximate hydraulic conductivity of 2×10^{-6} m/s;
- the fractured **granite** hydraulic conductivities were 2×10^{-7} m/s to 7×10^{-7} m/s;
- the **Halifax Formation** had a measured hydraulic conductivity of 1×10^{-6} m/s; and
- the **Goldenville Formation** had a measured hydraulic conductivity of 7×10^{-7} m/s

While it is recognized that these measurements do not establish the full range for each unit, they do provide insight into the aquifer characteristics. It is commonly held (Freeze and Cherry, 1979; Fetter 2001) that useable aquifers have a hydraulic conductivity of greater than 1×10^{-6} m/s. Only low yield wells are possible below that value. The surficial till has a value higher than this, but not by much, due primarily to the fine grained soils entrained in the glacial till. This is not a regionally connected surficial aquifer, but rather pockets of localized aquifer material, that derives its water from localized recharge on the scale of the host lot.

All three bedrock types have hydraulic conductivities less than 1×10^{-6} m/s. The granite appears to have the lowest range. It must be kept in mind that these test results are for wells and boreholes where only the most permeable horizons were screened and tested (the granite boreholes are not screened at all). The host rock in all three formations will have hydraulic

conductivities two or three orders of magnitude lower (10^{-9} to 10^{-8} m/s) than the calculated values. It is reasonable to conclude that there are no regional aquifers in these bedrock units, but rather fractured zones that locally provide water to isolated wells. Based on the fracture plots presented in Attachment B, the upper 40 m of the bedrock provides the best opportunity for such wells.

3.3 Aquifer Recharge

Precipitation falling onto a catchment either evaporates, is lost to plant transpiration, infiltrates to groundwater, or runs off as storm water to forests and wetlands. An estimate of the average recharge to groundwater in the area was calculated by applying infiltration factors based on topography, soils and vegetation (Main Report, Appendix C). Infiltrating water that is not taken up again by plants from the rooting zone migrates to the shallow water table, and at that point is considered to be aquifer recharge. An average annual infiltration of 351 mm was derived for the entire site. This varies from location to location on site, generally being more in the flatter areas with significant overburden, and less on the steeper rocky areas.

3.3.1 Definitions

There are a variety of terms used by the technical community when describing water balance mechanisms, depending upon the technical background of the user. For the reader's convenience the terms used in this report have been defined in the following manner:

Precipitation: Includes both rainfall and snowfall (as water).

Evapotranspiration: This is the water that is either evaporated from open surfaces, or is taken up by plant transpiration and returned to the atmosphere.

Potential Evapotranspiration: This is the amount of evapotranspiration that would occur if there was unlimited water available.

Actual Evapotranspiration: This is the amount of evapotranspiration that occurs based on the availability of water, and considers temporary storage in the soils above the water table.

Surplus: this is the difference between precipitation and the actual evapotranspiration. This water is available for run off or infiltration into the ground.

Infiltration: this is the water that soaks into the ground and does not runoff. It can be partly removed by plant uptake.

Recharge: This is the remaining infiltration that is not taken up by plants, and reaches the water table.

Surface Water Flow or Runoff: This is the portion of the water surplus that moves laterally on the ground surface and does not infiltrate.

Groundwater Flow: Once water has entered the subsurface it is deemed to be groundwater and moves under gravity and other natural groundwater pressures. It can subsequently re-emerge as groundwater discharge into surface water bodies. At this site groundwater flow occurs locally in the overburden and in the bedrock.

Subsurface Runoff: This term is not used in this report, but is occasionally used to describe the shallow movement of groundwater that rejoins the surface water system. Sometimes also called “interflow”, although that term is not used in this report.

3.3.2 Surficial Deposits

Where present, the glacial deposits influence recharge to the underlying bedrock aquifers. Recharge to groundwater relies on the retention time of surplus water (after evapotranspiration) on the landscape. The glacial deposits accept rainwater infiltration and act as a temporary storage reservoir (on a local scale) allowing it to recharge the less permeable bedrock below. Where the overburden is thin, infiltrating groundwater will deflect along the low permeability bedrock, and unless it intersects fractured rock, it will flow in the shallow groundwater ultimately discharging to the creeks or wetlands, or perhaps simply to thicker deposits of overburden further downhill.

3.3.3 Bedrock

Drawing 12 was prepared by partitioning the average annual water surplus based on soils/bedrock, topography and ground cover, in a GIS platform. It shows that recharge is typically less than 200 mm in the topographic high areas that exhibit exposed bedrock. Values of 200 to 300 mm are found in the areas of moderate overburden and less steep slopes. In the flatter areas, where the overburden is thickest, typically in the low lying areas, the recharge rates exceed 300 mm/yr and can locally approach 700 mm/yr. (The average annual surplus is 877 mm/yr, and this implies that only 177 mm will runoff in those areas.) Notwithstanding this wide variance across the site, the average annual recharge for the entire site is 351 mm/yr, as stated above.

3.4 Groundwater Levels and Flow

A total of eight granite core holes were installed at the Project site in late 2007 / early 2008, and three additional holes were drilled in early 2014. These core holes were left open with shallow surface casings and thus transect the whole quarry and provide a groundwater elevation representative of the most permeable horizon within the granite. The locations of these core holes are shown on Drawing 7.

The information from these wells has been supplemented with groundwater level information from the residential wells presented in Drawing 7 and a series of drive point piezometers installed within the wetland areas surrounding the site, the locations of which are presented on Drawing 8. Nine locations were instrumented with drive point piezometers which were installed in wetlands and streams to assess the vertical gradient of shallow groundwater. In the wetlands, the piezometers were installed as nested pairs with one deep and one shallow piezometer. The vertical gradient can be used to infer whether the wetlands are formed by groundwater discharge or whether they form an area of groundwater recharge. In the streams, a single piezometer was installed in the stream bed so a comparison between the groundwater level beneath and the surface water level can be made, and the stream defined as losing or gaining based on the direction of the vertical hydraulic gradient.

The groundwater monitoring points at the Project site have been subject to periodic groundwater elevation measurements between June and August 2014, with a previous round of water levels being collected in September 2011. Four of the granite core holes (BP-5, BP-7, BP-8 and BP-9) have been recording continuous groundwater levels using data loggers from 5 June

2014 to 28 August 2014 and two of the drive point piezometers (MP2 and MP6) have been monitoring groundwater and stream levels using data loggers since 24 July 2014. Groundwater hydrographs and summary tables of monitoring data to date are presented in Attachment H, a review of which shows:

- the highest groundwater elevations are recorded in on site borehole BP-4 (97.54 mASL) located at the high point of the Project site. This water level lies within the granite bedrock;
- the lowest groundwater elevations are recorded in residential well BPRWA012 (2.73 m asl) near the ocean in the settlement of Fox Island Main to the east of the Project site;
- groundwater elevations are all less than 6 m below ground surface in wells completed in granite, metasediments or surficial deposits and demonstrate that groundwater levels follow topography. This is probably due to the relatively lower hydraulic conductivity of the underlying bedrock, inhibiting drainage to depth;
- groundwater levels in those wells instrumented with data loggers have been declining since installation in June, which would fit with increasing evapotranspiration rates and lower infiltration during the summer months;
- all instrumented granite boreholes show a response to rainfall events to varying degrees, with groundwater levels in BP-8 and BP-9 increasing approximately 0.1 m during the most intense rainfall events whereas BP-5 and BP-7 increase by over 1 m during the same event. The upper part of the response curve in BP-5 is truncated at approximately ground level, which implies that this borehole is flooding from the surface during intense rainfall; and
- a small tidal influence in the order of 10 to 30 mm is seen in the granite boreholes as illustrated by the comparison of the daily high tide with the daily high groundwater level in Attachment H. The apparent lag between the daily high tide and the corresponding groundwater level high is approximately 8 hours. Given the wide topographical range found on site this small change over several hours on a measurement day does not affect the interpretation of the water table.

Using site groundwater observation data, Drawing 9 shows the regional potentiometric groundwater surface at site as recorded in July / August 2014. This interpretation incorporates site specific measurements in the bedrock boreholes, minipiezometer readings in the wetlands and creeks, and water levels estimated from the private water wells, as well as topographic lake levels and stream elevations. As such it is a general representation of the water table and is intended to give a sense of the horizontal direction of groundwater flow. Where no observation points exist, the level has been estimated from knowledge of the topography and the approximate depth to water table in similar settings across the site.

Drawing 9 demonstrates that the water table generally reflects the topographic pattern, as should be expected. Groundwater flows laterally from topographic highs towards the shallow lakes, creeks and valleys onsite. The dominant feature is the granitic pluton on site which drives lateral ground water flow either north or south. A groundwater divide is shown on Drawing 9. Groundwater in the ground to the north of this divide flows laterally towards Chedabucto Bay, and that south of the divide moves towards the creeks to the south. There are in addition local patterns created by local topographic highs and lows that cause easterly or westerly flow towards the local watercourses.

3.4.1 Groundwater / Surface Water Interactions and Wetland Function

As noted, drive point piezometers (sometimes called mini-piezometers because of their narrow diameter and shallow depth) were installed in selected creeks and wetlands to assess groundwater contributions to these features. Vertical hydraulic gradients within the drive point piezometer pairs can be used to indicate how the surface water bodies are gaining groundwater from or losing it to the ground.

The vertical gradients measured on 26 August 2014 indicate that five of the locations, including wetlands at MP1, MP2⁴ and MP5, along with streams at MP6 and MP8 indicate downward gradients which suggest aquifer recharge is occurring at these locations. Upward vertical gradients measured at wetland areas MP3, MP4 and MP7, along with the stream at MP9 indicate that discharge from the underlying soil is occurring at these locations. There is no pattern to the upward or downward hydraulic gradients with respect to locations in streams or wetlands. It is noted that the upward gradients are weak and likely localized, ranging from just 0.01 to 0.11 m/m (mean of 0.05 m/m upwards). On the other hand, the downward gradients are relatively stronger, ranging from 0.13 to 0.61 m/m, with a mean of 0.35 m/m downwards. A number of these early readings may also reflect un-equilibrated piezometers, similar to MP2. The summer season is generally a season of low water levels and gradients may only seasonally be downward. Therefore these conclusions should be considered preliminary only until further data are collected.

Diurnal fluctuations of the groundwater levels can be seen in the hydrograph data for both MP2 and MP6, in the order of 0.5 to 2 cm. The effect is more pronounced in the stream at MP6. These diurnal fluctuations are due to the increased evaporative and transpirative uptake of water during the day, with replenishment at night. It is expected this effect will decline in the off season and dominate during the spring to early autumn period.

3.5 Groundwater Quality

Groundwater samples have been collected from the majority of nearest residential wells, from both drilled wells in the metasedimentary rocks and dug wells in the surficial deposits. Since there are no private wells in the granite, groundwater samples were also collected from granite boreholes BP-5, BP-7, BP-8 and BP-9 on two occasions. On the first occasion, samples were collected using a bailer with a minimal purge of ten bailer volumes (~10 L) being removed from each borehole prior to sampling. On the second occasion, the wells were purged using a submersible pump until groundwater chemistry parameters including pH, electrical conductivity (EC), dissolved oxygen and temperature were considered to have stabilized. The water quality samples from both residential wells and granite boreholes were analysed for general chemistry and total metals for comparison purposes. Results of the water quality sampling are provided in Tables 2 to 4. A Piper plot and Box and Whisker Plots are presented Figures 5 to 7 in order to compare groundwater quality from various aquifer types at and around the site.

Figure 5 is a Piper plot showing the relationship between the relative abundance of the major cations and anions in the sampled water. These plots are helpful in understanding the differences between water types. The “field” that shows the water quality from granitic rock is

⁴ It is noted that the hydrograph for the deep piezometer at MP2 has been rising in a smooth curve. This indicates that the level in this piezometer has not yet reached a static equilibrium with the surrounding groundwater and therefore the apparent downward gradient may not be accurate.

shown in green on Figure 5. The field for the Meguma bedrock is shown in grey. These two fields overlap each other. This is because they are composed of similar mineralogies, even though their origin is different. The sandstone is composed of silicate minerals, as is the granite. The overburden water quality on the other hand overlaps in a small way, but lies on a mixing line that extends past the bedrock water fields. Since the local glacial till is composed of crushed local bedrock moved there by the glaciers, some similarity to the bedrock fields should be expected. The width of this field is probably due to mixing as discussed below.

On all three plots the stream water occupies a narrow field (shown in blue) exhibiting a sodium chloride rich water with little calcium or sulphate and with low alkalinity (expressed as $\text{HCO}_3 + \text{CO}_3$). The typical field for clean meteoric water is shown in light blue on this figure for ease of comparison. The salty signature of the stream water is inferred to be due to the prevalence of salt spray at surface which then gets washed into the streams. The fact that many of the shallow overburden wells, which obtain their recharge from local meteoric water, lie on a mixing line from the stream water to the bedrock water, shows a mix of surface water and water influenced by the soil materials⁵. The part of the overburden field that extends to the left on the diagrams may be more greatly influenced by clean meteoric water with no salt spray content. The five wells to the left in the overburden field are wells that are well inland from the shore. The wells that plot to the right in the overburden field are generally within 200 m of the shore.

⁵ There may be a contribution from road salt as wells often sit near the local road; however this has not been investigated as part of this assessment.

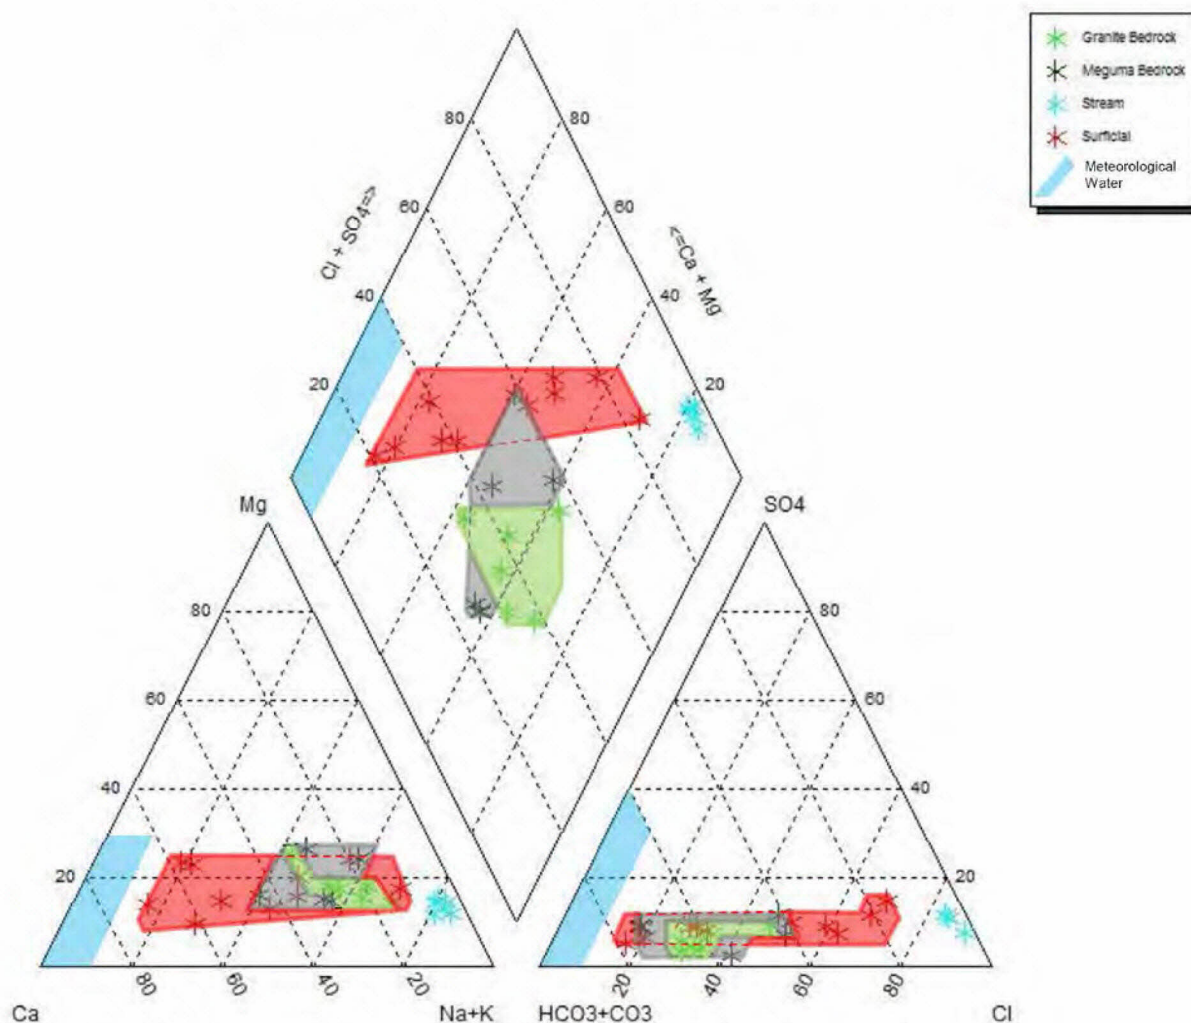

Figure 5
Piper Plot of Groundwater and Surface Water Quality Collected to Date

3.5.1 Surficial Deposits

Table 2 indicates that groundwater in the surficial deposits is of good quality for drinking, with the only exceedences of the Canadian Drinking Water Quality (CDWQ) guidelines occurring in the aesthetic objective parameters iron, manganese and pH, and a small number of exceedences of the turbidity CDWQ guideline. The groundwater quality in the surficial deposits is indicative of recharge from rainfall having a short residence time in the subsurface, where fewer parameters have time to dissolve in the groundwater. This is demonstrated on the Piper plot in Figure 5 which shows a distribution between Ca-HCO₃ waters typical of shallow, fresh groundwater and Na-Cl waters which are indicative of the influence of marine salinity provided in the recharge from precipitation (not saltwater intrusion). Concentrations of aluminium and iron as demonstrated in Figures 6 and 7 are low and consistent with the majority of recharge in the surficial deposits being provided by the infiltration of precipitation.

Table 2: Surficial (Dug) Residential Well Groundwater Quality Results

OG = Operational Guidance

AO = Aesthetic Objective

MAC = Maximum Allowable Concentration

Canadian Drinking Water Quality CDWQ Guidelines: Aug 2012

1. Duplicate Sample is BPRWA005

2. Aluminum Aesthetic Objective (CDWQ - AO): Conventional Treatment Plants = 0.1 mg/L (100 ug/L), Other Treatment Systems = 0.2 mg/L (200 ug/L)

3. pH Objective (CDWQ): 6.5 - 8.5

4. Calculated result only includes measured parameters. Actual TDS may be higher.

5. Sample results likely affected by water softner treatment system

BOLD RED Exceeds guideline

Figure 6
Box and Whisker Plot of Aluminium in Groundwater and Surface Water

3.5.2 Granite

Table 3 and Figures 6 and 7 indicate that groundwater in the granite has generally high concentrations of metals, with exceedences of aesthetic objectives for aluminium, colour, iron and manganese in the majority of samples, and exceedences of the maximum allowable concentrations within several samples for lead, arsenic and uranium. pH values were low in three of the eight samples, indicating slightly acidic conditions within the granite. We underline that the groundwater samples from within the granite have been assessed against the CDWQ

Guidelines for comparison purposes only: there are no residential or commercial wells in the granite bedrock and so, strictly speaking, these Guidelines do not apply. Regional maps indicate that concentrations of arsenic potentially exceeding national guidelines are considered very likely in the area (NSE 2005) and uranium is considered most likely to occur in areas containing granitic intrusions (NSE 2014).

The Piper plot in Figure 5 indicates that the majority of granite samples lie in a zone between Ca-HCO_3 , Na-Cl , and Na-HCO_3 waters, which indicates a mixture of influences from shallow fresh water, marine water and deeper waters influenced by ion exchange. This would be consistent with the mixture of fresher waters from the upper fractured zone within the granite and water from deeper within the granite core holes.

Figure 7
Box and Whisker Plot of Iron in Groundwater and Surface Water

3.5.3 Meguma Metasediments

Table 5 indicates that groundwater in the metasediments is generally of good quality with only one or two samples exceeding the aesthetic objectives for manganese and turbidity. However, two samples, plus a field duplicate, from residential well BPRWA007 demonstrated arsenic concentrations which exceed the CDWQ guideline. Generally, a higher probability of arsenic concentrations in water wells occurs in certain formations within the Meguma Terrane, including the Goldenville Formation which is associated with arsenopyrite, and a lower probability in others including the Halifax Group (Dummer et al. 2014). The Piper plot in Figure 5 indicates that the majority of metasediment samples lie in a zone between Ca-HCO₃, Na-Cl, and Na-HCO₃ waters which indicates a mixture of influences from shallow fresh water, marine water and deeper waters influenced by ion exchange. This would be consistent with the mixture of fresher waters from the upper metasediments and water from deeper within the bedrock residential wells. Although the influences on the general water chemistry are similar to those within the granite, it is comparison of the metal concentrations which demonstrates the true difference between the two distinct groundwaters. Metal concentrations, as illustrated by Figures 6 and 7 and Table 5, are relatively low within the metasediments and significantly higher within the granite.

3.6 Conceptual Model Discussion

The site is characterized by the topographic high created by an erosion resistant granitic pluton, some 95 m above sea level. This feature was intruded into metasediments of the Meguma Formation. These metasediments surround the site and host those few local residential wells that extend into the bedrock. (Most private wells are shallow and tap the more permeable glacial till overburden). Water quality in the two bedrock types (granite and metasediments) is similar with the exception of higher levels of dissolved metals (e.g., iron, aluminium and lead) in the granite. Uranium is also found in the granite but not in the other groundwater types. Arsenic is present in both the granite and the metasediments. This groundwater chemistry is entirely from natural mineral concentrations in the bedrock. The overburden groundwater is much more dilute, reflects local recharge of meteoric water, and exhibits a salt signature where close to the coast.

Drawings 10 and 11 are vertical cross-sections that run along the lines shown on Drawing 7. They have been prepared to illustrate the relationship between the various geological units, the site topography and the local wells. The likely groundwater flow paths shown on Drawing 10 demonstrate the relationship between recharge and discharge areas. The relative low permeability of the bedrock (even when fractured) is responsible for the high water table, which is generally never deeper than 6 m below ground surface. Groundwater recharge occurs in all the upland areas of the site, with lateral discharge occurring in localized low areas and in some creeks.

Drawing 9, discussed above, shows that horizontal groundwater flow under existing conditions is outward from the granite, primarily along the upper, more weathered bedrock. Fracture frequency analysis shows there is a stronger presence of fracturing in the upper bedrock, above the dashed line shown on Drawings 10 and 11, at a depth of about 40 m. This line is in fact

gradational as fracturing occurs throughout the geologic profile. Deeper water is more mineralized and shows the effects of a longer presence of water at depth. Stream water quality shows little influence of the bedrock; the relatively low pH is attributed to inflows from nearby wetlands. The distinct difference in the metals concentrations between the granite and the Meguma Formation indicates there is little mixing of groundwater between the two rock types. There will however be exchange of the shallow groundwater along the boundary between the two units, based on the higher degree of fracturing at the bedrock surface. All local water wells are very far away from this boundary and there are many intervening wetlands and creeks that act as discharge zones.

From a conceptual model point of view most recharge joins the shallow system and moves laterally to onsite low areas and ultimately offsite by the creek systems. To test this statement the quantity of water can be examined. Drawing 12 shows that the granitic pluton has about 200 mm/yr (0.2 m/yr) of recharge. A representative strip, one metre wide and 300 m long to the edge of the hill is examined. Multiplying the recharge by the area yields an annual average recharge volume of 60 m³. Using Darcy's principle the amount of water conveyed by a 40 m deep fractured bedrock pathway can be determined. The horizontal gradient (dh/dL), measured off the pluton on Drawing 9 is 0.065 m/m. Darcy states that the flow (Q) is equal to the hydraulic conductivity (K) multiplied by the hydraulic gradient and the cross-sectional area of flow (A = 40 m x 1 m = 40 m²).

This can be rearranged to express K as a function of these parameters:

$$\begin{aligned} K &= Q / (dh/dL \times A) \\ &= 60 \text{ m}^3/\text{yr} / (0.065 \times 40 \text{ m}^2) \\ &= 23.1 \text{ m/yr} \quad (= 7.3 \times 10^{-7} \text{ m/s}) \end{aligned}$$

This compares well to the upper end of the measured range of bedrock hydraulic conductivity (7 x 10⁻⁷ m/s). Based on this favourable comparison it may be reasonably concluded that the conceptual model for the granite works well. A similar calculation can be conducted on the more permeable (but thinner) overburden areas, which Drawing 12 shows has recharge rates typically around 400 mm/a. That calculation derives an overburden hydraulic conductivity of about 4 x 10⁻⁵ m/s which is about twice the top end of the measured range for the overburden. This of course will be lower because the greater depth of underlying bedrock will take some of this water. What is important is that these values fall within a reasonable measure of each other, providing further assurance that the conceptual model is apt.

It is helpful to understand the water balance for the site. The Surface Water Resources Technical Report (Main Report, Appendix C) provides the water budget and water balance for the existing condition. During operational conditions the precipitation that falls on the site will generate runoff, which will be collected and discharged to Chedabucto Bay. Section 3.7.2 below provides insight on groundwater inflow. Calculations indicate a likely maximum groundwater inflow of 66.2 m³/yr per lineal metre of the quarry face at full Project build out. Table 5 in that section shows that considering contributions from 4,040 m of lineal quarry face this represents 267,450 m³ of groundwater per year, or about 8.5 L/s. Design of the water handling facilities (i.e., pit sumps) will consider this amount, which will be lower at earlier stages

of the quarry⁶, as part of quarry discharge to Fox Bay. Once the quarry is closed, this amount (which comes from the surrounding rock) plus the direct precipitation on the quarry area will begin to fill the quarry, which will take in the order of a decade. At that point the surface water will decant to Fox Bay. Since the inflow is dependent on driving head, and the quarry water level will be 50 m higher than the quarry floor at that time, there will be a reduced rate of groundwater inflow at this new equilibrium. Section 3.7.2 estimates this to be at a rate of 6.2 L/s (Table 5). This is in addition to contributions from direct precipitation.

3.7 Anticipated Effects of Quarry Development on Water Supply

It is useful to understand what potential effects the proposed quarry may have on nearby bedrock groundwater uses. Removal of the rock will mean the creation of a “sink” in the groundwater system, up to 130 m deep in places at full Project build out. This will create an inward groundwater flow towards the quarry. Drawings 13 and 14 show the quarry at full build out, in 50 years. They also show the expected maximum drawdown to the water table, based on the following discussion.

3.7.1 Quarry Drawdown

It is prudent to examine the extent of drawdown back from the quarry to understand if there is potential for any impact to neighbouring potable water wells. Consideration was given to using a three dimensional groundwater flow model to achieve this, however given the size of the facility, insufficient groundwater monitors are present to properly calibrate such a model. However the size of the facility means that there are extensively long sidewalls, in the order of 500 to 1500 m long. Therefore a two dimensional vertical section along such a wall has been analysed by the method⁷ of Fetter, 2001 for a maximum quarry depth of 130 m. This method considers the hydraulic conductivity of the weathered and unweathered bedrock and of the overburden soils, and the amount of average annual recharge, and calculates the water table surface, assuming a 5 m seepage face at the quarry wall. It is calibrated by ensuring the water table lies below the ground surface and that the lateral groundwater flows (overburden, weathered rock and unweathered rock) sum to the amount of recharge entering the system. To help represent the variability of the system (fractured rock, variable recharge rates) a reasonable range in parameters is applied to help bracket the likely results.

Figure 8 presents the base case for this analysis taken at the average recharge rate of 351 mm/yr for the site. A range of hydraulic conductivity (K) for the bedrock has been used to show its effect on the extent of the drawdown cone. The maximum measured K was 7×10^{-7} m/s in the open boreholes. As this is believed to be contributed by the more weathered rock at the top of the boreholes, it is very likely that the deeper rock is less permeable. For this reason two other cases of $K = 7 \times 10^{-8}$ m/s and $K = 7 \times 10^{-9}$ have been calculated to determine a conservative estimate for drawdown. These two values represent unweathered bedrock that is 10 to 100 times less permeable than the weathered bedrock assessed by the testing. Inherent in the calculation is a 5 m thick layer of overburden at $K_{\text{overburden}} = 2 \times 10^{-6}$ m/s, which conveys part of the recharge laterally away⁸ from the quarry

⁶ It will be lower because of a smaller area of the quarry, meaning less contributing quarry face and lower driving heads until the quarry floor reaches its final depth.

⁷ Fetter details this methodology in Chapter 4.14 for Steady Flow in an unconfined aquifer, as adapted from other authors. This technique is widely used and often un-cited.

⁸ This is because the ground slopes away from the quarry at almost every point around its circumference.

Figure 8 shows that the radius of drawdown reaches a distance from the quarry face of 300 m for the most permeable case of $K = 7 \times 10^{-7}$ m/s. Where the rock is less permeable this reduces to 115 m and then to 60 m where $K = 7 \times 10^{-9}$ m/s. This is intuitively correct as the rock is less capable of drainage at these lower values and thus affects less of an area of recharge.

The system is also sensitive to the amount of recharge. In the above example, a recharge rate of 351 mm/yr was selected as that is the average for the site. However, examination of Drawing 12 shows that around the edges of the quarry the recharge rate is locally around 200 mm/yr. Figure 9 has been prepared to show the effect of this lower recharge rate on the drawdown for the range of hydraulic conductivities considered. Since the bedrock can convey a certain amount of water, the extent of the area of drawdown can be greater if there is less recharge to convey. That is, the drawdown of the water table extends further from the quarry in the lower recharge scenario. The radius of drawdown reaches a distance from the quarry face of just about 400 m for the permeable case of $K = 7 \times 10^{-7}$ m/s. Where the rock is less permeable this reduces to 160 m and then to 90 m where $K = 7 \times 10^{-9}$ m/s. This recharge rate is adopted as the most conservative “base case”, as it reflects the lower recharge amounts at the top of the quarry walls.

Consideration must now be given to the horizon that appears to me more fractured generally above 40 m depth. Section 3.2.2 identified that the transition is gradational, but for the sake of computation a discrete boundary has been used in Figure 10 on the base case. Figure 10 shows that the drawdown will extend further back from the face in a weathered zone of $K = 7 \times 10^{-7}$ m/s (the upper end of the measured range on site). The most conservative case for impact assessment would therefore be to assume the bedrock is at the high end of the hydraulic conductivity range, and that this extends to depth. This is because the extent of the drawdown cone is reduced when the lower unweathered zone is of lower hydraulic conductivity.

Figure 10: Predicted Drawdown with Weathered bedrock,
 $K_{\text{weath}} = 7\text{E-}7 \text{ m/s}$, Recharge = 200 mm/yr

It is important to understand the amount of water that would enter the quarry through the bedrock for this critical case. Considering a 1 m wide slice the amount of recharge is $0.200 \text{ m/yr} \times 1 \text{ m} \times 410 \text{ m} = 82 \text{ m}^3/\text{year}$. For the water table position derived by the calculation, $15.8 \text{ m}^3/\text{year}$ flows laterally in the overburden⁹ (and away from the quarry since it is constructed at the height of land). The remainder, $66.2 \text{ m}^3/\text{year}$, flows laterally in the bedrock into the quarry.

It is often prudent to cross-check theoretical calculations against field observations to understand if the calculated results are reasonable. In this case a similar condition is observed in nature. The groundwater under the 80 m scarp above the shore drains naturally to the north and is about 60% of the size that may be created inside the quarry. The water table follows this scarp quite closely as seen on Drawing 9, with a horizontal gradient of about 0.25. That is, for the 70 m or so drop in the water table on Drawing 9, there is a lateral distance of about 280 m back from the toe of the slope. The analytical model predicts up to a 400 m extent of lateral quarry drawdown, that is a horizontal gradient of $400/130 = 0.33$. This is considered in very close agreement to the naturally observed condition. (For example, to achieve the same extent as observed in nature would require a hydraulic conductivity of about $1.2 \times 10^{-7} \text{ m/s}$, that is only 70% greater than what was found in the core holes. This is reasonable since a naturally weathered surface is more permeable than the quarry face will be.) It is concluded that the drawdown from the completed quarry will be felt at a drawdown distance of 400 m or less. The nearest wells are many times that distance away and the presence of intervening watercourses (which act as hydraulic boundaries) dictates that these wells cannot be affected by the quarry.

⁹ This is based on a water table slope of 0.05 m/m, a saturated thickness of 5 m and a hydraulic conductivity of $2 \times 10^{-6} \text{ m/s}$, and was calculated by the method of Darcy.

3.7.2 Quarry Inflow of Groundwater

The above section described the anticipated drawdown of the water table from the excavation of the quarry. The most conservative case estimated 66.2 m³/year per lineal metre of quarry under the full mined out condition. Once the quarry recovers to just 75 m of drawdown (as the water level recovers to 20 m above sea level), this value is reduced to 48.2 m³/year per lineal metre of quarry. Table 5 below summarizes what the inflow will be for each scenario along each quarry wall. The north wall is assumed to contribute nothing as it will have been removed by quarrying.

Table 5. Annual Maximum Groundwater Contributions into Quarry

Quarry Face	Length (m)	At Full Depth (@66.2 m ³ /yr/m)		After Closure (@48.2 m ³ /yr/m)	
		m ³ /yr	L/s	m ³ /yr	L/s
North	0	0	0	0	0
West	1,375	91,025	2.89	66,275	2.10
South	1,540	101,950	3.23	74,230	2.35
East	1,125	74,475	2.36	54,225	1.72
Total	4,040	267,450	8.48	194,730	6.17

These values are conservative in nature, as they are based on the most critical case of the bedrock being the same permeability for its entire depth. The inflow will be considerably lower for those portions where a lower hydraulic conductivity exists and the lateral extent of drawdown is smaller. In addition, as the quarry begins development the initial inflow amounts will be very small and will steadily build to the above estimates as the quarry expands and deepens.

3.7.3 Potential Effects on Wetlands and Streams

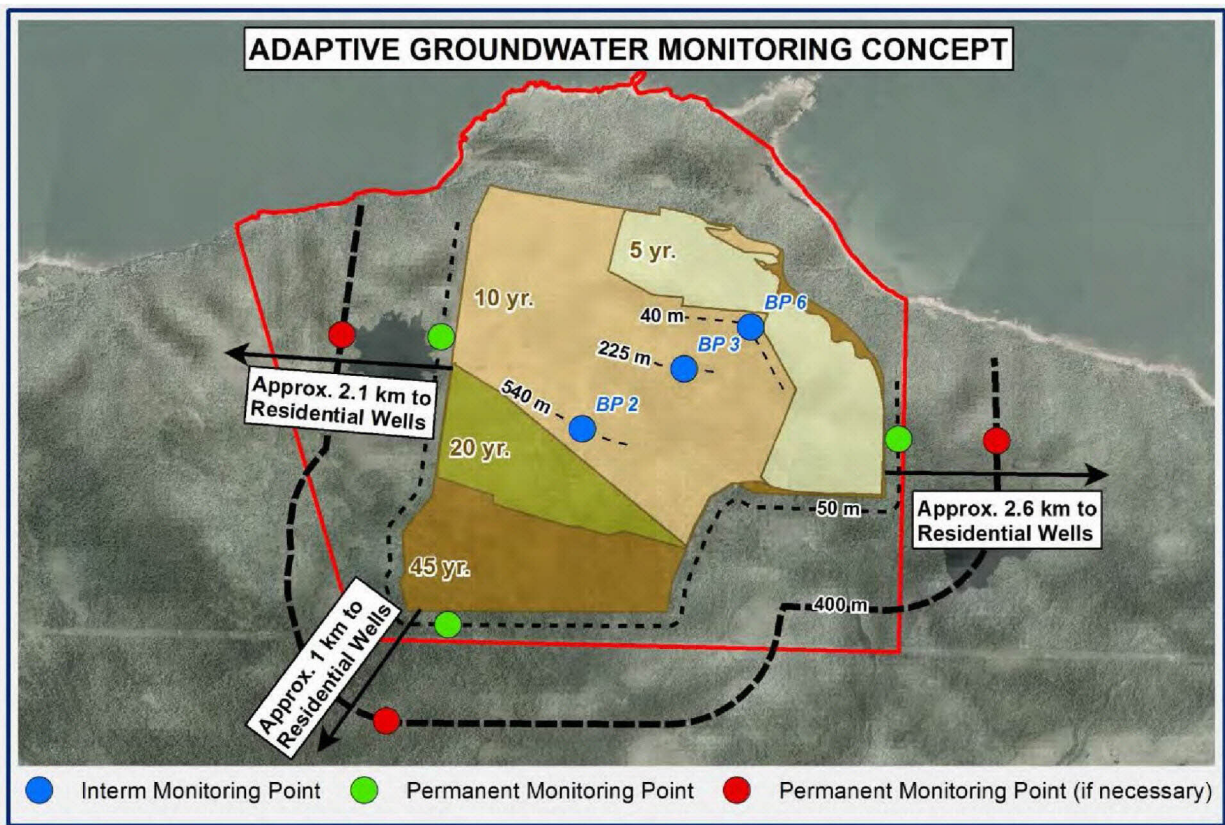

The potential effects of quarry drawdown in the subsurface on the watercourses or wetlands that lie inside the area so affected is considered here. This section does not deal with the reduction of catchment area for Reynolds Creek and other watercourses, which is presented in Section 6.0 of the Main Report. Section 3.4.1 above identified that the wetlands and streams on this site are generally "losing" systems. That is, there is a loss of surface water to the groundwater. Downward gradients dominate and are strong, whereas those few places with an upward gradient have only a weak upward gradient. This implies that these systems are surface water fed and not fed by groundwater discharge from the bedrock. Based on this there should be no depletion of these features by lowering of the water table in the underlying bedrock. It will be important to monitor these features as the quarry operations expand, and should impacts occur, mitigation and/or compensation can be undertaken.

3.7.4 Future Groundwater Monitoring

This section presents the foundation for confirmatory and precautionary groundwater monitoring of the site. The proposed monitoring program is based on the predicted effects of the quarry,

and will be adaptive to the conditions encountered as development proceeds and the quarry expands.

Due to the long term nature of the facility (50 year build out) the groundwater monitoring program will be phased in to establish background conditions as needed: the wells shown below would be installed over time, rather than all at once. As the results become known and actual quarry drawdowns are established and compared against predicted values, monitoring locations can be optimized or eliminated and monitoring frequency reduced if no effects are observed. It is anticipated that some monitoring locations will be temporary and will exploit existing boreholes (shown in blue, below) to help establish actual conditions, and that some will be permanent and newly installed (shown in green). The schematic below is intended to conceptually show what this would look like for the three areal phases of the Project.

Each groundwater monitoring station, both blue and green, would consist of at least a pair of drilled monitoring wells into the bedrock. One of the two wells will be equipped with a water level monitor in the upper 10 m of bedrock (the weathered zone), while the second well will be drilled to the anticipated final quarry depth. Packer testing would be used to select an appropriate permeable horizon within the deeper well to host the water level monitor. If the overburden is found to be substantive and water bearing, a shallow standpipe would be installed in the overburden for monitoring purposes.

The first blue sentry well pair would be drilled in year zero within the "10 yr zone", 50 m or less from the 5 year pit face. They are intended to establish the drawdown condition to the south. The first green sentry well pair would also be drilled in year zero and would be placed 50 m east of the quarry face since quarry expansion between years zero and five will occur in an easterly

direction. The objective of these wells is to monitor drawdown to the east. A third well pair (in red) would be installed 400 m east from the quarry face to test the predicted drawdown condition in year three or four, depending on the results recorded in the first well pair installed at 50 m. If no effects were measured at 50 m east, then no wells would be required at 400 m east.

All groundwater monitors would be tested for field permeability for comparison to the original studies. This information would be used to aid in the design of future monitoring stations. All other well pairs would be installed progressively over the years in keeping with quarry expansion. For example, the green well pairs to the west would be installed sometime after year five as the 10-year pit wall extent is approaching.

Groundwater monitoring would consist of seasonal (quarterly) water level measurements plus the use of dataloggers in key sentry wells in line with residential wells. Since no impacts are predicted on private wells over a kilometre away and there is a high level of confidence with this prediction, no private well monitoring program is proposed at this time. However, the groundwater monitoring program is adaptive and if drawdowns at the sentry wells were greater than predicted, additional sentry wells could be added and/or a private well monitoring program could be instituted if deemed necessary following discussions with NSE. Once seasonal baseline conditions (water quality and water level fluctuations) are established the results would be used to determine future seasonal water level monitoring frequency.

Two baseline water samples per year would be collected, one each in the wet and dry seasons. Samples would be analysed for a basic suite of water quality parameters. Water quality samples would be taken again if/when quarry effects are observed in the sentry wells to determine if the drawdown has had adverse effects on water quality. The need for future water quality sampling would be re-evaluated based on these initial results.

Each well location would undergo quarterly baseline monitoring for a minimum of two years to establish seasonal variations over differing meteorological conditions.

The monitoring of ground-to-surface water interaction will be achieved using the existing shallow drive point piezometers located in key wetlands plus in Fogherty and Murphys Lakes. The objective of this program is to establish if there is a drying out of wetlands from their baseline conditions. Water level monitoring would be undertaken at the same frequency as in the groundwater monitors but no water samples would be taken. This methodology is non-intrusive to the ecologic features and largely employs equipment already in place.

In summary, the groundwater monitoring approach is designed to verify the drawdown predictions described above. It will be progressively implemented as the quarry expands over time and has the additional advantage of being adaptive and flexible, in terms of well locations and monitoring efforts, to initial results. This in turn results in a groundwater monitoring program that is reflective of actual quarry expansion and measured Project effects on groundwater.

Drill Log Header Sheet

Hole: BP-7

Project	Black Point (6706)	Commenced	February.27 2014
Geologist	Peter Dalton, P.Geo.	Completed	March.1 2014
Designed By	Vulcan Materials	Drill Contractor	Logan Drilling Group
		Drill Rig	Duralite 1000N
		Drill Foreman	Andy McGinnis

Objective

Geological confirmation of the southeastern portion of the projected Black Point granitic resource.

Recovery Ave. %	98.80%
Recovery Range %	73% to 100%
Significant Core loss	0-0.54m

Geological Summary

BP-7 consists of a medium grained, moderately foliated, micaceous monzogranite. Mineralogy remains fairly consistent throughout the entire hole with 50% Plagioclase, 40% Quartz and 10% Mica (5% Biotite + 5% muscovite) although minor fluctuations in the mica component does occur. From 96m to 102m the monzogranite becomes relatively more potassic with the presence of orthoclase; the increase in orthoclase is sufficient enough to consider a lithology change to that of a syenogranite within this interval. This transition is subtle and represents mineralogical variations within the granite body and does not represent dyking or intrusive discontinuity. Alteration within BP-7 is limited to selective, weak chlorite alteration of biotite. The BP-7 monzogranite is a hard and competent rock with a limited structural component. A reoccurring, low angle joint + fracture orientation of 10-30° to core axis is present. Minor quartz and chlorite veinlets of the same orientation suggest this particular fracture set was a preferred conduit for fluid flow after pluton crystallization. Reoccurring micaceous clusters ~ 1-2cm² may also contribute to preferred zones of weakness within the granite as it was noted that mechanical fractures to the core during and post drilling tended to occur coincidentally with these clusters. Evidence of ground water flow and oxidation was noted to a depth of 5m. Observed mineralization is limited to trace amounts of pyrite occurring as a crust along a joint plane at 106m.

Drill Log Header Sheet

Hole: BP-8

Project Black Point (6706)
Geologist Peter Dalton, P.Geo.
Designed By Vulcan Materials

Commenced March.2 2014
Completed March.4 2014
Drill Contractor Logan Drilling Group
Drill Rig Duralite 1000N
Drill Foreman Andy McGinnis

Objective

Geological confirmation of the eastern portion of the projected Black Point granitic resource.

Location and Collar Detail

Datum UTM NAD 83 Zone 20
Easting(m) 645658
Northing(m) 5023133
Elevation(m) 63
Azimuth 0
Dip° -90
Depth(m) 108
Core Size NQ
RQD Ave. % 95.30%
RQD % Range 78.5% to 100%
Recovery Ave. % 99.20%
Recovery % Range 82% to 100%
Significant Core loss 0-0.36m

Geological Summary

The lithology of BP-8 is dominated by a medium grained equigranular, micaceous syenogranite to potassic monzogranite. The granite has a pervasive weak to moderate foliation indicated by alignment of biotite and in some cases quartz clasts. Mineralogy consists of 50% ($\pm 10\%$) Feldspar, 40% (± 5) Quartz and 7% ($\pm 5\%$) Biotite and $\pm 3\%$ Muscovite. The entire drill hole exhibits weak and selective chlorite alteration of the biotite. An oxidation zone occurs from 0-12m occurring as moderate to intense iron oxide staining associated along joint and fracture planes. Lithological variability within BP-8 occurs over two separate intervals: 20-21m and 34-39m; Both of these intervals represent zones of post crystalline, siliceous fluid flow within the granite body. These intervals are dominated by porphyritic textured quartz/feldspar breccia veins and stockworking. Breccia zone contacts with the syenogranite wall rock are abrupt at 50°CA. Abducted, angular clasts of wall rock and feldspar are visible within a aphanitic, siliceous quartz matrix suggesting a high energy emplacement. Vugs and cavities (3-9cm²) filled with euhedral quartz (1-3mm) associated with these intervals of breccia indicate high fugacity with this event. A pervasive low angle 10-30°CA vein and fracture set occurs throughout the entire hole represented by veins and fractures dominated by a combinations of \pm quartz, \pm chlorite alteration. Zones of intensified veining tend to exhibit orange iron oxide and limonite staining within vein salvage and joint planes suggesting oxidation of pyrite mineralization. Fresh pyrite mineralization (rare) was observed in trace concentrations along joint planes. Two zones of fault gouge were encountered between 93-95m. Granite from 95m to 108m(EOH) appears very fresh, hard and silicified with minimal fracture/jointing.

Geological Summary

The lithology of BP-9 is dominated by a medium grained equigranular, micaceous syenogranite to potassic monzogranite. The granite has a pervasive weak to moderate foliation indicated by alignment of biotite. Mineralogy consists of 50% ($\pm 10\%$) Feldspar, 40% ($\pm 5\%$) Quartz and 7% ($\pm 5\%$) Biotite and $\pm 3\%$ Muscovite. The entire drill hole exhibits weak and selective chlorite alteration of biotite. Lithological variability within BP-9 occurs over two separate intervals: 9-11m and 27-30m; Both of these intervals represent zones of highly silicified quartz-chlorite-feldspar porphyritic breccia (60-70% quartz and feldspar phenocrysts within an aphanitic quartz and chlorite matrix). Reoccurring low angle 5-30°CA vein and fracture sets dominated by combinations of \pm quartz, \pm chlorite alteration exist throughout the entire hole. The presence of iron oxide and limonite on various joint and fracture planes indicate the presence of oxidized pyrite. Rare, trace to weak intensity fresh pyrite mineralization was observed on various joint planes. Fault gouge was encountered between 20.32-20.72m. Granite from 102m to 130m(EOH) exhibits minimal fracture/jointing.

Canadian Water Quality Guidelines (CWQG) Protection for Aquatic Life (PAL) Freshwater Guidelines Update 7.0: Sep 2007

4. Aluminum Guideline (CWQG Aquatic Life - Freshwater): if pH < 6.5 then 0.005 mg/L (5 ug/L), else if pH >= 6.5 then 0.1 mg/L (100 ug/L)

5. Ammonia (CWQG Aquatic Life - Freshwater) - guidelines vary with pH and temperature. See fact sheet for details

6. Chloride Guideline value is for long term exposure. Short term exposure value is 640 mg/L

7. Copper Guideline (CWQG Aquatic Life - Freshwater): if CaCO₃ < 120 mg/L then 0.002 mg/L (2 ug/L), if CaCO₃ = 120-180 mg/L then 0.003 mg/L (3 ug/L), if CaCO₃ > 180 mg/L then 0.004 mg/L (4 ug/L),

8. Dissolved Oxygen Guideline (CWQG Aquatic Life - Freshwater): Warm-water biota (WWB) early life stages 6000 ug/L, WWB other life stages 5500 ug/L, Cold-water biota (CWB) early life stages 9500 ug/L, other life stages 6500 ug/L

9. Dissolved Oxygen Guideline (CWQG Aquatic Life - Marinewater): > 8000 ug/L

10. Pb Guideline (CWQG A.L. - Freshwater): if CaCO₃ < 60 mg/L then 0.001 mg/L, if CaCO₃ = 60-120 mg/L then 0.002 mg/L, if CaCO₃ = 120-180 mg/L then 0.004 mg/L, if CaCO₃ > 180 mg/L then 0.007 mg/L,

11. Ni Guideline (CWQG A.L. - Freshwater): if CaCO₃ < 60 mg/L then 0.025 mg/L, if CaCO₃ = 60-120 mg/L then 0.065 mg/L, if CaCO₃ = 120-180 mg/L then 0.110 mg/L, if CaCO₃ > 180 mg/L then 0.150 mg/L

12. Nitrate Canadian Water Quality Guidelines (CWQG) for Aquatic Life represents lower value for "Long Term Exposure". Short Term exposure values are 124 and 339 for Freshwater and Marine respectively

15. pH Guideline (CWQG Aquatic Life): Freshwater 6.5 - 9, Marine 7.0 - 8.7

16. Salinity Guideline (CWQG Aquatic Life - Marinewater): < 10% fluctuation.

17. Taste Aesthetic Objective (CDWQ): "Inoffensive"

18. Temperature Aesthetic Objective (CDWQ): <= 15°C

19. Calculated result only includes measured parameters. Actual TDS may be higher.

20. Elevated reporting limit due to sample matrix.

BOLD RED Exceeds guideline

NOTES:

NV = no value

Canadian Drinking Water Quality CDWQ Guidelines: Aug 2012

3. Aluminum Aesthetic Objective (CDWQ - AO): Conventional Treatment Plants = 0.1 mg/L (100 ug/L), Other Treatment Systems = 0.2 mg/L (200 ug/L)

4. pH Objective (CDWQ): 6.5 - 8.5

5. Calculated result only includes measured parameters. Actual TDS may be higher.

6. Sample results likely affected by water softener treatment system

BOLD RED Exceeds guideline

ATTACHMENT E
AECOM Technical Memo – June / July 2014 Fieldwork

Black Point Quarry Project
Guysborough County, NS
SLR Project No.: 210.05913.00000

Memorandum

To	Russell Dmytriw	Page 1
CC	Robert Till, Steve Usher	
Subject	Technical Memorandum: Black Point Hydrogeology June and July, 2014 Field Program	
From	Timothy Bachiu	
Date	September 23, 2014	Project Number 60323234

In support of an Environmental Assessment, hydrological and hydrogeological field work was completed by AECOM and SLR Consulting (Canada) staff at the Black Point Quarry site (the Site) in June and July, 2014. This memo documents field activities and presents data compiled from field tests and measurements completed during these field visits.

1. Residential Well Assessment

The objectives of the residential well assessment are:

- To establish baseline water quality.
- To determine the aquifer units used by residences for potable water supply.
- To provide a preliminary assessment of hydraulic parameters of aquifers near the proposed quarry.

A total of 14 residential wells within 4.0 km of the Site boundary were sampled and a subset of these wells was subjected to drawdown tests. At each residential well, a questionnaire was completed to document the type of well (drilled or dug), well completion details, water levels and whether the well user reported any issues with water quality or quantity. A yield test was completed on two wells, and two data loggers were deployed to monitor long term water levels.

Figure 1 identifies the locations of the residential wells and **Table 1** summarizes the information collected from the questionnaires.

mTOC* = meters below top of casing						

As shown on **Figure 1**, the area west of the Site along Half Island Cove Road utilizes dug wells for potable water. In July, water levels were within 3.0 m of the ground surface and no concerns of water quantity or quality were expressed. Two residents (BPRW003 and BPRW004) reported that springs emerge from the hill to the south of Half Island Cove Road.

A cluster of three residences is located southwest of the Site and utilize dug wells for potable water. Two of these residential wells were sampled and questionnaires were completed (BPRWA008, BPRWA013). Yield tests were not permitted at these residences due to concerns regarding temporary water supply shortages during the dry summer months.

A set of four cottages and one residence are located south of the Site. These dwellings are serviced by a drilled well completed in the Goldenville Formation metasedimentary bedrock. A yield test was completed on the drilled well. An unused drilled well is located ~30 m from the water supply well. The unused drilled well was monitored during the yield test and following the yield test was instrumented with a data logger recording at 15 minute intervals to monitor water levels over the longer term.

One well was sampled (BPRWA014) near Cavanaugh Lake. This shallow dug well has a reportedly high yield that may be related to the permeable sand and gravel associated with a nearby esker mapped on the provincial surficial geology map (Stea et al. 1992).

In the Fox Island Main area east of the Site, both dug and drilled wells are utilized for potable water supplies. The drilled wells are completed in the metasedimentary bedrock.

Results of the water quality analyses are presented in Table A1 (**Appendix A**). The water quality results indicate the water quality of dug and drilled wells meets the Canadian Drinking Water Quality Guidelines (CDWQ) for all parameters, with one exception. The drilled well sampled as BPRWA007 arsenic concentration (50 µg/L) exceeds the CDWQ for arsenic (10 µg/L).

Two yield tests were completed to provide a preliminary assessment of the hydraulic conductivity of the surficial deposits and the metasedimentary bedrock.

Yield Test 1

A yield test was completed at the sampling location BPRWA001 on Half Island Cove Road. Prior to the initiation of the yield test, the static water level and total depth were measured (**Table 1**), the dimensions of the well were measured (0.92 m diameter) and a data logger was installed to monitor the changes in water level. The well was pumped using the resident's jet pump and pressure tank system that provides water to the residence. An exterior tap was opened to allow water to flow for 1 hour. The flow rate (0.28 L/sec) was estimated by monitoring the length of time required to fill a container of known volume. The estimated total volume pumped from the well in 1 hour was 1,028 L. This volume would displace 1.55 m of water in the well, if no recovery occurred.

The data recorded during the test is presented in **Figure 3**. The maximum drawdown was 0.495 m. Recovery of 0.198 m of recovery was observed over a period of 1,110 minutes (18.5 hours). The data were analyzed using the Theis equation in Aqtesolv software and the results are presented in **Appendix B**. The curve was matched to the late recovery period. The drawdown data have considerable uncertainty because the true pumping rate in the well is not known and the pump may have been turned off and on intermittently during the pumping portion of the test as governed by the pressure tank. The initial recovery data appear to be influenced by the pump coming on from household use. The time of day corresponding to early recovery data is the early evening when household water use is expected. The portion of the data used to match the Theis curve corresponds to the overnight period when water usage is expected to be minimal. The estimated transmissivity of the unconsolidated surficial deposits that provide water to the well is $2.5 \times 10^{-6} \text{ m}^2/\text{sec}$, corresponding to a hydraulic conductivity of $8 \times 10^{-7} \text{ m/sec}$. These values are consistent with glacial till deposits in Nova Scotia and appear to represent a reasonable order of magnitude approximation.

Figure 3: BPRWA001 Yield Test Observations

Yield Test 2

A yield test was completed in the drilled well at the sampling station BPRWA007 located south of the site (**Appendix B**). A second drilled well is located approximately 30 m from the pumping well and was used as an observation well during the yield test. Both wells have a casing diameter of 15.2 cm and the total depth is estimated from the recollection of the residents. Prior to the yield test, the water levels of each well were measured. The water level in the pumping well was 11.83 meters below ground surface (mbgs) and the water level in the observation well was 9.21 mbgs at 13:00 on July 17, 2014.

A data logger (10 m depth range) was installed in the observation well at a depth of ~5 m below the water level and a second data logger (10 m depth range) was installed in the pumping well at a depth of ~9 m below the water level. The water supply system consists of a submersible pump in the well that transfers water to a holding tank. Water supply to the cottages/residence is drawn from the holding tank and when the holding tank water level is drawn down to a particular level, the pump in the well is turned on. Therefore, during the yield test, the pump was turned on several times. The data logger information from the yield test is presented in **Figure 4**.

Figure 4: BPRWA007 Yield Test observations

The well was pumped by the resident turning on the pump at the electrical board to measure the water level response. Drawdown in the pumping well exceeded 9 m within 300 seconds (5 minutes) of pumping. The water level was below the level of the data logger for 121 minutes from the initiation of the pumping. The data loggers were left in the wells overnight and retrieved the next morning. The most complete recovery occurred during the overnight hours. The observation well experienced a maximum drawdown of 0.87 m and displayed recovery of 0.77 m during the overnight period. The observation of drawdown at a well 30 m from the pumping well indicates the wells are hydraulically connected, likely through fractures in the bedrock.

The pumping rate during the test is not known and was not possible to estimate because of the configuration of the water supply system. Also, portions of the drawdown during the pumping were not captured by data logger because the depth range of the data logger did not allow for proper positioning. For these reasons, it is impractical to evaluate the data as a pumping test. To provide an approximation of the hydraulic conductivity, the most complete recovery curve is treated as a slug test. The recovery data was analyzed using the KGS method in Aqtesolv and results in a hydraulic conductivity of 5.8×10^{-8} m/sec (**Appendix B**).

2. Granite Hydrogeology

The hydrogeology of the granite for the proposed quarry was investigated by:

- Completing two water level (piezometric) surveys,
- Long term monitoring of water levels with data loggers,
- Completing four slug tests to estimate hydraulic conductivity, and
- Collecting water quality samples from four existing boreholes.

Boreholes locations are shown on **Figure 1**.

2.1 Piezometric Surveys

Eight exploration boreholes installed between 2007 and 2014 to assess the granite aggregate resource were used to complete piezometric surveys on June 5, 2014 and July 21, 2014. Results of the surveys are summarized in **Table 2**. The meters above sea level (masl) elevations in **Table 2** are from the borehole logs.

Table 2: Borehole Piezometric Surveys

Borehole ID	Elevation (masl) ¹	Total depth (m)	Stick up (m) ²	Water Level (mTOC) ³	Water Level (mbgs) ⁴	Water level elevation (masl) ¹	Water Level (mTOC) ³	Water Level (mbgs) ⁴	Water level elevation (masl) ¹

3 – mTOC: meters below the top of casing									
4 – mbgs: meters below ground surface									

2.2 Long Term Data Loggers

Pressure transducer data loggers were installed on June 5 in boreholes BP-5, BP-7, BP-8 and BP-9. The data loggers were programmed to collect readings at 15 minute intervals. Data were downloaded on July 21, compensated for barometric pressure and plotted in **Appendix C**.

Figure C1 displays fluctuations in water levels in BP-5 are up to 1.6 m and closely follow precipitation events, suggesting surface water enters the borehole at surface. This is consistent with observations from the field and the borehole completion. Bedrock is exposed at the surface at BP5 and the casing is not securely installed in the borehole.

Fluctuations in water levels of BP-7 are up to 4.0 m and also closely follow the precipitation events (**Figure C1**). Offsets in fluctuations and precipitation may be a result of a delayed response or the offsets may be a potential artifact produced from using daily precipitation data combined with relatively high frequency water level recordings (15 minute intervals). Field observations indicate the well is properly cased and no obvious pathways for surface water to enter the borehole were observed.

The long term water level data for BP-8 are presented on **Figure C2** to allow for a water level scale range that displays water level variations. The fluctuations in water level in BP-8 are a maximum of 0.16 m and are influenced by precipitation events in the same pattern as BP-7

The long term water level data for BP-9 are presented on **Figure C3** to allow for a water level scale range that displays water level variations. The fluctuations in water level in BP-9 are a maximum of 0.3 m and are influenced by precipitation events in a similar pattern as observed with BP-7.

These loggers will remain at these locations to collect long term data. Monthly manual water will be collected from all the boreholes to provide information on the seasonal variations of the groundwater table.

2.3 Granite Borehole Hydraulic Conductivity Tests

Preliminary hydraulic conductivity (k) tests were completed on four boreholes (BP-5, BP-7, BP-8 and BP-9) in the granite bedrock. The tests were completed using a 1.82 m long by 0.0381 m diameter slug with a total displacement volume of 2.07 L. The boreholes were drilled using NQ bits, resulting in a borehole diameter of 0.0757 m. The water displacement in the boreholes is calculated to be 0.47 m. The tests were completed using the following steps:

- Manual water level measurement.
- Preliminary testing of response using the slug and water level tape.
- Programming and installing data loggers at appropriate time interval and depth.
- Complete submersion (injection) of slug.
- Manual water level measurements to assess recovery.
- Removal (withdrawal) of slug from the borehole.
- Manual water level measurements to assess recovery.
- Retrieval of data logger and download of data.

BP-5 k-test

The static water level and total depth of BP-5 are included in **Table 2**. The maximum displacement recorded during the slug test was 0.44 m. The slug-out test was used to assess the hydraulic conductivity using the KGS method in Aqtesolv (**Appendix D**). The analysis indicates the hydraulic conductivity of BP-5 is 4×10^{-7} m/s.

BP-7 k-test

The static water level and total depth of BP-7 are included in **Table 2**. The maximum displacement recorded during the slug test was 0.05 m. The slug-out test was used to assess the hydraulic conductivity because the data logger was not installed during the slug in test. The small displacement recorded suggests the slug may not have been fully submerged or that the re-deployment of the data logger was not fast enough to record the initial part of the recovery. Using the limited data from the test, the Bouwer-Rice method in Aqtesolv was used to estimate a hydraulic conductivity of 2×10^{-6} m/s (**Appendix D**).

BP-8 k-test

The static water level and total depth of BP-8 are included in **Table 2**. The maximum displacement recorded during the slug test was 0.27 m. A rapid recovery was observed with static water level reached within 20 seconds. The slug withdrawal data were used to assess the hydraulic conductivity with Bouwer-Rice method in Aqtesolv. The hydraulic conductivity of BP-8 is estimated to be 1×10^{-5} m/s.

BP-9 k-test

The maximum displacement recorded during the BP-9 slug test was 0.47 m. Recovery to static water level occurred within 300 seconds. The slug injection portion of the test was used for analysis because the data logger became tangled with the slug rope when the slug was removed. The data were analyzed in Aqtesolv using the Bouwer-Rice method to estimate a hydraulic conductivity of 6×10^{-7} m/s.

The results of the slug test are documented in **Appendix D** and summarized in **Table 3**. These results provide a preliminary estimate of the bulk hydraulic conductivity of the granite. The results suggest some of the granite may be highly permeable, at least near surface, as represented by BP-8 and suggests the granite has a general hydraulic conductivity of 10^{-7} m/s. The hydraulic conductivity tests do not provide any insight to where the water is entering the well, but it is assumed the water entering the boreholes are from fractures intersecting the boreholes. The estimates of hydraulic conductivity do not provide any indication of the connectivity of the granite aquifer through the fracture network.

Table 3: Summary of Hydraulic Conductivity Tests

Borehole ID	Hydraulic conductivity (m/s)
BP-5	4×10^{-7}
BP-7	2×10^{-6}
BP-8	6×10^{-5}
BP-9	6×10^{-7}

2.4 Granite Groundwater Quality

Groundwater samples were collected from BP-5, BP-7, BP-8 and BP-9 using a bailer. Ten bailer volumes (~10 L) were removed from each borehole prior to sampling. The water quality samples were analyzed for general chemistry and total metals. Results of the water quality sampling are provided in Table A2 (**Appendix A**). The granite groundwater is high in aluminum and iron compared to the water samples collected from the bedrock wells completed in the metasedimentary bedrock (**Table A1**). The granite groundwater also contains dissolved total uranium concentrations ranging from 14 to 260 µg/L. These uranium values merit further investigation including re-sampling with a more thorough purge of the borehole and review of core logs and core bulk chemistry.

3. Surface Water and Wetlands

The surface water and wetlands at the Site were investigated by completing:

- Stream flow measurements.
- Stream water sampling.
- Installation of mini-piezometers in wetlands.

3.1 Stream Flow Measurements

The stream locations investigated during the hydrogeology field program are identified on **Figure 2**.

Stream flows were measured July 25, 30 and 31, 2014 and are representative of dry (baseflow) conditions (no precipitation for the three days preceding discharge measurements). The area-velocity method was used to determine stream discharge. Discharge (Q) is calculated as the product of the mean stream velocity (V) and the cross-sectional area (A) of the channel; or $Q=VA$. Velocity measurements were taken at selected intervals across the channel cross-section. Stream velocity was measured using a Marsh McBirney Flo-Mate current meter. At each interval, the current meter operator measured water depth and mean velocity. Mean velocity measurements were taken at 0.6 of the depth and were observed for 40 seconds.

3.1.1 Stream Descriptions

BPSTR06

The discharge measurement at BPSTR06 was measured approximately 10 m downstream from the discharge of Fogherty Lake. The channel width varied from approximately 0.50 to 1.0 m, depth up to 0.3 m and had a moderate slope. The stream bed substrate consisted of gravel and boulders scattered throughout. The discharge measurement section was 0.50 m wide, well-defined with boulders at each bank, and had consistent flow throughout the entire section as shown in **Appendix E**.

BPSTR08

No discharge measurement was completed at BPSTR08 due to marginal/zero-flow conditions. BPSTR08 is located in a small headwater stream with sand, gravel and cobbles in the stream bed.

BPSTR09

The discharge measurement at BPSTR09 was measured approximately 20 m downstream of the discharge from Murphys Lake. The typical channel width was 1.0 m or less and had a moderate slope. The stream bed was muddy with fine gravel. The discharge measurement section was 0.80 m

wide, had well-defined banks on each side, and had consistent flow throughout the entire section. The cross section of the stream flow measurement location is shown in **Appendix E**.

BPSTR10

The discharge measurement at BPSTR10 was located 2.0 km east of the Site boundary and was measured approximately 10.0 m upstream from the bridge crossing at Starks Road. The typical full-bank channel width was approximately 3.0 m wide and a moderate slope. The stream was in low-flow conditions at the time of measurement. The stream bed substrate consisted of a mix of gravel, cobbles and boulders. The discharge measurement section was 1.1 m wide, well-defined with boulders at each bank, with flow concentrated primarily in middle of the cross-section and negligible at the banks.

BPSTR12

The discharge measurement at BPSTR12 was measured where a wetland (WL1) on the southeast portion of the Site outflows and crosses an ATV trail. The channel was 2.0 to 10.0 m wide with low, gradual banks, and moderate slope. The stream bed consisted primarily of a mix of sand, cobbles and boulders. The discharge measurement was located at a narrow, well-contained section 1.0 m wide with boulders on each side, and consistent flow throughout the section.

Table 4 presents a summary of the stream discharge measurements.

Table 4: Stream Discharge Summary

ID	Location Description	Discharge (L/s)	Date Measured
BPSTR06	Fogherty Lake Outflow	0.031	July 30
BPSTR08	Wetland 17 Inflow	n/a	n/a
BPSTR09	Murphys Lake Outflow	0.170	July 31
BPSTR12	Wetland 1 Outflow	7.73	July 31
BPSTR10	Fox Island Creek Outflow	4.24	July 25

3.2 Stream Water Samples

Stream water samples were collected at locations BPSTR06, BPSTR08, BPSTR09, BPSTR10 and BPSTR12 just prior to taking the flow measurements. Stream samples were analyzed for general chemistry and total metals. Results are included in **Appendix A**.

3.3 Mini-piezometers

Mini-piezometers (MPs) were installed in wetlands and streams to assess the vertical gradient of shallow groundwater. In wetlands, the mini-piezometers were installed as nested pairs with one deep and one shallow piezometer. In streams, one mini-piezometer was installed in the stream bed. The locations of the mini-piezometers are identified in **Figure 2**. One wetland pair (MP2) and one stream mini-piezometer (MP6) were instrumented with a data logger to record water levels and temperature at 15 minute intervals over the longer term.

Mini-piezometer sizes were 1.9 cm (¾") and 2.54 (1") diameters. Galvanized steel pipe and couplers were used to construct the piezometers. Teflon tape was used on all pipe threads to ensure water-

tight seals at the joints of the piezometers. The pipe was next hand-tightened into the piezometer tip, and then tightened to finish, using two 18" pipe wrenches. A coupler and pipe were then added to the piezometer using the same method as described above. Measurements were then taken of the length of the screen interval, the length from the bottom of the screen interval to the top of the MP tip, and the length from the top of the tip to the top of the first coupler.

A fence post driver was then used to hammer the piezometer into the ground. In wetland areas, where sphagnum moss and peat layered bedrock were encountered, the piezometers were easily pushed to refusal by hand. In areas where the soil consisted of boulders and packed gravel, it was very difficult to hammer the piezometers into the ground - on occasion several locations were attempted before a suitable location was found. As the piezometer was hammered further into the ground, subsequent couplers and pipes were added, as necessary, with measurements between coupler tops taken each time. Once hammered to refusal, the length of pipe sticking up above the ground was measured.

A differential survey was then completed using a rod and level. Three permanent benchmarks were installed at each site. Benchmarks consisted of either a nail hammered into a tree and marked by spray paint and flagging, or a location on a sturdy boulder marked by spray paint.

Water levels were measured in some of the mini-piezometers following installation, but these measurements are not considered to be representative of equilibrated, static water level conditions and should not be used to estimate the vertical hydraulic gradient. Water level measurements and logger downloads will be completed at all MP's and existing boreholes on the site at a minimum in the fall of 2014, spring of 2015 and summer of 2015.

Completion details of the MPs are summarized in **Table 5** and the locations of the MPs are identified on **Figure 2**.

Table 5: Summary of Mini-piezometer Completions

Mini piezometer	UTM		Pipe diameter (cm)	Bottom of perforated interval	Top of perforated interval	DL	Stick up	water level
	Easting	Northing		(mbgs)	(mbgs)

nm - not measured								
mbgs – meters below ground surface								

MP 1

MP 1 is located in a wetland west of Fogherty Lake. The wetland was relatively dry at the time of installation. Thick sphagnum moss and peat is found to a depth > 1.5 m. Bedrock was consistently encountered at a depth of ~ 3 m in this area.

MP2

MP 2 is located in a wetland south of Fogherty Lake. Thick sphagnum moss and peat is found to a depth > 1.5 m. Bedrock was consistently encountered at a depth of 2 to 2.5 m in the wetland.. Both the shallow and deep piezometers are instrumented with data loggers.

MP3

MP3 is located east of Fogherty Lake. Thick sphagnum moss and peat is found to a depth > 1.5 m. Bedrock was consistently encountered at a depth of 2 to 3 m in the wetland area.

MP4

MP4 is located in a small wetland area in the eastern portion of the property. Topography indicates the wetland drains to Murphys Lake. The wetland was wetter than those hosting the MPs installed near Fogherty Lake. Outcrops of bedrock are visible within 50.0 m of MP4. Bedrock was encountered at a depth of ~ 3 m.

Photo 1: MP4

MP5

MP5 is located in a large wetland area at the southern end of the property. The wetland feeds a stream discharging to the south (BPSTR012 stream monitoring location). Thick sphagnum moss and peat is found to a depth >1.5 m. Bedrock depth is variable from 1.5 m to 3.5 m.

Photo 2: MP5

MP6

MP6 is a single 1 inch piezometer installed in the stream discharging from Fogherty Lake. The stream bed has sand, gravel, cobbles and boulders. Piezometer refusal was common at a depth of 0.5 m. Stream flow measurement, surface water sampling and field parameters measurements were completed at MP6. The piezometer is instrumented with a data logger.

Photo 3: MP6 with Data Logger

MP7

MP7 is located in a northwest trending lineament with ~ 10 m of relief, which is 5 to 10 m wide. No water was running at the location and there is no indication of a stream bed. A nested set of MPs were installed. Moss is found to a depth of 0.5 m, followed by sediment/till. Bedrock/piezometer refusal was not encountered, but piezometer insertion was increasingly difficult past the first pipe length.

Photo 4: MP7

MP8

MP8 is single piezometer located in a small stream in the southeastern portion of the property. The stream bed is composed of sand, gravel, cobbles and boulders. Piezometer refusal was common at a depth of < 0.5 m. Stream flow was negligible and a flow measurement was not completed. A surface water sample was collected.

MP9

MP9 is a single piezometer installed in the stream discharging from Murphys Lake. The stream bed is muddy with sand and cobbles beneath the mud. A stream flow measurement was made, surface water sample collected and field parameters recorded.

4. Summary

Field activities completed in support of the Black Point Quarry environmental assessment provide preliminary information to assess the hydrology and hydrogeology of the Site. Key findings from the field program include:

- There are no residential wells completed in the quarry granite.
- Residences west of the Site utilize dug wells to access potable water.
- Four residences (one south and three east of the Site) utilize drilled wells to obtain potable water.
- The groundwater elevation in the granite is between 53 and 93 masl.
- The granite groundwater exhibits elevated metals including uranium, relative to stream water samples.
- The granite hydraulic conductivity ranges from 10^{-5} m/s to 10^{-8} m/s.

Follow up monitoring should include:

- Mini-piezometer water level measurements in the fall, spring, and summer.
- Downloading of borehole data loggers in the fall, spring, and summer.
- Sampling from the boreholes using a pump to purge the wells prior to sampling.
- A repeat hydraulic conductivity test (k-test) of BP-7.

Canadian Water Quality Guidelines (CWQG) Protection for Aquatic Life (PAL) Freshwater Guidelines Update 7.0: Sep 2007

1. Duplicate sample is BPSTR011

4. Aluminum Guideline (CWQG Aquatic Life - Freshwater): if pH < 6.5 then 0.005 mg/L (5 ug/L), else if pH >= 6.5 then 0.1 mg/L (100 ug/L)

5. Ammonia (CWQG Aquatic Life - Freshwater) - guidelines vary with pH and temperature. See fact sheet for details

6. Chloride Guideline value is for long term exposure. Short term exposure value is 640 mg/L

7. Copper Guideline (CWQG Aquatic Life - Freshwater): if CaCO₃ < 120 mg/L then 0.002 mg/L, if CaCO₃ = 120-180 mg/L then 0.003 mg/L, if CaCO₃ > 180 mg/L then 0.004 mg/L

8. Dissolved Oxygen Guideline (CWQG A.L. - Freshwater): Warm-water biota early life stages 6000 ug/L, other life stages 5500 ug/L, Cold-water biota early life stages 9500 ug/L, other life stages 6500 ug/L

9. Dissolved Oxygen Guideline (CWQG Aquatic Life - Marinewater): > 8000 ug/L

10. Pb Guideline (CWQG A.L. - Freshwater): if CaCO₃ < 60 mg/L then 0.001 mg/L, if CaCO₃ = 60-120 mg/L then 0.002 mg/L, if CaCO₃ = 120-180 mg/L then 0.004 mg/L, if CaCO₃ > 180 mg/L then 0.007 mg/L

11. Ni Guideline (CWQG A.L. - Freshwater): if CaCO₃ < 60 mg/L then 0.025 mg/L, if CaCO₃ = 60-120 mg/L then 0.065 mg/L, if CaCO₃ = 120-180 mg/L then 0.110 mg/L, if CaCO₃ > 180 mg/L then 0.150 mg/L

12. Nitrate Canadian Water Quality Guidelines (CWQG) for Aquatic Life represents lower value for "Long Term Exposure". Short Term exposure values are 124 and 339 for Freshwater and Marine respectively

- 15. pH Guideline (CWQG Aquatic Life): Freshwater 6.5 - 9, Marine 7.0 - 8.7
 - 16. Salinity Guideline (CWQG Aquatic Life - Marinewater): < 10% fluctuation.
 - 17. Taste Aesthetic Objective (CDWQ): "Inoffensive"
 - 18. Temperature Aesthetic Objective (CDWQ): <= 15°C
 - 19. Calculated result only includes measured parameters. Actual TDS may be higher.
- BOLD RED**

AECOM Technical Memo – August 2014 Fieldwork

Black Point Quarry Project
Guysborough County, NS
SLR Project No.: 210.05913.00000

Memorandum

To	Russell Dmytriw	Page 1
CC	Robert Till, Steve Usher	
Subject	Technical Memorandum: Black Point Hydrogeology August, 2014 Field Program	
From	Timothy Bachiu	
Date	September 23, 2014	Project Number 60323234

Field work in support of the hydrological and hydrogeological assessments of the proposed Black Point Quarry site was completed by AECOM and SLR Consulting (Canada) staff from August 25-29, 2014. This memo documents field activities and presents data compiled from field tests and measurements completed during the late August field event.

1. Mini-Piezometers

Mini-piezometers were installed at nine (9) locations as documented in the AECOM Technical Memorandum dated August 15, 2014. Water levels in each mini-piezometer (MP) were subsequently measured on August 26 and 27 (**Table 1**). The difference in water levels (DH) at each piezometer location is calculated by subtracting the water level (meters below ground surface – mbgs) in the deep MP from the water level in the shallow MP. Negative values indicate the water level in the deeper MP is lower than the shallow MP. The difference in the depth of the screened intervals (DL) is calculated as the difference between the deepest part of the screen in the shallow MP and depth of the upper limit of the screen in the deep MP. The vertical gradient is calculated by dividing the difference in the water levels by the DL (DH/DL). Negative values indicate a downward vertical gradient and positive values indicate an upward vertical gradient.

Table 1: Water Levels

Mini piezometer ID	Bottom of perforated interval	Top of perforated interval	Vertical separation of screened intervals (DL)	Stick up	Water Level			Vertical gradient
	(mbgs)	(mbgs)	(m)	(m)	(m below top of pipe)	(mbgs)	Difference (shallow - deep)

MP7 shallow	1.719	1.369	1.07	1.11	1.186	0.076	0.016	0.01
MP7 deep	3.14	2.789		0.904	0.964	0.06		
MP8 stream	0	n/a	0.44	0.796	0.736	-0.06	-0.146	-0.33
MP8 deep	0.79	0.44		0.796	0.882	0.086		
MP9 stream	0	n/a	1.003	1.46	1.335	-0.125	0.03	0.03
MP9 deep	1.353	1.003		1.46	1.305	-0.155		

Mini-piezometers at MP 2 (deep and shallow) and MP6 (deep and stream) contained data loggers installed during a previous site visit. Recorded data from these MPs are provided in the spreadsheet **Appendix A**.

2. Granite Boreholes

A water level survey of all granite boreholes was completed between August 25 and 28. Water level measurements collected in June, July and August 2014 are provided in Table 2. Data loggers were retrieved, downloaded and replaced. Barometrically compensated data and charts from each data logger are provided in the spreadsheet **Appendix B** in the files accompanying this memorandum.

Short term pumping tests were completed and water quality samples were collected from granite boreholes BH5, BH7, BH8 and BH9. Prior to pump installation, a data logger with 30 m depth range was installed in the well at depth or approximately 2 m below the anticipated pump intake depth. The pump was installed and water was pumped from each borehole using a 12 Volt submersible pump powered by a 12 Volt marine battery.

The pumping test at BH5 was completed on August 28, 2014. Water was pumped from the borehole for approximately 135 minutes at a rate of 6.2 L/minute. Maximum drawdown approximately 3 m. After the pumping was completed, recovery was monitored until 85% of the drawdown had recovered.

The pumping test at BH7 was completed on August 28, 2014. Water was pumped from the borehole at two intervals of 15 minutes at a rate of 5.7 L/minute. The maximum drawdown observed was 1.4 m. Recovery was monitored for 25 minutes, during which 59% of displacement recovery was observed. During the second portion of the pumping, the pump was malfunctioning and did not operate consistently.

The pumping test at BH8 was completed on August 28, 2014. Water was pumped from the borehole for 135 minutes at a rate of 3.2 L/minute. The maximum drawdown observed was 1.05 m. Recovery was monitored for 12 minutes, during which 41 % of recovery was observed.

The pumping test at BH9 was completed on August 28, 2014. Water was pumped from the borehole for 99 minutes at a rate of 2.6 L/minute. The maximum drawdown observed was 1.63 m. Recovery was monitored for 44 minutes, during which 75% of recovery was observed.

Field parameters were measured at fifteen minute intervals during the pumping tests. The final field parameter measurements prior to sampling are in Table 3. Also included in Table 3 for comparison are the field parameters measured from residential wells and streams.

BPSTR10	21.8	53	3.36

Data logger recorded observations are provided and graphed in the excel spreadsheet **Appendix C** accompanying this memo.

3. Stream Flow Measurements

Stream flow observations and measurements were completed on August 26 and 27 (**Table 3**). The area-velocity method was used to determine stream discharge at BPSTR10. Discharge (Q) is calculated as the product of the mean stream velocity (V) and the cross-sectional area (A) of the channel; or $Q=VA$. Velocity measurements were taken at selected intervals across the channel cross-section. Stream velocity was measured using a Marsh McBirney Flo-Mate current meter. At each interval, the current meter operator measured water depth and mean velocity. Mean velocity measurements were taken at 0.6 of the depth and were observed for 40 seconds. The flow at BPSTR12 was minimal. A single flow measurement was made using the flow meter at a 5 cm by 5 cm notch where flow was observed. Observations and flow measurements are recorded in the excel spreadsheet **Appendix D** accompanying this memo.

Table 3: Flow

Stream ID	Discharge (L/s)	Date and Time	Stream Conditions
BPSTR06	N/A	Aug 27, 10:00	No measurable flow
BPSTR08	N/A	Aug 26, 16:00	No measurable flow
BPSTR09	N/A	Aug 27, 17:00	No measurable flow
BPSTR10 (Fox Island Main)	0.394	Aug 27, 11:30	Very low flow
BPSTR12	0.325	Aug 27, 15:20	Very low flow

4. Residential Wells

Work completed to assess residential wells included:

- Yield test and a second sampling event at 79 Fox Island Main Road.
- Collection of two water samples at 3421 Highway 16.
- Collection of one water sample at 2927 Highway 16.

The yield test at 79 Fox Island Main Road was completed on August 29, 2014. Two drilled wells, located side by side, are present at this location. A data logger was installed into the drilled well with the pump and water was discharged from the exterior tap for approximately 1 hour. Drawdown is observed to occur in steps which are interpreted to be a result of the pump switch on and off as governed by the in-house pressure tank. Total maximum drawdown was 1.7 m. Recovery was monitored for a period of 120 minutes and recharge of 0.19 m was observed before the data logger

was retrieved (**Figure 1**). Complete data of the yield test can be found in excel file **Appendix E** accompanying this memo.

One water quality sample (BPRWA016) was collected at the end of the yield test and submitted to Maxxam for analysis. Results are presented in **Appendix D**.

Two water quality samples (BPRWA007_A, BPRWA007_B) were collected from 3421 Highway 16 on August 28. Sample analyses were completed on one of the samples as unfiltered (BPRWA007_A), and one sampled after in-laboratory filtering (BPRWA007_B) and results are presented in **Appendix D**.

One water quality sample (BPRWA017) was collected from 2927 Highway 16. are presented in **Appendix D**

Figure 1: Water Level above the Datalogger during the Yield Test at 79 Fox Island Main Road

UTM coordinates of residential wells collected in August are summarized in Table 4.

APPENDIX B
Acid Rock Drainage Potential Report (2011)

Black Point Quarry Project
Guysborough County, NS
SLR Project No.: 210.05913.00000

November 15, 2011

Submitted By: Peter Dalton

Purpose

To determine the potential for Acid Rock Drainage (ARD) related to the bedrock underlying the processing area at the proposed Black Point Aggregate project site.

Introduction

Erdene Resource Development's Black Point aggregate project is located approximately 10km west of Canso along the southern coast of the Chedabucto Bay, Guysborough County, Nova Scotia.

On October 27, 2011 Erdene geologists Mark Davies and Peter Dalton completed a one day geologic mapping and sampling program focused over the industrial footprint of the project site proposed for aggregate processing and marine load out facilities. Six representative rock samples were collected from both outcrop and subcrop located over the area of interest. All samples were submitted for sulphide concentration and acid producing potential analysis. Of the six samples collected only one sample (BP-ARD-5) exhibited intense sulphide (pyrite) mineralization suggesting the potential for acid production.

Geology

The central portion of the Black Point project area is dominated by a Devonian aged monzogranite pluton which intruded Ordovician aged metasedimentary units of both the Halifax and Goldenville Formations which comprise the Meguma Group (see Figure 1). The granite is the rock intended to be mined as construction aggregate. Most infrastructure related to aggregate processing would be constructed on the coastal platform comprised of the Halifax and Goldenville Formations in the northern portion of the project area.

Granite- Medium grained, equigranular, micaceous monzogranite

Halifax Formation- Highly foliated metawacke and slates. Commonly sulphide (pyrite) bearing.

Goldenville Formation- Silicified quartzites, minor interbeds of highly foliated shales and metawacke.

Discussion

A representative suite of six rock samples were collected over the proposed processing facility area at Black Point. An attempt to collect all samples from outcrop was not possible based upon the heavy surficial cover.

Samples from the Goldenville formation was exclusively collected from outcrop locations. The silicified weather resistive nature of the quartzite provide outcrops of prominent ridges and topographic highs.

Sampling related to the Halifax Formation was not sourced from outcrop but rather cobble sized material interpreted to be subcrop collected from within a small stream bed near the bottom of the prominent slope that rises in elevation towards the granite to the south.

Goldenville Formation

All samples related to the Goldenville Formation remained consistent in regards to lithology. Samples consisted of silicified, very fine grained to aphanitic, well indurated quartzite. Variations observed included weak manganese staining and trace concentrations of oxidized pyrite.

Halifax Formation

The representative sample of the Halifax Formation consisted of a highly foliated slate with moderate intensity iron oxide staining on the weathered surface. The fresh surface exhibited $\leq 5\%$ pyrite mineralization occurring as clumps along cleavage planes.

BP-ARD-5 Halifax Formation

The most up to date geology map of the Black Point area is associated with the GSC Bulletin 383 by J.D. Hill, 1991. Mapping completed by Erdene geologists of the Goldenville and Halifax Formations at Black Point suggests a slight discrepancy when compared to the geology map indicated by J.D. Hill. Where Hill has mapped a geologic boundary between the Goldenville and the Halifax Formations Erdene geologist found evidence to suggest that the Goldenville quartzites extend further south (see Figure 2). This evidence is based on outcropping quartzite located at BP-ARD-4 clearly located within what was previously mapped as Halifax Formation metawacke.

Methodology and Laboratory Testing

All samples were either directly collected from outcrop or subcrop using a 2-5kg sample volume. Samples were cleared of any obvious organic debris to minimized contamination.

All samples were submitted to the Dalhousie University Minerals Engineering Center Laboratory in Halifax, Nova Scotia. Sample Analysis consists of the **BC Research Initial Test Method** which consists of:

Total Sulphur- weight %

*Total Sulphide-weight % (BP-ARD-1 and BP-ARD-5)

Acid Producing Potential- kg/tonne H₂SO₄

Acid Consuming Ability- kg/tonne H₂SO₄

pH

*Total Sulphide analysis was completed for sample BP-ARD-1 which represented the Goldenville quartzite sample with the highest total sulphur value and BP-ARD-5 which represents the Halifax pyritic slate.

Complete results of the ARD sampling are located in Appendix 1

Conclusion

A suite of six rock samples were collected from the proposed processing and marine load out area at the Black Point project location in Guysborough County, Nova Scotia to determine their acid producing potential. The samples collected represent both the Goldenville Formation quartzite and Halifax Formation slate which underlie the area of interest. Of these six samples collected only one sample (BP-ARD-5) collected from the Halifax Formation feature increased sulphur/sulphide concentrations in hand specimen. These samples were submitted to Dalhousie

University's Minerals Engineering Laboratory for sulphur and sulphide analysis by BC Research Initial Test method.

Geology	S (Total wt%) Ave.	S (Sulphide)wt%	Acid Prod. Potential Ave. kg/t H₂SO₄	Acid Cons. Ability Ave.	pH Ave.
Goldenville Quartzite	0.0114	0.009	0.29	4.012	8.06
Halifax Slate/Metawacke	1.0	0.935	28.60	4.61	7.4

Results indicate that the Goldenville quartzite pose no risk of acid production under meteoric conditions. The Halifax Formation slate and metawacke contains abundant concentrations of sulphide (pyrite) which elevates the acid producing potential of the rock to 28.60 kg/t H₂SO₄. It is interesting to note that although sample BP-ARD-5 contained abundant sulphide concentrations the overall pH of the sample was neutral to basic at 7.4.

Based upon these findings future steps of mitigation may be necessary in order to minimize acid rock drainage related of the Halifax Formation slates should the local bedrock become disturbed during infrastructure development.
